- `client` – **[in]** Client instance for which the procedure is requested. Shall not be NULL.

**Returns** 0 or a negative error code (`errno.h`) indicating reason of failure.

int mqtt\_read\_publish\_payload(struct [mqtt\\_client](#) \*client, void \*buffer, size\_t length)

Read the payload of the received PUBLISH message. This function should be called within the MQTT event handler, when MQTT PUBLISH message is notified.

---

**Note:** This is a non-blocking call.

---

**Parameters**

- `client` – **[in]** Client instance for which the procedure is requested. Shall not be NULL.
- `buffer` – **[out]** Buffer where payload should be stored.
- `length` – **[in]** Length of the buffer, in bytes.

**Returns** Number of bytes read or a negative error code (`errno.h`) indicating reason of failure.

int mqtt\_read\_publish\_payload\_blocking(struct [mqtt\\_client](#) \*client, void \*buffer, size\_t length)

Blocking version of [mqtt\\_read\\_publish\\_payload](#) function.

**Parameters**

- `client` – **[in]** Client instance for which the procedure is requested. Shall not be NULL.
- `buffer` – **[out]** Buffer where payload should be stored.
- `length` – **[in]** Length of the buffer, in bytes.

**Returns** Number of bytes read or a negative error code (`errno.h`) indicating reason of failure.

```
int mqtt_readall_publish_payload(struct mqtt\_client *client, uint8_t *buffer, size_t length)
```

Blocking version of [mqtt\\_read\\_publish\\_payload](#) function which runs until the required number of bytes are read.

#### Parameters

- `client` – **[in]** Client instance for which the procedure is requested. Shall not be NULL.
- `buffer` – **[out]** Buffer where payload should be stored.
- `length` – **[in]** Number of bytes to read.

**Returns** 0 if success, otherwise a negative error code (`errno.h`) indicating reason of failure.

```
struct mqtt_utf8
```

*#include <mqtt.h>* Abstracts UTF-8 encoded strings.

#### Public Members

```
const uint8_t *utf8
```

Pointer to UTF-8 string.

```
uint32_t size
```

Size of UTF string, in bytes.

```
struct mqtt_binstr
```

*#include <mqtt.h>* Abstracts binary strings.

#### Public Members

```
uint8_t *data
```

Pointer to binary stream.

```
uint32_t len
```

Length of binary stream.

```
struct mqtt_topic
```

*#include <mqtt.h>* Abstracts MQTT UTF-8 encoded topic that can be subscribed to or published.

#### Public Members

```
struct mqtt\_utf8 topic
```

Topic on to be published or subscribed to.

```
uint8_t qos
```

Quality of service requested for the subscription. [mqtt\\_qos](#) for details.

```
struct mqtt_publish_message
```

*#include <mqtt.h>* Parameters for a publish message.

## Public Members

struct *mqtt\_topic* topic

Topic on which data was published.

struct *mqtt\_binstr* payload

Payload on the topic published.

struct mqtt\_connack\_param

*#include <mqtt.h>* Parameters for a connection acknowledgment (CONNACK).

## Public Members

uint8\_t session\_present\_flag

The Session Present flag enables a Client to establish whether the Client and Server have a consistent view about whether there is already stored Session state.

enum *mqtt\_conn\_return\_code* return\_code

The appropriate non-zero Connect return code indicates if the Server is unable to process a connection request for some reason.

struct mqtt\_puback\_param

*#include <mqtt.h>* Parameters for MQTT publish acknowledgment (PUBACK).

struct mqtt\_pubrec\_param

*#include <mqtt.h>* Parameters for MQTT publish receive (PUBREC).

struct mqtt\_pubrel\_param

*#include <mqtt.h>* Parameters for MQTT publish release (PUBREL).

struct mqtt\_pubcomp\_param

*#include <mqtt.h>* Parameters for MQTT publish complete (PUBCOMP).

struct mqtt\_suback\_param

*#include <mqtt.h>* Parameters for MQTT subscription acknowledgment (SUBACK).

struct mqtt\_unsuback\_param

*#include <mqtt.h>* Parameters for MQTT unsubscribe acknowledgment (UNSUBACK).

struct mqtt\_publish\_param

*#include <mqtt.h>* Parameters for a publish message.

## Public Members

struct *mqtt\_publish\_message* message

Messages including topic, QoS and its payload (if any) to be published.

uint16\_t message\_id

Message id used for the publish message. Redundant for QoS 0.

uint8\_t dup\_flag

Duplicate flag. If 1, it indicates the message is being retransmitted. Has no meaning with QoS 0.

uint8\_t retain\_flag

Retain flag. If 1, the message shall be stored persistently by the broker.

struct mqtt\_subscription\_list

*#include <mqtt.h>* List of topics in a subscription request.

### Public Members

struct *mqtt\_topic* \*list

Array containing topics along with QoS for each.

uint16\_t list\_count

Number of topics in the subscription list

uint16\_t message\_id

Message id used to identify subscription request.

union mqtt\_evt\_param

*#include <mqtt.h>* Defines event parameters notified along with asynchronous events to the application.

### Public Members

struct *mqtt\_connack\_param* connack

Parameters accompanying MQTT\_EVT\_CONNACK event.

struct *mqtt\_publish\_param* publish

Parameters accompanying MQTT\_EVT\_PUBLISH event.

---

**Note:** PUBLISH event structure only contains payload size, the payload data parameter should be ignored. Payload content has to be read manually with *mqtt\_read\_publish\_payload* function.

---

struct *mqtt\_puback\_param* puback

Parameters accompanying MQTT\_EVT\_PUBACK event.

struct *mqtt\_pubrec\_param* pubrec

Parameters accompanying MQTT\_EVT\_PUBREC event.

struct *mqtt\_pubrel\_param* pubrel

Parameters accompanying MQTT\_EVT\_PUBREL event.

struct *mqtt\_pubcomp\_param* pubcomp

Parameters accompanying MQTT\_EVT\_PUBCOMP event.

struct *mqtt\_suback\_param* suback

Parameters accompanying MQTT\_EVT\_SUBACK event.

struct *mqtt\_unsuback\_param* unsuback

Parameters accompanying MQTT\_EVT\_UNSUBACK event.

struct mqtt\_evt

*#include <mqtt.h>* Defines MQTT asynchronous event notified to the application.

### Public Members

enum *mqtt\_evt\_type* type

Identifies the event.

union *mqtt\_evt\_param* param

Contains parameters (if any) accompanying the event.

int result

Event result. 0 or a negative error code (errno.h) indicating reason of failure.

struct mqtt\_sec\_config

*#include <mqtt.h>* TLS configuration for secure MQTT transports.

### Public Members

int peer\_verify

Indicates the preference for peer verification.

uint32\_t cipher\_count

Indicates the number of entries in the cipher list.

int \*cipher\_list

Indicates the list of ciphers to be used for the session. May be NULL to use the default ciphers.

uint32\_t sec\_tag\_count

Indicates the number of entries in the sec tag list.

*sec\_tag\_t* \*sec\_tag\_list

Indicates the list of security tags to be used for the session.

```
const char *hostname
```

Peer hostname for certificate verification. May be NULL to skip hostname verification.

```
struct mqtt_transport
```

*#include <mqtt.h>* MQTT transport specific data.

### Public Members

```
enum mqtt_transport_type type
```

Transport type selection for client instance. *mqtt\_transport\_type* for possible values. MQTT\_TRANSPORT\_MAX is not a valid type.

```
int sock
```

Socket descriptor.

```
struct mqtt_internal
```

*#include <mqtt.h>* MQTT internal state.

### Public Members

```
struct sys_mutex mutex
```

Internal. Mutex to protect access to the client instance.

```
uint32_t last_activity
```

Internal. Wall clock value (in milliseconds) of the last activity that occurred. Needed for periodic PING.

```
uint32_t state
```

Internal. Client's state in the connection.

```
uint32_t rx_buf_data_len
```

Internal. Packet length read so far.

```
uint32_t remaining_payload
```

Internal. Remaining payload length to read.

```
struct mqtt_client
```

*#include <mqtt.h>* MQTT Client definition to maintain information relevant to the client.

### Public Members

```
struct mqtt_internal internal
```

MQTT client internal state.

```
struct mqtt_transport transport
```

MQTT transport configuration and data.

struct *mqtt\_utf8* client\_id

Unique client identification to be used for the connection.

const void \*broker

Broker details, for example, address, port. Address type should be compatible with transport used.

struct *mqtt\_utf8* \*user\_name

User name (if any) to be used for the connection. NULL indicates no user name.

struct *mqtt\_utf8* \*password

Password (if any) to be used for the connection. Note that if password is provided, user name shall also be provided. NULL indicates no password.

struct *mqtt\_topic* \*will\_topic

Will topic and QoS. Can be NULL.

struct *mqtt\_utf8* \*will\_message

Will message. Can be NULL. Non NULL value valid only if will topic is not NULL.

*mqtt\_evt\_cb\_t* evt\_cb

Application callback registered with the module to get MQTT events.

uint8\_t \*rx\_buf

Receive buffer used for MQTT packet reception in RX path.

uint32\_t rx\_buf\_size

Size of receive buffer.

uint8\_t \*tx\_buf

Transmit buffer used for creating MQTT packet in TX path.

uint32\_t tx\_buf\_size

Size of transmit buffer.

uint16\_t keepalive

Keepalive interval for this client in seconds. Default is CONFIG\_MQTT\_KEEPAIVE.

uint8\_t protocol\_version

MQTT protocol version.

int8\_t unacked\_ping

Unanswered PINGREQ count on this connection.

uint8\_t will\_retain

Will retain flag, 1 if will message shall be retained persistently.

uint8\_t clean\_session

Clean session flag indicating a fresh (1) or a retained session (0). Default is CONFIG\_MQTT\_CLEAN\_SESSION.

## 7.20.5 Network System Management

### Network Configuration Library

- [Overview](#)
- [Sample usage](#)
- [API Reference](#)

**Overview** The network configuration library sets up networking devices in a semi-automatic way during the system boot, based on user-supplied Kconfig options.

The following Kconfig options affect how configuration library will setup the system:

Table 5: Kconfig options for network configuration library

Option name	Description
<b>:kconfig: `CONFIG_NET_CONFIG_LIB`</b>	This option controls whether the network system is configured or initialized at all. If not set, then the configuration library is not used for initialization and the application needs to do all the network related configuration itself. If this option is set, then the user can optionally configure static IP addresses to be set to the first network interface in the system. Typically setting static IP addresses is only usable in testing and should not be used in production code. See the config library Kconfig file <code>subsys/net/lib/config/Kconfig</code> for specific options to set the static IP addresses.
<b>:kconfig: `CONFIG_NET_CONFIG_AUTO_INIT`</b>	The networking system is automatically configured when the device is started.
<b>:kconfig: `CONFIG_NET_CONFIG_TIMEOUT`</b>	This tells how long to wait for the networking to be ready and available. If for example IPv4 address from DHCP is not received within this limit, then a call to <code>net_config_init()</code> will return error during the device startup.
<b>:kconfig: `CONFIG_NET_CONFIG_IPV4`</b>	The network application needs IPv4 support to function properly. This option makes sure the network application is initialized properly in order to use IPv4. If <b>:kconfig: `CONFIG_NET_IPV4`</b> is not enabled, then setting this option will automatically enable IPv4.
<b>:kconfig: `CONFIG_NET_CONFIG_IPV6`</b>	The network application needs IPv6 support to function properly. This option makes sure the network application is initialized properly in order to use IPv6. If <b>:kconfig: `CONFIG_NET_IPV6`</b> is not enabled, then setting this option will automatically enable IPv6.
<b>:kconfig: `CONFIG_NET_CONFIG_IPV6_ROUTER`</b>	If IPv6 is enabled, then this option tells that the network application needs IPv6 router to exist before continuing. IPv6 means in practice that the application wants to wait until it receives IPv6 router advertisement message before continuing.
<b>:kconfig: `CONFIG_NET_CONFIG_BT`</b>	Enables application to operate in Bluetooth node mode which requires GATT service to be registered and start advertising as peripheral.

**Sample usage** If **:kconfig: `CONFIG\_NET\_CONFIG\_AUTO\_INIT`** is set, then the configuration library is automatically enabled and run during the device boot. In this case, the library will call `net_config_init()` automatically and the application does not need to do any network configuration.

If you want to use the network configuration library but without automatic initialization, you can call `net_config_init()` manually. The `flags` parameter can be used to give hints to the library about what kind of functionality the application wishes to have before the actual application starts.

### API Reference

group `net_config`

Network configuration library.

## Defines

`NET_CONFIG_NEED_ROUTER`

Application needs routers to be set so that connectivity to remote network is possible. For IPv6 networks, this means that the device should receive IPv6 router advertisement message before continuing.

`NET_CONFIG_NEED_IPV6`

Application needs IPv6 subsystem configured and initialized. Typically this means that the device has IPv6 address set.

`NET_CONFIG_NEED_IPV4`

Application needs IPv4 subsystem configured and initialized. Typically this means that the device has IPv4 address set.

## Functions

`int net_config_init(const char *app_info, uint32_t flags, int32_t timeout)`

Initialize this network application.

This will call [`net\_config\_init\_by\_iface\(\)`](#) with NULL network interface.

### Parameters

- `app_info` – String describing this application.
- `flags` – Flags related to services needed by the client.
- `timeout` – How long to wait the network setup before continuing the startup.

**Returns** 0 if ok, <0 if error.

`int net_config_init_by_iface(struct net\_if *iface, const char *app_info, uint32_t flags, int32_t timeout)`

Initialize this network application using a specific network interface.

If network interface is set to NULL, then the default one is used in the configuration.

### Parameters

- `iface` – Initialize networking using this network interface.
- `app_info` – String describing this application.
- `flags` – Flags related to services needed by the client.
- `timeout` – How long to wait the network setup before continuing the startup.

**Returns** 0 if ok, <0 if error.

`int net_config_init_app(const struct device *dev, const char *app_info)`

Initialize this network application.

If `CONFIG_NET_CONFIG_AUTO_INIT` is set, then this function is called automatically when the device boots. If that is not desired, unset the config option and call the function manually when the application starts.

### Parameters

- `dev` – Network device to use. The function will figure out what network interface to use based on the device. If the device is `NULL`, then default network interface is used by the function.
- `app_info` – String describing this application.

**Returns** 0 if ok, <0 if error.

## DHCPv4

- [Overview](#)
- [Sample usage](#)
- [API Reference](#)

**Overview** The Dynamic Host Configuration Protocol (DHCP) is a network management protocol used on IPv4 networks. A DHCPv4 server dynamically assigns an IPv4 address and other network configuration parameters to each device on a network so they can communicate with other IP networks. See this [DHCP Wikipedia article](#) for a detailed overview of how DHCP works.

Note that Zephyr only supports DHCP client functionality.

**Sample usage** See `dhcpv4-client-sample` for details.

## API Reference

*group* dhcpv4  
DHCPv4.

### Functions

`void net_dhcpv4_start(struct net\_if *iface)`

Start DHCPv4 client on an iface.

Start DHCPv4 client on a given interface. DHCPv4 client will start negotiation for IPv4 address. Once the negotiation is success IPv4 address details will be added to interface.

#### Parameters

- `iface` – A valid pointer on an interface

`void net_dhcpv4_stop(struct net\_if *iface)`

Stop DHCPv4 client on an iface.

Stop DHCPv4 client on a given interface. DHCPv4 client will remove all configuration obtained from a DHCP server from the interface and stop any further negotiation with the server.

#### Parameters

- `iface` – A valid pointer on an interface

## Hostname Configuration

- [Overview](#)
- [API Reference](#)

**Overview** A networked device might need a hostname, for example, if the device is configured to be a mDNS responder (see [DNS Resolve](#) for details) and needs to respond to <hostname>.local DNS queries.

The `:kconfig: CONFIG_NET_HOSTNAME_ENABLE` must be set in order to store the hostname and enable the relevant APIs. If the option is enabled, then the default hostname is set to be zephyr by `:kconfig: CONFIG_NET_HOSTNAME` option.

If the same firmware image is used to flash multiple boards, then it is not practical to use the same hostname in all of the boards. In that case, one can enable `:kconfig: CONFIG_NET_HOSTNAME_UNIQUE` which will add a unique postfix to the hostname. By default the link local address of the first network interface is used as a postfix. In Ethernet networks, the link local address refers to MAC address. For example, if the link local address is 01:02:03:04:05:06, then the unique hostname could be zephyr010203040506. If you want to set the prefix yourself, then call `net_hostname_set_postfix()` before the network interfaces are created. For example for the Ethernet networks, the initialization priority is set by `:kconfig: CONFIG_ETH_INIT_PRIORITY` so you would need to set the postfix before that. The postfix can be set only once.

## API Reference

*group* `net_hostname`

Network hostname configuration library.

### Defines

`NET_HOSTNAME_MAX_LEN`

### Functions

`static inline const char *net_hostname_get(void)`

Get the device hostname.

Return pointer to device hostname.

**Returns** Pointer to hostname or NULL if not set.

`static inline void net_hostname_init(void)`

Initialize and set the device hostname.

`static inline int net_hostname_set_postfix(const uint8_t *hostname_postfix, int postfix_len)`

Set the device hostname postfix.

Set the device hostname to some value. This is only used if `CONFIG_NET_HOSTNAME_UNIQUE` is set.

#### Parameters

- `hostname_postfix` – Usually link address. The function will convert this to a string.
- `postfix_len` – Length of the `hostname_postfix` array.

**Returns** 0 if ok, <0 if error

## Network Core Helpers

- [Overview](#)
- [API Reference](#)

**Overview** The network subsystem contains two functions for sending and receiving data from the network. The `net_recv_data()` is typically used by network device driver when the received network data needs to be pushed up in the network stack for further processing. All the data is received via a network interface which is typically created by the device driver.

For sending, the `net_send_data()` can be used. Typically applications do not call this function directly as there is the [BSD Sockets](#) API for sending and receiving network data.

## API Reference

group `net_core`

Network core library.

### Enums

enum `net_verdict`

Net Verdict.

*Values:*

enumerator `NET_OK`

Packet has been taken care of.

enumerator `NET_CONTINUE`

Packet has not been touched, other part should decide about its fate.

enumerator `NET_DROP`

Packet must be dropped.

### Functions

int `net_recv_data`(struct [net\\_if](#) \*iface, struct [net\\_pkt](#) \*pkt)

Called by lower network stack or network device driver when a network packet has been received. The function will push the packet up in the network stack for further processing.

#### Parameters

- `iface` – Network interface where the packet was received.
- `pkt` – Network packet data.

**Returns** 0 if ok, <0 if error.

```
int net_send_data(struct net_pkt *pkt)
```

Send data to network.

Send data to network. This should not be used normally by applications as it requires that the network packet is properly constructed.

#### Parameters

- pkt – Network packet.

**Returns** 0 if ok, <0 if error. If <0 is returned, then the caller needs to unref the pkt in order to avoid memory leak.

## Network Interface

- [Overview](#)
- [API Reference](#)

**Overview** The network interface is a nexus that ties the network device drivers and the upper part of the network stack together. All the sent and received data is transferred via a network interface. The network interfaces cannot be created at runtime. A special linker section will contain information about them and that section is populated at linking time.

Network interfaces are created by `NET_DEVICE_INIT()` macro. For Ethernet network, a macro called `ETH_NET_DEVICE_INIT()` should be used instead as it will create VLAN interfaces automatically if **:kconfig: `CONFIG\_NET\_VLAN`** is enabled. These macros are typically used in network device driver source code.

The network interface can be turned ON by calling `net_if_up()` and OFF by calling `net_if_down()`. When the device is powered ON, the network interface is also turned ON by default.

The network interfaces can be referenced either by a `struct net_if *` pointer or by a network interface index. The network interface can be resolved from its index by calling `net_if_get_by_index()` and from interface pointer by calling `net_if_get_by_iface()`.

The IP address for network devices must be set for them to be connectable. In a typical dynamic network environment, IP addresses are set automatically by DHCPv4, for example. If needed though, the application can set a device's IP address manually. See the API documentation below for functions such as `net_if_ipv4_addr_add()` that do that.

The `net_if_get_default()` returns a *default* network interface. What this default interface means can be configured via options like **:kconfig: `CONFIG\_NET\_DEFAULT\_IF\_FIRST`** and **:kconfig: `CONFIG\_NET\_DEFAULT\_IF\_ETHERNET`**. See Kconfig file `subsys/net/ip/Kconfig` what options are available for selecting the default network interface.

The transmitted and received network packets can be classified via a network packet priority. This is typically done in Ethernet networks when virtual LANs (VLANs) are used. Higher priority packets can be sent or received earlier than lower priority packets. The traffic class setup can be configured by **:kconfig: `CONFIG\_NET\_TC\_TX\_COUNT`** and **:kconfig: `CONFIG\_NET\_TC\_RX\_COUNT`** options.

If the **:kconfig: `CONFIG\_NET\_PROMISCUOUS\_MODE`** is enabled and if the underlying network technology supports promiscuous mode, then it is possible to receive all the network packets that the network device driver is able to receive. See [Promiscuous Mode](#) API for more details.

## API Reference

*group* `net_if`

Network Interface abstraction layer.

## Defines

`NET_DEVICE_INIT(dev_name, drv_name, init_fn, pm_control_fn, data, cfg, prio, api, l2, l2_ctx_type, mtu)`

Create a network interface and bind it to network device.

### Parameters

- `dev_name` – Network device name.
- `drv_name` – The name this instance of the driver exposes to the system.
- `init_fn` – Address to the init function of the driver.
- `pm_control_fn` – Pointer to `pm_control` function. Can be NULL if not implemented.
- `data` – Pointer to the device's private data.
- `cfg` – The address to the structure containing the configuration information for this instance of the driver.
- `prio` – The initialization level at which configuration occurs.
- `api` – Provides an initial pointer to the API function struct used by the driver. Can be NULL.
- `l2` – Network L2 layer for this network interface.
- `l2_ctx_type` – Type of L2 context data.
- `mtu` – Maximum transfer unit in bytes for this network interface.

`NET_DEVICE_DT_DEFINE(node_id, init_fn, pm_control_fn, data, cfg, prio, api, l2, l2_ctx_type, mtu)`

Like `NET_DEVICE_INIT` but taking metadata from a devicetree node. Create a network interface and bind it to network device.

### Parameters

- `node_id` – The devicetree node identifier.
- `init_fn` – Address to the init function of the driver.
- `pm_control_fn` – Pointer to `pm_control` function. Can be NULL if not implemented.
- `data` – Pointer to the device's private data.
- `cfg` – The address to the structure containing the configuration information for this instance of the driver.
- `prio` – The initialization level at which configuration occurs.
- `api` – Provides an initial pointer to the API function struct used by the driver. Can be NULL.
- `l2` – Network L2 layer for this network interface.
- `l2_ctx_type` – Type of L2 context data.
- `mtu` – Maximum transfer unit in bytes for this network interface.

`NET_DEVICE_DT_INST_DEFINE(inst, ...)`

Like `NET_DEVICE_DT_DEFINE` for an instance of a `DT_DRV_COMPAT` compatible.

### Parameters

- `inst` – instance number. This is replaced by `DT_DRV_COMPAT(inst)` in the call to `NET_DEVICE_DT_DEFINE`.

- ... – other parameters as expected by NET\_DEVICE\_DT\_DEFINE.

NET\_DEVICE\_INIT\_INSTANCE(dev\_name, drv\_name, instance, init\_fn, pm\_control\_fn, data, cfg, prio, api, l2, l2\_ctx\_type, mtu)

Create multiple network interfaces and bind them to network device. If your network device needs more than one instance of a network interface, use this macro below and provide a different instance suffix each time (0, 1, 2, ... or a, b, c ... whatever works for you)

#### Parameters

- dev\_name – Network device name.
- drv\_name – The name this instance of the driver exposes to the system.
- instance – Instance identifier.
- init\_fn – Address to the init function of the driver.
- pm\_control\_fn – Pointer to pm\_control function. Can be NULL if not implemented.
- data – Pointer to the device's private data.
- cfg – The address to the structure containing the configuration information for this instance of the driver.
- prio – The initialization level at which configuration occurs.
- api – Provides an initial pointer to the API function struct used by the driver. Can be NULL.
- l2 – Network L2 layer for this network interface.
- l2\_ctx\_type – Type of L2 context data.
- mtu – Maximum transfer unit in bytes for this network interface.

NET\_DEVICE\_DT\_DEFINE\_INSTANCE(node\_id, instance, init\_fn, pm\_control\_fn, data, cfg, prio, api, l2, l2\_ctx\_type, mtu)

Like NET\_DEVICE\_OFFLOAD\_INIT but taking metadata from a devicetree. Create multiple network interfaces and bind them to network device. If your network device needs more than one instance of a network interface, use this macro below and provide a different instance suffix each time (0, 1, 2, ... or a, b, c ... whatever works for you)

#### Parameters

- node\_id – The devicetree node identifier.
- instance – Instance identifier.
- init\_fn – Address to the init function of the driver.
- pm\_control\_fn – Pointer to pm\_control function. Can be NULL if not implemented.
- data – Pointer to the device's private data.
- cfg – The address to the structure containing the configuration information for this instance of the driver.
- prio – The initialization level at which configuration occurs.
- api – Provides an initial pointer to the API function struct used by the driver. Can be NULL.
- l2 – Network L2 layer for this network interface.
- l2\_ctx\_type – Type of L2 context data.
- mtu – Maximum transfer unit in bytes for this network interface.

`NET_DEVICE_DT_INST_DEFINE_INSTANCE(inst, ...)`

Like `NET_DEVICE_DT_DEFINE_INSTANCE` for an instance of a `DT_DRV_COMPAT` compatible.

#### Parameters

- `inst` – instance number. This is replaced by `DT_DRV_COMPAT(inst)` in the call to `NET_DEVICE_DT_DEFINE_INSTANCE`.
- `...` – other parameters as expected by `NET_DEVICE_DT_DEFINE_INSTANCE`.

`NET_DEVICE_OFFLOAD_INIT(dev_name, drv_name, init_fn, pm_control_fn, data, cfg, prio, api, mtu)`

Create a offloaded network interface and bind it to network device. The offloaded network interface is implemented by a device vendor HAL or similar.

#### Parameters

- `dev_name` – Network device name.
- `drv_name` – The name this instance of the driver exposes to the system.
- `init_fn` – Address to the init function of the driver.
- `pm_control_fn` – Pointer to `pm_control` function. Can be NULL if not implemented.
- `data` – Pointer to the device's private data.
- `cfg` – The address to the structure containing the configuration information for this instance of the driver.
- `prio` – The initialization level at which configuration occurs.
- `api` – Provides an initial pointer to the API function struct used by the driver. Can be NULL.
- `mtu` – Maximum transfer unit in bytes for this network interface.

`NET_DEVICE_DT_OFFLOAD_DEFINE(node_id, init_fn, pm_control_fn, data, cfg, prio, api, mtu)`

Like `NET_DEVICE_OFFLOAD_INIT` but taking metadata from a devicetree node. Create a offloaded network interface and bind it to network device. The offloaded network interface is implemented by a device vendor HAL or similar.

#### Parameters

- `node_id` – The devicetree node identifier.
- `init_fn` – Address to the init function of the driver.
- `pm_control_fn` – Pointer to `pm_control` function. Can be NULL if not implemented.
- `data` – Pointer to the device's private data.
- `cfg` – The address to the structure containing the configuration information for this instance of the driver.
- `prio` – The initialization level at which configuration occurs.
- `api` – Provides an initial pointer to the API function struct used by the driver. Can be NULL.
- `mtu` – Maximum transfer unit in bytes for this network interface.

`NET_DEVICE_DT_INST_OFFLOAD_DEFINE(inst, ...)`

Like `NET_DEVICE_DT_OFFLOAD_DEFINE` for an instance of a `DT_DRV_COMPAT` compatible.

#### Parameters

- `inst` – instance number. This is replaced by `DT_DRV_COMPAT(inst)` in the call to `NET_DEVICE_DT_OFFLOAD_DEFINE`.

- ... – other parameters as expected by `NET_DEVICE_DT_OFFLOAD_DEFINE`.

## Typedefs

```
typedef void (*net_if_mcast_callback_t)(struct net_if *iface, const struct in6_addr *addr, bool is_joined)
```

Define callback that is called whenever IPv6 multicast address group is joined or left.

**Param iface** A pointer to a struct `net_if` to which the multicast address is attached.

**Param addr** IPv6 multicast address.

**Param is\_joined** True if the address is joined, false if left.

```
typedef void (*net_if_link_callback_t)(struct net_if *iface, struct net_linkaddr *dst, int status)
```

Define callback that is called after a network packet has been sent.

**Param iface** A pointer to a struct `net_if` to which the the `net_pkt` was sent to.

**Param dst** Link layer address of the destination where the network packet was sent.

**Param status** Send status, 0 is ok, < 0 error.

```
typedef void (*net_if_cb_t)(struct net_if *iface, void *user_data)
```

Callback used while iterating over network interfaces.

**Param iface** Pointer to current network interface

**Param user\_data** A valid pointer to user data or NULL

## Enums

```
enum net_if_flag
```

*Values:*

```
enumerator NET_IF_UP
```

Interface is up/ready to receive and transmit

```
enumerator NET_IF_POINTOPOINT
```

Interface is pointopoint

```
enumerator NET_IF_PROMISC
```

Interface is in promiscuous mode

```
enumerator NET_IF_NO_AUTO_START
```

Do not start the interface immediately after initialization. This requires that either the device driver or some other entity will need to manually take the interface up when needed. For example for Ethernet this will happen when the driver calls the `net_eth_carrier_on()` function.

```
enumerator NET_IF_SUSPENDED
```

Power management specific: interface is being suspended

enumerator NET\_IF\_FORWARD\_MULTICASTS

Flag defines if received multicasts of other interface are forwarded on this interface. This activates multicast routing / forwarding for this interface.

enumerator NET\_IF\_IPV4

Interface supports IPv4

enumerator NET\_IF\_IPV6

Interface supports IPv6

## Functions

static inline void net\_if\_flag\_set(struct *net\_if* \*iface, enum *net\_if\_flag* value)

Set a value in network interface flags.

### Parameters

- *iface* – Pointer to network interface
- *value* – Flag value

static inline bool net\_if\_flag\_test\_and\_set(struct *net\_if* \*iface, enum *net\_if\_flag* value)

Test and set a value in network interface flags.

### Parameters

- *iface* – Pointer to network interface
- *value* – Flag value

**Returns** true if the bit was set, false if it wasn't.

static inline void net\_if\_flag\_clear(struct *net\_if* \*iface, enum *net\_if\_flag* value)

Clear a value in network interface flags.

### Parameters

- *iface* – Pointer to network interface
- *value* – Flag value

static inline bool net\_if\_flag\_is\_set(struct *net\_if* \*iface, enum *net\_if\_flag* value)

Check if a value in network interface flags is set.

### Parameters

- *iface* – Pointer to network interface
- *value* – Flag value

**Returns** True if the value is set, false otherwise

enum *net\_verdict* net\_if\_send\_data(struct *net\_if* \*iface, struct *net\_pkt* \*pkt)

Send a packet through a net iface.

return verdict about the packet

### Parameters

- *iface* – Pointer to a network interface structure
- *pkt* – Pointer to a net packet to send

static inline const struct [net\\_l2](#) \*const net\_if\_l2(struct [net\\_if](#) \*iface)

Get a pointer to the interface L2.

**Parameters**

- `iface` – a valid pointer to a network interface structure

**Returns** a pointer to the iface L2

enum [net\\_verdict](#) net\_if\_recv\_data(struct [net\\_if](#) \*iface, struct [net\\_pkt](#) \*pkt)

Input a packet through a net iface.

**Parameters**

- `iface` – Pointer to a network interface structure
- `pkt` – Pointer to a net packet to input

**Returns** verdict about the packet

static inline void \*net\_if\_l2\_data(struct [net\\_if](#) \*iface)

Get a pointer to the interface L2 private data.

**Parameters**

- `iface` – a valid pointer to a network interface structure

**Returns** a pointer to the iface L2 data

static inline const struct [device](#) \*net\_if\_get\_device(struct [net\\_if](#) \*iface)

Get an network interface's device.

**Parameters**

- `iface` – Pointer to a network interface structure

**Returns** a pointer to the device driver instance

void net\_if\_queue\_tx(struct [net\\_if](#) \*iface, struct [net\\_pkt](#) \*pkt)

Queue a packet to the net interface TX queue.

**Parameters**

- `iface` – Pointer to a network interface structure
- `pkt` – Pointer to a net packet to queue

static inline bool net\_if\_is\_ip\_offloaded(struct [net\\_if](#) \*iface)

Return the IP offload status.

**Parameters**

- `iface` – Network interface

**Returns** True if IP offloading is active, false otherwise.

static inline struct net\_offload \*net\_if\_offload(struct [net\\_if](#) \*iface)

Return the IP offload plugin.

**Parameters**

- `iface` – Network interface

**Returns** NULL if there is no offload plugin defined, valid pointer otherwise

static inline bool net\_if\_is\_socket\_offloaded(struct [net\\_if](#) \*iface)

Return the socket offload status.

**Parameters**

- `iface` – Network interface

**Returns** True if socket offloading is active, false otherwise.

```
static inline struct net_linkaddr *net_if_get_link_addr(struct net_if *iface)
```

Get an network interface's link address.

**Parameters**

- *iface* – Pointer to a network interface structure

**Returns** a pointer to the network link address

```
static inline struct net_if_config *net_if_get_config(struct net_if *iface)
```

Return network configuration for this network interface.

**Parameters**

- *iface* – Pointer to a network interface structure

**Returns** Pointer to configuration

```
static inline void net_if_start_dad(struct net_if *iface)
```

Start duplicate address detection procedure.

**Parameters**

- *iface* – Pointer to a network interface structure

```
void net_if_start_rs(struct net_if *iface)
```

Start neighbor discovery and send router solicitation message.

**Parameters**

- *iface* – Pointer to a network interface structure

```
static inline void net_if_stop_rs(struct net_if *iface)
```

Stop neighbor discovery.

**Parameters**

- *iface* – Pointer to a network interface structure

```
static inline int net_if_set_link_addr(struct net_if *iface, uint8_t *addr, uint8_t len, enum  
net_link_type type)
```

Set a network interface's link address.

**Parameters**

- *iface* – Pointer to a network interface structure
- *addr* – A pointer to a `uint8_t` buffer representing the address. The buffer must remain valid throughout interface lifetime.
- *len* – length of the address buffer
- *type* – network bearer type of this link address

**Returns** 0 on success

```
static inline uint16_t net_if_get_mtu(struct net_if *iface)
```

Get an network interface's MTU.

**Parameters**

- *iface* – Pointer to a network interface structure

**Returns** the MTU

```
static inline void net_if_set_mtu(struct net\_if *iface, uint16_t mtu)
```

Set an network interface's MTU.

**Parameters**

- `iface` – Pointer to a network interface structure
- `mtu` – New MTU, note that we store only 16 bit mtu value.

```
static inline void net_if_addr_set_1f(struct net\_if\_addr *ifaddr, bool is_infinite)
```

Set the infinite status of the network interface address.

**Parameters**

- `ifaddr` – IP address for network interface
- `is_infinite` – Infinite status

```
struct net\_if *net_if_get_by_link_addr(struct net\_linkaddr *ll_addr)
```

Get an interface according to link layer address.

**Parameters**

- `ll_addr` – Link layer address.

**Returns** Network interface or NULL if not found.

```
struct net\_if *net_if_lookup_by_dev(const struct device *dev)
```

Find an interface from it's related device.

**Parameters**

- `dev` – A valid struct device pointer to relate with an interface

**Returns** a valid struct [net\\_if](#) pointer on success, NULL otherwise

```
static inline struct net\_if\_config *net_if_config_get(struct net\_if *iface)
```

Get network interface IP config.

**Parameters**

- `iface` – Interface to use.

**Returns** NULL if not found or pointer to correct config settings.

```
void net_if_router_rm(struct net\_if\_router *router)
```

Remove a router from the system.

**Parameters**

- `router` – Pointer to existing router

```
struct net\_if *net_if_get_default(void)
```

Get the default network interface.

**Returns** Default interface or NULL if no interfaces are configured.

```
struct net\_if *net_if_get_first_by_type(const struct net\_l2 *l2)
```

Get the first network interface according to its type.

**Parameters**

- `l2` – Layer 2 type of the network interface.

**Returns** First network interface of a given type or NULL if no such interfaces was found.

```
int net_if_config_ipv6_get(struct net_if *iface, struct net_if_ipv6 **ipv6)
```

Allocate network interface IPv6 config.

This function will allocate new IPv6 config.

**Parameters**

- *iface* – Interface to use.
- *ipv6* – Pointer to allocated IPv6 struct is returned to caller.

**Returns** 0 if ok, <0 if error

```
int net_if_config_ipv6_put(struct net_if *iface)
```

Release network interface IPv6 config.

**Parameters**

- *iface* – Interface to use.

**Returns** 0 if ok, <0 if error

```
struct net_if_addr *net_if_ipv6_addr_lookup(const struct in6_addr *addr, struct net_if **iface)
```

Check if this IPv6 address belongs to one of the interfaces.

**Parameters**

- *addr* – IPv6 address
- *iface* – Pointer to interface is returned

**Returns** Pointer to interface address, NULL if not found.

```
struct net_if_addr *net_if_ipv6_addr_lookup_by_iface(struct net_if *iface, struct in6_addr *addr)
```

Check if this IPv6 address belongs to this specific interfaces.

**Parameters**

- *iface* – Network interface
- *addr* – IPv6 address

**Returns** Pointer to interface address, NULL if not found.

```
int net_if_ipv6_addr_lookup_by_index(const struct in6_addr *addr)
```

Check if this IPv6 address belongs to one of the interface indices.

**Parameters**

- *addr* – IPv6 address

**Returns** >0 if address was found in given network interface index, all other values mean address was not found

```
struct net_if_addr *net_if_ipv6_addr_add(struct net_if *iface, struct in6_addr *addr, enum net_addr_type addr_type, uint32_t vlifetime)
```

Add a IPv6 address to an interface.

**Parameters**

- *iface* – Network interface
- *addr* – IPv6 address
- *addr\_type* – IPv6 address type
- *vlifetime* – Validity time for this address

**Returns** Pointer to interface address, NULL if cannot be added

```
bool net_if_ipv6_addr_add_by_index(int index, struct in6_addr *addr, enum net_addr_type
                                addr_type, uint32_t vlifetime)
```

Add a IPv6 address to an interface by index.

**Parameters**

- `index` – Network interface index
- `addr` – IPv6 address
- `addr_type` – IPv6 address type
- `vlifetime` – Validity time for this address

**Returns** True if ok, false if address could not be added

```
void net_if_ipv6_addr_update_lifetime(struct net_if_addr *ifaddr, uint32_t vlifetime)
```

Update validity lifetime time of an IPv6 address.

**Parameters**

- `ifaddr` – Network IPv6 address
- `vlifetime` – Validity time for this address

```
bool net_if_ipv6_addr_rm(struct net_if *iface, const struct in6_addr *addr)
```

Remove an IPv6 address from an interface.

**Parameters**

- `iface` – Network interface
- `addr` – IPv6 address

**Returns** True if successfully removed, false otherwise

```
bool net_if_ipv6_addr_rm_by_index(int index, const struct in6_addr *addr)
```

Remove an IPv6 address from an interface by index.

**Parameters**

- `index` – Network interface index
- `addr` – IPv6 address

**Returns** True if successfully removed, false otherwise

```
struct net_if_mcast_addr *net_if_ipv6_maddr_add(struct net_if *iface, const struct in6_addr
                                                *addr)
```

Add a IPv6 multicast address to an interface.

**Parameters**

- `iface` – Network interface
- `addr` – IPv6 multicast address

**Returns** Pointer to interface multicast address, NULL if cannot be added

```
bool net_if_ipv6_maddr_rm(struct net_if *iface, const struct in6_addr *addr)
```

Remove an IPv6 multicast address from an interface.

**Parameters**

- `iface` – Network interface
- `addr` – IPv6 multicast address

**Returns** True if successfully removed, false otherwise

```
struct net_if_mcast_addr *net_if_ipv6_maddr_lookup(const struct in6_addr *addr, struct net_if
                                                    **iface)
```

Check if this IPv6 multicast address belongs to a specific interface or one of the interfaces.

#### Parameters

- *addr* – IPv6 address
- *iface* – If *\*iface* is null, then pointer to interface is returned, otherwise the *\*iface* value needs to be matched.

**Returns** Pointer to interface multicast address, NULL if not found.

```
void net_if_mcast_mon_register(struct net_if_mcast_monitor *mon, struct net_if *iface,
                               net_if_mcast_callback_t cb)
```

Register a multicast monitor.

#### Parameters

- *mon* – Monitor handle. This is a pointer to a monitor storage structure which should be allocated by caller, but does not need to be initialized.
- *iface* – Network interface
- *cb* – Monitor callback

```
void net_if_mcast_mon_unregister(struct net_if_mcast_monitor *mon)
```

Unregister a multicast monitor.

#### Parameters

- *mon* – Monitor handle

```
void net_if_mcast_monitor(struct net_if *iface, const struct in6_addr *addr, bool is_joined)
```

Call registered multicast monitors.

#### Parameters

- *iface* – Network interface
- *addr* – Multicast address
- *is\_joined* – Is this multicast address joined (true) or not (false)

```
void net_if_ipv6_maddr_join(struct net_if_mcast_addr *addr)
```

Mark a given multicast address to be joined.

#### Parameters

- *addr* – IPv6 multicast address

```
static inline bool net_if_ipv6_maddr_is_joined(struct net_if_mcast_addr *addr)
```

Check if given multicast address is joined or not.

#### Parameters

- *addr* – IPv6 multicast address

**Returns** True if address is joined, False otherwise.

```
void net_if_ipv6_maddr_leave(struct net_if_mcast_addr *addr)
```

Mark a given multicast address to be left.

#### Parameters

- *addr* – IPv6 multicast address

```
struct net_if_ipv6_prefix *net_if_ipv6_prefix_get(struct net_if *iface, struct in6_addr *addr)
```

Return prefix that corresponds to this IPv6 address.

**Parameters**

- *iface* – Network interface
- *addr* – IPv6 address

**Returns** Pointer to prefix, NULL if not found.

```
struct net_if_ipv6_prefix *net_if_ipv6_prefix_lookup(struct net_if *iface, struct in6_addr *addr, uint8_t len)
```

Check if this IPv6 prefix belongs to this interface.

**Parameters**

- *iface* – Network interface
- *addr* – IPv6 address
- *len* – Prefix length

**Returns** Pointer to prefix, NULL if not found.

```
struct net_if_ipv6_prefix *net_if_ipv6_prefix_add(struct net_if *iface, struct in6_addr *prefix, uint8_t len, uint32_t lifetime)
```

Add a IPv6 prefix to an network interface.

**Parameters**

- *iface* – Network interface
- *prefix* – IPv6 address
- *len* – Prefix length
- *lifetime* – Prefix lifetime in seconds

**Returns** Pointer to prefix, NULL if the prefix was not added.

```
bool net_if_ipv6_prefix_rm(struct net_if *iface, struct in6_addr *addr, uint8_t len)
```

Remove an IPv6 prefix from an interface.

**Parameters**

- *iface* – Network interface
- *addr* – IPv6 prefix address
- *len* – Prefix length

**Returns** True if successfully removed, false otherwise

```
static inline void net_if_ipv6_prefix_set_lf(struct net_if_ipv6_prefix *prefix, bool is_infinite)
```

Set the infinite status of the prefix.

**Parameters**

- *prefix* – IPv6 address
- *is\_infinite* – Infinite status

```
void net_if_ipv6_prefix_set_timer(struct net_if_ipv6_prefix *prefix, uint32_t lifetime)
```

Set the prefix lifetime timer.

**Parameters**

- *prefix* – IPv6 address
- *lifetime* – Prefix lifetime in seconds

```
void net_if_ipv6_prefix_unset_timer(struct net_if_ipv6_prefix *prefix)
```

Unset the prefix lifetime timer.

**Parameters**

- `prefix` – IPv6 address

```
bool net_if_ipv6_addr_onlink(struct net_if **iface, struct in6_addr *addr)
```

Check if this IPv6 address is part of the subnet of our network interface.

**Parameters**

- `iface` – Network interface. This is returned to the caller. The `iface` can be NULL in which case we check all the interfaces.
- `addr` – IPv6 address

**Returns** True if address is part of our subnet, false otherwise

```
static inline struct in6_addr *net_if_router_ipv6(struct net_if_router *router)
```

Get the IPv6 address of the given router.

**Parameters**

- `router` – a network router

**Returns** pointer to the IPv6 address, or NULL if none

```
struct net_if_router *net_if_ipv6_router_lookup(struct net_if *iface, struct in6_addr *addr)
```

Check if IPv6 address is one of the routers configured in the system.

**Parameters**

- `iface` – Network interface
- `addr` – IPv6 address

**Returns** Pointer to router information, NULL if cannot be found

```
struct net_if_router *net_if_ipv6_router_find_default(struct net_if *iface, struct in6_addr *addr)
```

Find default router for this IPv6 address.

**Parameters**

- `iface` – Network interface. This can be NULL in which case we go through all the network interfaces to find a suitable router.
- `addr` – IPv6 address

**Returns** Pointer to router information, NULL if cannot be found

```
void net_if_ipv6_router_update_lifetime(struct net_if_router *router, uint16_t lifetime)
```

Update validity lifetime time of a router.

**Parameters**

- `router` – Network IPv6 address
- `lifetime` – Lifetime of this router.

```
struct net_if_router *net_if_ipv6_router_add(struct net_if *iface, struct in6_addr *addr, uint16_t router_lifetime)
```

Add IPv6 router to the system.

**Parameters**

- `iface` – Network interface
- `addr` – IPv6 address

- `router_lifetime` – Lifetime of the router

**Returns** Pointer to router information, NULL if could not be added

`bool net_if_ipv6_router_rm(struct net\_if\_router *router)`

Remove IPv6 router from the system.

**Parameters**

- `router` – Router information.

**Returns** True if successfully removed, false otherwise

`uint8_t net_if_ipv6_get_hop_limit(struct net\_if *iface)`

Get IPv6 hop limit specified for a given interface. This is the default value but can be overridden by the user.

**Parameters**

- `iface` – Network interface

**Returns** Hop limit

`void net_if_ipv6_set_hop_limit(struct net\_if *iface, uint8_t hop_limit)`

Set the default IPv6 hop limit of a given interface.

**Parameters**

- `iface` – Network interface
- `hop_limit` – New hop limit

`static inline void net_if_ipv6_set_base_reachable_time(struct net\_if *iface, uint32_t reachable_time)`

Set IPv6 reachable time for a given interface.

**Parameters**

- `iface` – Network interface
- `reachable_time` – New reachable time

`static inline uint32_t net_if_ipv6_get_reachable_time(struct net\_if *iface)`

Get IPv6 reachable timeout specified for a given interface.

**Parameters**

- `iface` – Network interface

**Returns** Reachable timeout

`uint32_t net_if_ipv6_calc_reachable_time(struct net\_if\_ipv6 *ipv6)`

Calculate next reachable time value for IPv6 reachable time.

**Parameters**

- `ipv6` – IPv6 address configuration

**Returns** Reachable time

`static inline void net_if_ipv6_set_reachable_time(struct net\_if\_ipv6 *ipv6)`

Set IPv6 reachable time for a given interface. This requires that base reachable time is set for the interface.

**Parameters**

- `ipv6` – IPv6 address configuration

static inline void net\_if\_ipv6\_set\_retrans\_timer(struct *net\_if* \*iface, uint32\_t retrans\_timer)  
Set IPv6 retransmit timer for a given interface.

**Parameters**

- *iface* – Network interface
- *retrans\_timer* – New retransmit timer

static inline uint32\_t net\_if\_ipv6\_get\_retrans\_timer(struct *net\_if* \*iface)  
Get IPv6 retransmit timer specified for a given interface.

**Parameters**

- *iface* – Network interface

**Returns** Retransmit timer

static inline const struct *in6\_addr* \*net\_if\_ipv6\_select\_src\_addr(struct *net\_if* \*iface, const struct *in6\_addr* \*dst)

Get a IPv6 source address that should be used when sending network data to destination.

**Parameters**

- *iface* – Interface that was used when packet was received. If the interface is not known, then NULL can be given.
- *dst* – IPv6 destination address

**Returns** Pointer to IPv6 address to use, NULL if no IPv6 address could be found.

static inline struct *net\_if* \*net\_if\_ipv6\_select\_src\_iface(const struct *in6\_addr* \*dst)  
Get a network interface that should be used when sending IPv6 network data to destination.

**Parameters**

- *dst* – IPv6 destination address

**Returns** Pointer to network interface to use, NULL if no suitable interface could be found.

struct *in6\_addr* \*net\_if\_ipv6\_get\_ll(struct *net\_if* \*iface, enum *net\_addr\_state* addr\_state)  
Get a IPv6 link local address in a given state.

**Parameters**

- *iface* – Interface to use. Must be a valid pointer to an interface.
- *addr\_state* – IPv6 address state (preferred, tentative, deprecated)

**Returns** Pointer to link local IPv6 address, NULL if no proper IPv6 address could be found.

struct *in6\_addr* \*net\_if\_ipv6\_get\_ll\_addr(enum *net\_addr\_state* state, struct *net\_if* \*\*iface)  
Return link local IPv6 address from the first interface that has a link local address matching give state.

**Parameters**

- *state* – IPv6 address state (ANY, TENTATIVE, PREFERRED, DEPRECATED)
- *iface* – Pointer to interface is returned

**Returns** Pointer to IPv6 address, NULL if not found.

void net\_if\_ipv6\_dad\_failed(struct *net\_if* \*iface, const struct *in6\_addr* \*addr)  
Stop IPv6 Duplicate Address Detection (DAD) procedure if we find out that our IPv6 address is already in use.

**Parameters**

- `iface` – Interface where the DAD was running.
- `addr` – IPv6 address that failed DAD

struct [in6\\_addr](#) \*net\_if\_ipv6\_get\_global\_addr(enum [net\\_addr\\_state](#) state, struct [net\\_if](#) \*\*iface)

Return global IPv6 address from the first interface that has a global IPv6 address matching the given state.

#### Parameters

- `state` – IPv6 address state (ANY, TENTATIVE, PREFERRED, DEPRECATED)
- `iface` – Caller can give an interface to check. If `iface` is set to NULL, then all the interfaces are checked. Pointer to interface where the IPv6 address is defined is returned to the caller.

**Returns** Pointer to IPv6 address, NULL if not found.

int net\_if\_config\_ipv4\_get(struct [net\\_if](#) \*iface, struct [net\\_if\\_ipv4](#) \*\*ipv4)

Allocate network interface IPv4 config.

This function will allocate new IPv4 config.

#### Parameters

- `iface` – Interface to use.
- `ipv4` – Pointer to allocated IPv4 struct is returned to caller.

**Returns** 0 if ok, <0 if error

int net\_if\_config\_ipv4\_put(struct [net\\_if](#) \*iface)

Release network interface IPv4 config.

#### Parameters

- `iface` – Interface to use.

**Returns** 0 if ok, <0 if error

uint8\_t net\_if\_ipv4\_get\_ttl(struct [net\\_if](#) \*iface)

Get IPv4 time-to-live value specified for a given interface.

#### Parameters

- `iface` – Network interface

**Returns** Time-to-live

void net\_if\_ipv4\_set\_ttl(struct [net\\_if](#) \*iface, uint8\_t ttl)

Set IPv4 time-to-live value specified to a given interface.

#### Parameters

- `iface` – Network interface
- `ttl` – Time-to-live value

struct [net\\_if\\_addr](#) \*net\_if\_ipv4\_addr\_lookup(const struct [in\\_addr](#) \*addr, struct [net\\_if](#) \*\*iface)

Check if this IPv4 address belongs to one of the interfaces.

#### Parameters

- `addr` – IPv4 address
- `iface` – Interface is returned

**Returns** Pointer to interface address, NULL if not found.

```
struct net_if_addr *net_if_ipv4_addr_add(struct net_if *iface, struct in_addr *addr, enum  
                                         net_addr_type addr_type, uint32_t vlifetime)
```

Add a IPv4 address to an interface.

**Parameters**

- *iface* – Network interface
- *addr* – IPv4 address
- *addr\_type* – IPv4 address type
- *vlifetime* – Validity time for this address

**Returns** Pointer to interface address, NULL if cannot be added

```
bool net_if_ipv4_addr_rm(struct net_if *iface, const struct in_addr *addr)
```

Remove a IPv4 address from an interface.

**Parameters**

- *iface* – Network interface
- *addr* – IPv4 address

**Returns** True if successfully removed, false otherwise

```
int net_if_ipv4_addr_lookup_by_index(const struct in_addr *addr)
```

Check if this IPv4 address belongs to one of the interface indices.

**Parameters**

- *addr* – IPv4 address

**Returns** >0 if address was found in given network interface index, all other values mean address was not found

```
bool net_if_ipv4_addr_add_by_index(int index, struct in_addr *addr, enum net_addr_type  
                                   addr_type, uint32_t vlifetime)
```

Add a IPv4 address to an interface by network interface index.

**Parameters**

- *index* – Network interface index
- *addr* – IPv4 address
- *addr\_type* – IPv4 address type
- *vlifetime* – Validity time for this address

**Returns** True if ok, false if the address could not be added

```
bool net_if_ipv4_addr_rm_by_index(int index, const struct in_addr *addr)
```

Remove a IPv4 address from an interface by interface index.

**Parameters**

- *index* – Network interface index
- *addr* – IPv4 address

**Returns** True if successfully removed, false otherwise

```
struct net_if_mcast_addr *net_if_ipv4_maddr_add(struct net_if *iface, const struct in_addr  
                                                  *addr)
```

Add a IPv4 multicast address to an interface.

**Parameters**

- *iface* – Network interface

- `addr` – IPv4 multicast address

**Returns** Pointer to interface multicast address, NULL if cannot be added

`bool net_if_ipv4_maddr_rm(struct net\_if *iface, const struct in\_addr *addr)`

Remove an IPv4 multicast address from an interface.

**Parameters**

- `iface` – Network interface
- `addr` – IPv4 multicast address

**Returns** True if successfully removed, false otherwise

`struct net\_if\_mcast\_addr *net_if_ipv4_maddr_lookup(const struct in\_addr *addr, struct net\_if **iface)`

Check if this IPv4 multicast address belongs to a specific interface or one of the interfaces.

**Parameters**

- `addr` – IPv4 address
- `iface` – If `*iface` is null, then pointer to interface is returned, otherwise the `*iface` value needs to be matched.

**Returns** Pointer to interface multicast address, NULL if not found.

`void net_if_ipv4_maddr_join(struct net\_if\_mcast\_addr *addr)`

Mark a given multicast address to be joined.

**Parameters**

- `addr` – IPv4 multicast address

`static inline bool net_if_ipv4_maddr_is_joined(struct net\_if\_mcast\_addr *addr)`

Check if given multicast address is joined or not.

**Parameters**

- `addr` – IPv4 multicast address

**Returns** True if address is joined, False otherwise.

`void net_if_ipv4_maddr_leave(struct net\_if\_mcast\_addr *addr)`

Mark a given multicast address to be left.

**Parameters**

- `addr` – IPv4 multicast address

`static inline struct in\_addr *net_if_router_ipv4(struct net\_if\_router *router)`

Get the IPv4 address of the given router.

**Parameters**

- `router` – a network router

**Returns** pointer to the IPv4 address, or NULL if none

`struct net\_if\_router *net_if_ipv4_router_lookup(struct net\_if *iface, struct in\_addr *addr)`

Check if IPv4 address is one of the routers configured in the system.

**Parameters**

- `iface` – Network interface
- `addr` – IPv4 address

**Returns** Pointer to router information, NULL if cannot be found

```
struct net_if_router *net_if_ipv4_router_find_default(struct net_if *iface, struct in_addr *addr)
```

Find default router for this IPv4 address.

#### Parameters

- *iface* – Network interface. This can be NULL in which case we go through all the network interfaces to find a suitable router.
- *addr* – IPv4 address

**Returns** Pointer to router information, NULL if cannot be found

```
struct net_if_router *net_if_ipv4_router_add(struct net_if *iface, struct in_addr *addr, bool is_default, uint16_t router_lifetime)
```

Add IPv4 router to the system.

#### Parameters

- *iface* – Network interface
- *addr* – IPv4 address
- *is\_default* – Is this router the default one
- *router\_lifetime* – Lifetime of the router

**Returns** Pointer to router information, NULL if could not be added

```
bool net_if_ipv4_router_rm(struct net_if_router *router)
```

Remove IPv4 router from the system.

#### Parameters

- *router* – Router information.

**Returns** True if successfully removed, false otherwise

```
bool net_if_ipv4_addr_mask_cmp(struct net_if *iface, const struct in_addr *addr)
```

Check if the given IPv4 address belongs to local subnet.

#### Parameters

- *iface* – Interface to use. Must be a valid pointer to an interface.
- *addr* – IPv4 address

**Returns** True if address is part of local subnet, false otherwise.

```
bool net_if_ipv4_is_addr_bcast(struct net_if *iface, const struct in_addr *addr)
```

Check if the given IPv4 address is a broadcast address.

#### Parameters

- *iface* – Interface to use. Must be a valid pointer to an interface.
- *addr* – IPv4 address, this should be in network byte order

**Returns** True if address is a broadcast address, false otherwise.

```
static inline struct net_if *net_if_ipv4_select_src_iface(const struct in_addr *dst)
```

Get a network interface that should be used when sending IPv4 network data to destination.

#### Parameters

- *dst* – IPv4 destination address

**Returns** Pointer to network interface to use, NULL if no suitable interface could be found.

```
static inline const struct in_addr *net_if_ipv4_select_src_addr(struct net_if *iface, const  
                                                                struct in_addr *dst)
```

Get a IPv4 source address that should be used when sending network data to destination.

**Parameters**

- *iface* – Interface to use when sending the packet. If the interface is not known, then NULL can be given.
- *dst* – IPv4 destination address

**Returns** Pointer to IPv4 address to use, NULL if no IPv4 address could be found.

```
struct in_addr *net_if_ipv4_get_ll(struct net_if *iface, enum net_addr_state addr_state)
```

Get a IPv4 link local address in a given state.

**Parameters**

- *iface* – Interface to use. Must be a valid pointer to an interface.
- *addr\_state* – IPv4 address state (preferred, tentative, deprecated)

**Returns** Pointer to link local IPv4 address, NULL if no proper IPv4 address could be found.

```
struct in_addr *net_if_ipv4_get_global_addr(struct net_if *iface, enum net_addr_state  
                                           addr_state)
```

Get a IPv4 global address in a given state.

**Parameters**

- *iface* – Interface to use. Must be a valid pointer to an interface.
- *addr\_state* – IPv4 address state (preferred, tentative, deprecated)

**Returns** Pointer to link local IPv4 address, NULL if no proper IPv4 address could be found.

```
void net_if_ipv4_set_netmask(struct net_if *iface, const struct in_addr *netmask)
```

Set IPv4 netmask for an interface.

**Parameters**

- *iface* – Interface to use.
- *netmask* – IPv4 netmask

```
bool net_if_ipv4_set_netmask_by_index(int index, const struct in_addr *netmask)
```

Set IPv4 netmask for an interface index.

**Parameters**

- *index* – Network interface index
- *netmask* – IPv4 netmask

**Returns** True if netmask was added, false otherwise.

```
void net_if_ipv4_set_gw(struct net_if *iface, const struct in_addr *gw)
```

Set IPv4 gateway for an interface.

**Parameters**

- *iface* – Interface to use.
- *gw* – IPv4 address of an gateway

```
bool net_if_ipv4_set_gw_by_index(int index, const struct in\_addr *gw)
```

Set IPv4 gateway for an interface index.

**Parameters**

- `index` – Network interface index
- `gw` – IPv4 address of an gateway

**Returns** True if gateway was added, false otherwise.

```
struct net\_if *net_if_select_src_iface(const struct sockaddr *dst)
```

Get a network interface that should be used when sending IPv6 or IPv4 network data to destination.

**Parameters**

- `dst` – IPv6 or IPv4 destination address

**Returns** Pointer to network interface to use. Note that the function will return the default network interface if the best network interface is not found.

```
void net_if_register_link_cb(struct net\_if\_link\_cb *link, net\_if\_link\_callback\_t cb)
```

Register a link callback.

**Parameters**

- `link` – Caller specified handler for the callback.
- `cb` – Callback to register.

```
void net_if_unregister_link_cb(struct net\_if\_link\_cb *link)
```

Unregister a link callback.

**Parameters**

- `link` – Caller specified handler for the callback.

```
void net_if_call_link_cb(struct net\_if *iface, struct net\_linkaddr *lladdr, int status)
```

Call a link callback function.

**Parameters**

- `iface` – Network interface.
- `lladdr` – Destination link layer address
- `status` – 0 is ok, < 0 error

```
bool net_if_need_calc_rx_checksum(struct net\_if *iface)
```

Check if received network packet checksum calculation can be avoided or not. For example many ethernet devices support network packet offloading in which case the IP stack does not need to calculate the checksum.

**Parameters**

- `iface` – Network interface

**Returns** True if checksum needs to be calculated, false otherwise.

```
bool net_if_need_calc_tx_checksum(struct net\_if *iface)
```

Check if network packet checksum calculation can be avoided or not when sending the packet. For example many ethernet devices support network packet offloading in which case the IP stack does not need to calculate the checksum.

**Parameters**

- `iface` – Network interface

**Returns** True if checksum needs to be calculated, false otherwise.

```
struct net\_if *net_if_get_by_index(int index)
```

Get interface according to index.

This is a syscall only to provide access to the object for purposes of assigning permissions.

**Parameters**

- `index` – Interface index

**Returns** Pointer to interface or NULL if not found.

```
int net_if_get_by_iface(struct net\_if *iface)
```

Get interface index according to pointer.

**Parameters**

- `iface` – Pointer to network interface

**Returns** Interface index

```
void net_if_foreach(net\_if\_cb\_t cb, void *user_data)
```

Go through all the network interfaces and call callback for each interface.

**Parameters**

- `cb` – User-supplied callback function to call
- `user_data` – User specified data

```
int net_if_up(struct net\_if *iface)
```

Bring interface up.

**Parameters**

- `iface` – Pointer to network interface

**Returns** 0 on success

```
static inline bool net_if_is_up(struct net\_if *iface)
```

Check if interface is up.

**Parameters**

- `iface` – Pointer to network interface

**Returns** True if interface is up, False if it is down.

```
int net_if_down(struct net\_if *iface)
```

Bring interface down.

**Parameters**

- `iface` – Pointer to network interface

**Returns** 0 on success

```
int net_if_set_promisc(struct net\_if *iface)
```

Set network interface into promiscuous mode.

Note that not all network technologies will support this.

**Parameters**

- `iface` – Pointer to network interface

**Returns** 0 on success, <0 if error

```
void net_if_unset_promisc(struct net\_if *iface)
```

Set network interface into normal mode.

**Parameters**

- `iface` – Pointer to network interface

`bool net_if_is_promisc(struct net\_if *iface)`

Check if promiscuous mode is set or not.

#### Parameters

- `iface` – Pointer to network interface

**Returns** True if interface is in promisc mode, False if interface is not in in promiscuous mode.

`static inline bool net_if_are_pending_tx_packets(struct net\_if *iface)`

Check if there are any pending TX network data for a given network interface.

#### Parameters

- `iface` – Pointer to network interface

**Returns** True if there are pending TX network packets for this network interface, False otherwise.

`struct net_if_addr`

`#include <net_if.h>` Network Interface unicast IP addresses.

Stores the unicast IP addresses assigned to this network interface.

### Public Members

`struct net_addr address`

IP address

`enum net\_addr\_type addr_type`

How the IP address was set

`enum net\_addr\_state addr_state`

What is the current state of the address

`uint8_t is_infinite`

Is the IP address valid forever

`uint8_t is_used`

Is this IP address used or not

`uint8_t is_mesh_local`

Is this IP address usage limited to the subnet (mesh) or not

`struct net_if_mcast_addr`

`#include <net_if.h>` Network Interface multicast IP addresses.

Stores the multicast IP addresses assigned to this network interface.

### Public Members

struct net\_addr address  
IP address

uint8\_t is\_used  
Is this multicast IP address used or not

uint8\_t is\_joined  
Did we join to this group

struct net\_if\_ipv6\_prefix  
*#include <net\_if.h>* Network Interface IPv6 prefixes.  
Stores the multicast IP addresses assigned to this network interface.

### Public Members

struct *net\_timeout* lifetime  
Prefix lifetime

struct *in6\_addr* prefix  
IPv6 prefix

struct *net\_if* \*iface  
Backpointer to network interface where this prefix is used

uint8\_t len  
Prefix length

uint8\_t is\_infinite  
Is the IP prefix valid forever

uint8\_t is\_used  
Is this prefix used or not

struct net\_if\_router  
*#include <net\_if.h>* Information about routers in the system.  
Stores the router information.

### Public Members

sys\_snode\_t node  
Slist lifetime timer node

struct net\_addr address  
IP address

struct *net\_if* \*iface  
Network interface the router is connected to

uint32\_t life\_start

Router life timer start

uint16\_t lifetime

Router lifetime

uint8\_t is\_used

Is this router used or not

uint8\_t is\_default

Is default router

uint8\_t is\_infinite

Is the router valid forever

struct net\_if\_ipv6

*#include <net\_if.h>*

### Public Members

struct [net\\_if\\_addr](#) unicast[NET\_IF\_MAX\_IPV6\_ADDR]

Unicast IP addresses

struct [net\\_if\\_mcast\\_addr](#) mcast[NET\_IF\_MAX\_IPV6\_MADDR]

Multicast IP addresses

struct [net\\_if\\_ipv6\\_prefix](#) prefix[NET\_IF\_MAX\_IPV6\_PREFIX]

Prefixes

uint32\_t base\_reachable\_time

Default reachable time (RFC 4861, page 52)

uint32\_t reachable\_time

Reachable time (RFC 4861, page 20)

uint32\_t retrans\_timer

Retransmit timer (RFC 4861, page 52)

uint8\_t hop\_limit

IPv6 hop limit

struct net\_if\_ipv4

*#include <net\_if.h>*

### Public Members

```
struct net_if_addr unicast[NET_IF_MAX_IPV4_ADDR]
```

Unicast IP addresses

```
struct net_if_mcast_addr mcast[NET_IF_MAX_IPV4_MADDR]
```

Multicast IP addresses

```
struct in_addr gw
```

Gateway

```
struct in_addr netmask
```

Netmask

```
uint8_t ttl
```

IPv4 time-to-live

```
struct net_if_ip
```

*#include <net\_if.h>* Network interface IP address configuration.

```
struct net_if_config
```

*#include <net\_if.h>* IP and other configuration related data for network interface.

### Public Members

```
struct net_if_ip ip
```

IP address configuration setting

```
struct net_traffic_class
```

*#include <net\_if.h>* Network traffic class.

Traffic classes are used when sending or receiving data that is classified with different priorities. So some traffic can be marked as high priority and it will be sent or received first. Each network packet that is transmitted or received goes through a fifo to a thread that will transmit it.

### Public Members

```
struct k_fifo fifo
```

Fifo for handling this Tx or Rx packet

```
struct k_thread handler
```

Traffic class handler thread

```
k_thread_stack_t *stack
```

Stack for this handler

```
struct net_if_dev
```

*#include <net\_if.h>* Network Interface Device structure.

Used to handle a network interface on top of a device driver instance. There can be many `net_if_dev` instance against the same device.

Such interface is mainly to be used by the link layer, but is also tight to a network context: it then makes the relation with a network context and the network device.

Because of the strong relationship between a device driver and such network interface, each `net_if_dev` should be instantiated by

### Public Members

const struct `device` \*dev

The actually device driver instance the `net_if` is related to

const struct `net_l2` \*const l2

Interface's L2 layer

void \*l2\_data

Interface's private L2 data pointer

struct `net_linkaddr` link\_addr

The hardware link address

uint16\_t mtu

The hardware MTU

struct `net_if`

`#include <net_if.h>` Network Interface structure.

Used to handle a network interface on top of a `net_if_dev` instance. There can be many `net_if` instance against the same `net_if_dev` instance.

### Public Members

struct `net_if_dev` \*if\_dev

The `net_if_dev` instance the `net_if` is related to

struct `net_if_config` config

Network interface instance configuration

struct `net_if_mcast_monitor`

`#include <net_if.h>` Multicast monitor handler struct.

Stores the multicast callback information. Caller must make sure that the variable pointed by this is valid during the lifetime of registration. Typically this means that the variable cannot be allocated from stack.

### Public Members

sys\_snode\_t node

Node information for the slist.

```
struct net_if *iface
```

Network interface

```
net_if_mcast_callback_t cb
```

Multicast callback

```
struct net_if_link_cb
```

*#include <net\_if.h>* Link callback handler struct.

Stores the link callback information. Caller must make sure that the variable pointed by this is valid during the lifetime of registration. Typically this means that the variable cannot be allocated from stack.

### Public Members

```
sys_snode_t node
```

Node information for the slist.

```
net_if_link_callback_t cb
```

Link callback

## L2 Layer Management

- [Overview](#)
- [L2 layer API](#)
- [Network Device drivers](#)
  - [Ethernet device driver](#)
  - [IEEE 802.15.4 device driver](#)
- [API Reference](#)

**Overview** The L2 stack is designed to hide the whole networking link-layer part and the related device drivers from the upper network stack. This is made through a *net\_if* declared in `include/net/net_if.h`.

The upper layers are unaware of implementation details beyond the *net\_if* object and the generic API provided by the L2 layer in `include/net/net_l2.h` as *net\_l2*.

Only the L2 layer can talk to the device driver, linked to the *net\_if* object. The L2 layer dictates the API provided by the device driver, specific for that device, and optimized for working together.

Currently, there are L2 layers for [Ethernet](#), [IEEE 802.15.4 Soft-MAC](#), Bluetooth IPSP, [CANBUS](#), [OpenThread](#), Wi-Fi, and a dummy layer example that can be used as a template for writing a new one.

**L2 layer API** In order to create an L2 layer, or a driver for a specific L2 layer, one needs to understand how the L3 layer interacts with it and how the L2 layer is supposed to behave. See also [network stack architecture](#) for more details. The generic L2 API has these functions:

- `recv()`: All device drivers, once they receive a packet which they put into a *net\_pkt*, will push this buffer to the network stack via `net_recv_data()`. At this point, the network stack does not know what to do with it. Instead, it passes the buffer along to the L2 stack's `recv()` function for

handling. The L2 stack does what it needs to do with the packet, for example, parsing the link layer header, or handling link-layer only packets. The `recv()` function will return `NET_DROP` in case of an erroneous packet, `NET_OK` if the packet was fully consumed by the L2, or `NET_CONTINUE` if the network stack should then handle it.

- `send()`: Similar to receive function, the network stack will call this function to actually send a network packet. All relevant link-layer content will be generated and added by this function. The `send()` function returns the number of bytes sent, or a negative error code if there was a failure sending the network packet.
- `enable()`: This function is used to enable/disable traffic over a network interface. The function returns `<0` if error and `>=0` if no error.
- `get_flags()`: This function will return the capabilities of an L2 driver, for example whether the L2 supports multicast or promiscuous mode.

**Network Device drivers** Network device drivers fully follows Zephyr device driver model as a basis. Please refer to [Device Driver Model](#).

There are, however, two differences:

- The `driver_api` pointer must point to a valid `net_if_api` pointer.
- The network device driver must use `NET_DEVICE_INIT_INSTANCE()` or `ETH_NET_DEVICE_INIT()` for Ethernet devices. These macros will call the `DEVICE_DEFINE()` macro, and also instantiate a unique `net_if` related to the created device driver instance.

Implementing a network device driver depends on the L2 stack it belongs to: [Ethernet](#), [IEEE 802.15.4](#), etc. In the next section, we will describe how a device driver should behave when receiving or sending a network packet. The rest is hardware dependent and is not detailed here.

**Ethernet device driver** On reception, it is up to the device driver to fill-in the network packet with as many data buffers as required. The network packet itself is a `net_pkt` and should be allocated through `net_pkt_rx_alloc_with_buffer()`. Then all data buffers will be automatically allocated and filled by `net_pkt_write()`.

After all the network data has been received, the device driver needs to call `net_recv_data()`. If that call fails, it will be up to the device driver to unreference the buffer via `net_pkt_unref()`.

On sending, the device driver send function will be called, and it is up to the device driver to send the network packet all at once, with all the buffers.

Each Ethernet device driver will need, in the end, to call `ETH_NET_DEVICE_INIT()` like this:

```
ETH_NET_DEVICE_INIT(..., CONFIG_ETH_INIT_PRIORITY,  
                    &the_valid_net_if_api_instance, 1500);
```

**IEEE 802.15.4 device driver** Device drivers for IEEE 802.15.4 L2 work basically the same as for Ethernet. What has been described above, especially for `recv()`, applies here as well. There are two specific differences however:

- It requires a dedicated device driver API: `ieee802154_radio_api`, which overloads `net_if_api`. This is because 802.15.4 L2 needs more from the device driver than just `send()` and `recv()` functions. This dedicated API is declared in `include/net/ieee802154_radio.h`. Each and every IEEE 802.15.4 device driver must provide a valid pointer on such relevantly filled-in API structure.
- Sending a packet is slightly different than in Ethernet. IEEE 802.15.4 sends relatively small frames, 127 bytes all inclusive: frame header, payload and frame checksum. Buffers are meant to fit such frame size limitation. But a buffer containing an IPv6/UDP packet might have more than one fragment. IEEE 802.15.4 drivers handle only one buffer at a time. This is why the `ieee802154_radio_api` requires a tx function pointer which differs from

the `net_if_api` send function pointer. Instead, the IEEE 802.15.4 L2, provides a generic `ieee802154_radio_send()` meant to be given as `net_if` send function. It turn, the implementation of `ieee802154_radio_send()` will ensure the same behavior: sending one buffer at a time through `ieee802154_radio_api` tx function, and unreferencing the network packet only when all the transmission were successful.

Each IEEE 802.15.4 device driver, in the end, will need to call `NET_DEVICE_INIT_INSTANCE()` that way:

```
NET_DEVICE_INIT_INSTANCE(...,
    the_device_init_prio,
    &the_valid_ieee802154_radio_api_instance,
    IEEE802154_L2,
    NET_L2_GET_CTX_TYPE(IEEE802154_L2), 125);
```

## API Reference

### group `net_l2`

Network Layer 2 abstraction layer.

### Enums

#### enum `net_l2_flags`

L2 flags

Values:

enumerator `NET_L2_MULTICAST` = `BIT(0)`

IP multicast supported

enumerator `NET_L2_MULTICAST_SKIP_JOIN_SOLICIT_NODE` = `BIT(1)`

Do not joint solicited node multicast group

enumerator `NET_L2_PROMISC_MODE` = `BIT(2)`

Is promiscuous mode supported

enumerator `NET_L2_POINT_TO_POINT` = `BIT(3)`

Is this L2 point-to-point with tunneling so no need to have IP address etc to network interface.

#### struct `net_l2`

*#include* `<net_l2.h>` Network L2 structure.

Used to provide an interface to lower network stack.

### Public Members

enum `net_verdict` (\*recv)(struct `net_if` \*iface, struct `net_pkt` \*pkt)

This function is used by net core to get iface's L2 layer parsing what's relevant to itself.

```
int (*send)(struct net_if *iface, struct net_pkt *pkt)
```

This function is used by net core to push a packet to lower layer (interface's L2), which in turn might work on the packet relevantly. (adding proper header etc...) Returns a negative error code, or the number of bytes sent otherwise.

```
int (*enable)(struct net_if *iface, bool state)
```

This function is used to enable/disable traffic over a network interface. The function returns <0 if error and >=0 if no error.

```
enum net_l2_flags (*get_flags)(struct net_if *iface)
```

Return L2 flags for the network interface.

## Network Traffic Offloading

- [Network Offloading](#)
  - [Overview](#)
  - [API Reference](#)
- [Socket Offloading](#)
  - [Overview](#)

## Network Offloading

**Overview** The network offloading API provides hooks that a device vendor can use to provide an alternate implementation for an IP stack. This means that the actual network connection creation, data transfer, etc., is done in the vendor HAL instead of the Zephyr network stack.

### API Reference

*group* `net_offload`

Network offloading interface.

### Socket Offloading

**Overview** In addition to the network offloading API, Zephyr allows offloading of networking functionality at the socket API level. With this approach, vendors who provide an alternate implementation of the networking stack, exposing socket API for their networking devices, can easily integrate it with Zephyr.

See `drivers/wifi/simplelink/simplelink_sockets.c` for a sample implementation on how to integrate network offloading at socket level.

## Link Layer Address Handling

- [Overview](#)
- [API Reference](#)

**Overview** The link layer addresses are set for network interfaces so that L2 connectivity works correctly in the network stack. Typically the link layer addresses are 6 bytes long like in Ethernet but for IEEE 802.15.4 the link layer address length is 8 bytes.

## API Reference

*group* `net_linkaddr`

Network link address library.

## Defines

`NET_LINK_ADDR_MAX_LENGTH`

Maximum length of the link address

## Enums

`enum net_link_type`

Type of the link address. This indicates the network technology that this address is used in. Note that in order to save space we store the value into a `uint8_t` variable, so please do not introduce any values  $> 255$  in this enum.

*Values:*

enumerator `NET_LINK_UNKNOWN` = 0

Unknown link address type.

enumerator `NET_LINK_IEEE802154`

IEEE 802.15.4 link address.

enumerator `NET_LINK_BLUETOOTH`

Bluetooth IPSP link address.

enumerator `NET_LINK_ETHERNET`

Ethernet link address.

enumerator `NET_LINK_DUMMY`

Dummy link address. Used in testing apps and loopback support.

enumerator `NET_LINK_CANBUS_RAW`

CANBUS link address.

enumerator `NET_LINK_CANBUS`

6loCAN link address.

## Functions

```
static inline bool net_linkaddr_cmp(struct net\_linkaddr *lladdr1, struct net\_linkaddr *lladdr2)
```

Compare two link layer addresses.

#### Parameters

- lladdr1 – Pointer to a link layer address
- lladdr2 – Pointer to a link layer address

**Returns** True if the addresses are the same, false otherwise.

```
static inline int net_linkaddr_set(struct net\_linkaddr\_storage *lladdr_store, uint8_t *new_addr,  
                                uint8_t new_len)
```

Set the member data of a link layer address storage structure.

#### Parameters

- lladdr\_store – The link address storage structure to change.
- new\_addr – Array of bytes containing the link address.
- new\_len – Length of the link address array. This value should always be <= NET\_LINK\_ADDR\_MAX\_LENGTH.

```
struct net_linkaddr
```

*#include <net\_linkaddr.h>* Hardware link address structure.

Used to hold the link address information

#### Public Members

uint8\_t \*addr

The array of byte representing the address

uint8\_t len

Length of that address array

uint8\_t type

What kind of address is this for

```
struct net_linkaddr_storage
```

*#include <net\_linkaddr.h>* Hardware link address structure.

Used to hold the link address information. This variant is needed when we have to store the link layer address.

Note that you cannot cast this to [net\\_linkaddr](#) as uint8\_t \* is handled differently than uint8\_t addr[] and the fields are purposely in different order.

#### Public Members

uint8\_t type

What kind of address is this for

uint8\_t len

The real length of the ll address.

```
uint8_t addr[6]
```

The array of bytes representing the address

## Ethernet Management

- [Overview](#)
- [API Reference](#)

**Overview** Ethernet management API provides functions to manage the Ethernet network interface low level status. The caller of these functions can:

- raise carrier ON or carrier OFF management events
- raise VLAN enabled or VLAN disabled management events

Typically the carrier OFF event would be generated by the Ethernet device driver when it notices that the Ethernet cable is disconnected. The carrier ON event would be generated if the Ethernet device driver notices that the Ethernet cable is re-connected.

Currently the VLAN events are generated by the Ethernet L2 layer when a specific VLAN tag is either enabled or disabled.

The user application can monitor these events if it needs to act when the corresponding status changes.

## API Reference

*group* ethernet\_mgmt

Ethernet library.

### Functions

```
void ethernet_mgmt_raise_carrier_on_event(struct net_if *iface)
```

Raise CARRIER\_ON event when Ethernet is connected.

#### Parameters

- *iface* – Ethernet network interface.

```
void ethernet_mgmt_raise_carrier_off_event(struct net_if *iface)
```

Raise CARRIER\_OFF event when Ethernet is disconnected.

#### Parameters

- *iface* – Ethernet network interface.

```
void ethernet_mgmt_raise_vlan_enabled_event(struct net_if *iface, uint16_t tag)
```

Raise VLAN\_ENABLED event when VLAN is enabled.

#### Parameters

- *iface* – Ethernet network interface.
- *tag* – VLAN tag which is enabled.

```
void ethernet_mgmt_raise_vlan_disabled_event(struct net\_if *iface, uint16_t tag)
```

Raise VLAN\_DISABLED event when VLAN is disabled.

#### Parameters

- `iface` – Ethernet network interface.
- `tag` – VLAN tag which is disabled.

## Traffic Classification

**Overview** [Traffic classification](#) is an automated process that categorizes computer network traffic according to various parameters. For Zephyr, the VLAN priority code point (PCP) is used to classify both received and sent network packets. See more information about VLAN priority at [IEEE 802.1Q](#).

By default, all network traffic is treated equal in Zephyr. If desired, the option **`:kconfig: CONFIG_NET_TC_TX_COUNT`** can be used to set the number of transmit queues. The option **`:kconfig: CONFIG_NET_TC_RX_COUNT`** can be used to set the number of receive queues. Each traffic class queue corresponds to a specific kernel work queue. Each kernel work queue has a priority. The VLAN priority is mapped to a certain traffic class according to rules specified in [IEEE 802.1Q spec](#) chapter I.3, chapter 8.6.6 table 8-4, and chapter 34.5 table 34-1. Each traffic class is in turn mapped to a certain kernel work queue. The maximum number of traffic classes for both Rx and Tx is 8.

See [subsys/net/ip/net\\_tc.c](#) for details of how various mappings are done.

## Network Shell

Network shell provides helpers for figuring out network status, enabling/disabling features, and issuing commands like ping or DNS resolving. Note that `net-shell` should probably not be used in production code as it will require extra memory. See also [generic shell](#) for detailed shell information.

The following net-shell commands are implemented:

Table 6: net-shell commands

Com-mand	Description
net al-locs	Print network memory allocations. Only available if <code>:kconfig: `CONFIG_NET_DEBUG_NET_PKT_ALLOC`</code> is set.
net arp	Print information about IPv4 ARP cache. Only available if <code>:kconfig: `CONFIG_NET_ARP`</code> is set in IPv4 enabled networks.
net cap-ture	Monitor network traffic See <a href="#">Monitor Network Traffic</a> for details.
net conn	Print information about network connections.
net dns	Show how DNS is configured. The command can also be used to resolve a DNS name. Only available if <code>:kconfig: `CONFIG_DNS_RESOLVER`</code> is set.
net events	Enable network event monitoring. Only available if <code>:kconfig: `CONFIG_NET_MGMT_EVENT_MONITOR`</code> is set.
net gtp	Print information about gPTP support. Only available if <code>:kconfig: `CONFIG_NET_GPTP`</code> is set.
net iface	Print information about network interfaces.
net ipv6	Print IPv6 specific information and configuration. Only available if <code>:kconfig: `CONFIG_NET_IPV6`</code> is set.
net mem	Print information about network memory usage. The command will print more information if <code>:kconfig: `CONFIG_NET_BUF_POOL_USAGE`</code> is set.
net nbr	Print neighbor information. Only available if <code>:kconfig: `CONFIG_NET_IPV6`</code> is set.
net ping	Ping a network host.
net route	Show IPv6 network routes. Only available if <code>:kconfig: `CONFIG_NET_ROUTE`</code> is set.
net stats	Show network statistics.
net tcp	Connect/send data/close TCP connection. Only available if <code>:kconfig: `CONFIG_NET_TCP`</code> is set.
net vlan	Show Ethernet virtual LAN information. Only available if <code>:kconfig: `CONFIG_NET_VLAN`</code> is set.

## 7.20.6 Time Sensitive Networking

### generic Precision Time Protocol (gPTP)

- [Overview](#)
- [Supported features](#)
- [Supported hardware](#)
- [Enabling the stack](#)
- [Application interfaces](#)
- [Testing](#)
- [API Reference](#)

**Overview** This gPTP stack supports the protocol and procedures as defined in the [IEEE 802.1AS-2011 standard](#) (Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks).

**Supported features** The stack handles communications and state machines defined in the [IEEE 802.1AS-2011 standard](#). Mandatory requirements for a full-duplex point-to-point link endpoint, as defined in Annex A of the standard, are supported.

The stack is in principle capable of handling communications on multiple network interfaces (also defined as “ports” in the standard) and thus act as a 802.1AS bridge. However, this mode of operation has not been validated on the Zephyr OS.

**Supported hardware** Although the stack itself is hardware independent, Ethernet frame timestamping support must be enabled in ethernet drivers.

Boards supported:

- frdm\_k64f
- sam\_e70\_xplained
- native\_posix (only usable for simple testing, limited capabilities due to lack of hardware clock)
- qemu\_x86 (emulated, limited capabilities due to lack of hardware clock)

**Enabling the stack** The following configuration option must be enabled in `prj.conf` file.

- `:kconfig: `CONFIG_NET_GPTP``

**Application interfaces** Only two Application Interfaces as defined in section 9 of the standard are available:

- ClockTargetPhaseDiscontinuity interface (`gptp_register_phase_dis_cb()`)
- ClockTargetEventCapture interface (`gptp_event_capture()`)

**Testing** The stack has been informally tested using the [OpenAVnu gPTP](#) and [Linux ptp4l](#) daemons. The gPTP sample application from the Zephyr source distribution can be used for testing.

## API Reference

group gptp

generic Precision Time Protocol (gPTP) support

### Typedefs

```
typedef void (*gptp_phase_dis_callback_t)(uint8_t *gm_identity, uint16_t *time_base, struct gptp_scaled_ns *last_gm_ph_change, double *last_gm_freq_change)
```

Define callback that is called after a phase discontinuity has been sent by the grandmaster.

**Param gm\_identity** A pointer to first element of a ClockIdentity array. The size of the array is GPTP\_CLOCK\_ID\_LEN.

**Param time\_base** A pointer to the value of timeBaseIndicator of the current grandmaster.

**Param last\_gm\_ph\_change** A pointer to the value of lastGmPhaseChange received from grandmaster.

**Param last\_gm\_freq\_change** A pointer to the value of lastGmFreqChange received from the grandmaster.

typedef void (\*gptp\_port\_cb\_t)(int port, struct [net\\_if](#) \*iface, void \*user\_data)

Callback used while iterating over gPTP ports.

**Param port** Port number

**Param iface** Pointer to network interface

**Param user\_data** A valid pointer to user data or NULL

## Functions

void gptp\_register\_phase\_dis\_cb(struct [gptp\\_phase\\_dis\\_cb](#) \*phase\_dis,  
[gptp\\_phase\\_dis\\_callback\\_t](#) cb)

Register a phase discontinuity callback.

### Parameters

- phase\_dis – Caller specified handler for the callback.
- cb – Callback to register.

void gptp\_unregister\_phase\_dis\_cb(struct [gptp\\_phase\\_dis\\_cb](#) \*phase\_dis)

Unregister a phase discontinuity callback.

### Parameters

- phase\_dis – Caller specified handler for the callback.

void gptp\_call\_phase\_dis\_cb(void)

Call a phase discontinuity callback function.

int gptp\_event\_capture(struct [net\\_ptp\\_time](#) \*slave\_time, bool \*gm\_present)

Get gPTP time.

### Parameters

- slave\_time – A pointer to structure where timestamp will be saved.
- gm\_present – A pointer to a boolean where status of the presence of a grand master will be saved.

**Returns** Error code. 0 if no error.

char \*gptp\_sprint\_clock\_id(const uint8\_t \*clk\_id, char \*output, size\_t output\_len)

Utility function to print clock id to a user supplied buffer.

### Parameters

- clk\_id – Clock id
- output – Output buffer
- output\_len – Output buffer len

**Returns** Pointer to output buffer

void gptp\_foreach\_port([gptp\\_port\\_cb\\_t](#) cb, void \*user\_data)

Go through all the gPTP ports and call callback for each of them.

### Parameters

- cb – User-supplied callback function to call
- user\_data – User specified data

```
struct gptp_domain *gptp_get_domain(void)
```

Get gPTP domain.

This contains all the configuration / status of the gPTP domain.

**Returns** Pointer to domain or NULL if not found.

```
void gptp_clk_src_time_invoke(struct gptp_clk_src_time_invoke_params *arg)
```

This interface is used by the ClockSource entity to provide time to the ClockMaster entity of a time-aware system.

**Parameters**

- arg – Current state and parameters of the ClockSource entity.

```
struct gptp_hdr *gptp_get_hdr(struct net_pkt *pkt)
```

Return pointer to gPTP packet header in network packet.

**Parameters**

- pkt – Network packet (received or sent)

**Returns** Pointer to gPTP header.

```
struct gptp_scaled_ns
```

*#include <gptp.h>* Scaled Nanoseconds.

**Public Members**

```
int32_t high
```

High half.

```
int64_t low
```

Low half.

```
struct gptp_uscaled_ns
```

*#include <gptp.h>* UScaled Nanoseconds.

**Public Members**

```
uint32_t high
```

High half.

```
uint64_t low
```

Low half.

```
struct gptp_port_identity
```

*#include <gptp.h>* Port Identity.

**Public Members**

```
uint8_t clk_id[GPTP_CLOCK_ID_LEN]
```

Clock identity of the port.

uint16\_t port\_number  
Number of the port.

struct gptp\_flags  
*#include <gptp.h>*

### Public Members

uint8\_t octets[2]  
Byte access.

uint16\_t all  
Whole field access.

struct gptp\_hdr  
*#include <gptp.h>*

### Public Members

uint8\_t message\_type  
Type of the message.

uint8\_t transport\_specific  
Transport specific, always 1.

uint8\_t ptp\_version  
Version of the PTP, always 2.

uint8\_t reserved0  
Reserved field.

uint16\_t message\_length  
Total length of the message from the header to the last TLV.

uint8\_t domain\_number  
Domain number, always 0.

uint8\_t reserved1  
Reserved field.

struct *gptp\_flags* flags  
Message flags.

int64\_t correction\_field  
Correction Field. The content depends of the message type.

uint32\_t reserved2

Reserved field.

struct [gptp\\_port\\_identity](#) port\_id

Port Identity of the sender.

uint16\_t sequence\_id

Sequence Id.

uint8\_t control

Control value. Sync: 0, Follow-up: 2, Others: 5.

int8\_t log\_msg\_interval

Message Interval in Log2 for Sync and Announce messages.

struct gptp\_phase\_dis\_cb

*#include <gptp.h>* Phase discontinuity callback structure.

Stores the phase discontinuity callback information. Caller must make sure that the variable pointed by this is valid during the lifetime of registration. Typically this means that the variable cannot be allocated from stack.

## Public Members

sys\_snode\_t node

Node information for the slist.

[gptp\\_phase\\_dis\\_callback\\_t](#) cb

Phase discontinuity callback.

struct gptp\_clk\_src\_time\_invoke\_params

*#include <gptp.h>* ClockSourceTime.invoke function parameters.

Parameters passed by ClockSourceTime.invoke function.

## Public Members

double last\_gm\_freq\_change

Frequency change on the last Time Base Indicator Change.

struct [net\\_ptp\\_extended\\_time](#) src\_time

The time this function is invoked.

struct [gptp\\_scaled\\_ns](#) last\_gm\_phase\_change

Phase change on the last Time Base Indicator Change.

uint16\_t time\_base\_indicator

Time Base - changed only if Phase or Frequency changes.

## Precision Time Protocol (PTP) time format

- [Overview](#)
- [API Reference](#)

**Overview** The PTP time struct can store time information in high precision format (nanoseconds). The extended timestamp format can store the time in fractional nanoseconds accuracy. The PTP time format is used in [generic Precision Time Protocol \(gPTP\)](#) implementation.

### API Reference

*group* `ptp_time`

Precision Time Protocol time specification.

`struct net_ptp_time`

*#include* `<ptp_time.h>` Precision Time Protocol Timestamp format.

This structure represents a timestamp according to the Precision Time Protocol standard.

Seconds are encoded as a 48 bits unsigned integer. Nanoseconds are encoded as a 32 bits unsigned integer.

#### Public Members

`union net_ptp_time`.[\[anonymous\]](#) [\[anonymous\]](#)

Seconds encoded on 48 bits.

`uint32_t` `nanosecond`

Nanoseconds.

`struct net_ptp_extended_time`

*#include* `<ptp_time.h>` Precision Time Protocol Extended Timestamp format.

This structure represents an extended timestamp according to the Precision Time Protocol standard.

Seconds are encoded as 48 bits unsigned integer. Fractional nanoseconds are encoded as 48 bits, their unit is  $2^{(-16)}$  ns.

#### Public Members

`union net_ptp_extended_time`.[\[anonymous\]](#) [\[anonymous\]](#)

Seconds encoded on 48 bits.

`union net_ptp_extended_time`.[\[anonymous\]](#) [\[anonymous\]](#)

Fractional nanoseconds on 48 bits.

## 7.20.7 Controller Area Network

### Controller Area Network (CAN)

- [Overview](#)
- [Sending](#)
- [Receiving](#)
- [Setting the bitrate](#)
- [SocketCAN](#)
- [Samples](#)
- [API Reference](#)

**Overview** Controller Area Network is a two-wire serial bus specified by the Bosch CAN Specification, Bosch CAN with Flexible Data-Rate specification and the ISO 11898-1:2003 standard. CAN is mostly known for its application in the automotive domain. However, it is also used in home and industrial automation and other products.

A CAN transceiver is an external device that converts the logic level signals from the CAN controller to the bus-levels. The bus lines are called CAN High (CAN H) and CAN Low (CAN L). The transmit wire from the controller to the transceiver is called CAN TX, and the receive wire is called CAN RX. These wires use the logic levels whereas the bus-level is interpreted differentially between CAN H and CAN L. The bus can be either in the recessive (logical one) or dominant (logical zero) state. The recessive state is when both lines, CAN H and CAN L, are at roughly at the same voltage level. This state is also the idle state. To write a dominant bit to the bus, open-drain transistors tie CAN H to Vdd and CAN L to ground. The first and last node use a 120-ohm resistor between CAN H and CAN L to terminate the bus. The dominant state always overrides the recessive state. This structure is called a wired-AND.

**Warning:** CAN controllers can only initialize when the bus is in the idle (recessive) state for at least 11 recessive bits. Therefore you have to make sure that CAN RX is high, at least for a short time. This is also necessary for loopback mode.

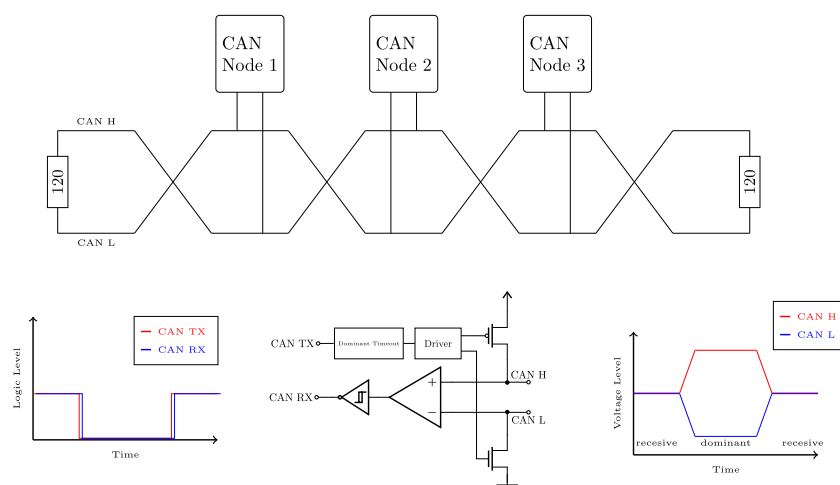

Figure 1: CAN Transceiver, from Logic Levels to Bus Levels. ©Alexander Wachter

The bit-timing as defined in ISO 11898-1:2003 looks as following:

Figure 2: CAN Timing. ©Alexander Wachter

A single bit is split into four segments.

- **Sync\_Seg:** The nodes synchronize at the edge of the Sync\_Seg. It is always one time quantum in length.
- **Prop\_Seg:** The signal propagation delay of the bus and other delays of the transceiver and node.
- **Phase\_Seg1 and Phase\_Seg2 :** Define the sampling point. The bit is sampled at the end of Phase\_Seg1.

The bit-rate is calculated from the time of a time quantum and the values defined above. A bit has the length of Sync\_Seg plus Prop\_Seg plus Phase\_Seg1 plus Phase\_Seg2 multiplied by the time of single time quantum. The bit-rate is the inverse of the length of a single bit.

A bit is sampled at the sampling point. The sample point is between Phase\_Seg1 and Phase\_Seg2 and therefore is a parameter that the user needs to choose. The CiA recommends setting the sample point to 87.5% of the bit.

The resynchronization jump width (SJW) defines the amount of time quantum the sample point can be moved. The sample point is moved when resynchronization is needed.

The timing parameters (SJW, bitrate and sampling point, or bitrate, Prop\_Seg, Phase\_Seg1 and Phase\_Seg2) are initially set from the device-tree and can be changed at run-time from the timing-API.

CAN uses so-called identifiers to identify the frame instead of addresses to identify a node. This identifier can either have 11-bit width (Standard or Basic Frame) or 29-bit in case of an Extended Frame. The Zephyr CAN API supports both Standard and Extended identifiers concurrently. A CAN frame starts with a dominant Start Of Frame bit. After that, the identifiers follow. This phase is called the arbitration phase. During the arbitration phase, write collisions are allowed. They resolve by the fact that dominant bits override recessive bits. Nodes monitor the bus and notice when their transmission is being overridden and in case, abort their transmission. This effectively gives lower number identifiers priority over higher number identifiers.

Filters are used to whitelist identifiers that are of interest for the specific node. An identifier that doesn't match any filter is ignored. Filters can either match exactly or a specified part of the identifier. This method is called masking. As an example, a mask with 11 bits set for standard or 29 bits set for extended identifiers must match perfectly. Bits that are set to zero in the mask are ignored when matching an identifier. Most CAN controllers implement a limited number of filters in hardware. The number of filters is also limited in Kconfig to save memory.

Errors may occur during transmission. In case a node detects an erroneous frame, it partially overrides the current frame with an error-frame. Error-frames can either be error passive or error active, depending on the state of the controller. In case the controller is in error active state, it sends six consecutive dominant bits, which is a violation of the stuffing rule that all nodes can detect. The sender may resend the frame right after.

An initialized node can be in one of the following states:

- Error-active
- Error-passive
- Bus-off

After initialization, the node is in the error-active state. In this state, the node is allowed to send active error frames, ACK, and overload frames. Every node has a receive- and transmit-error counter. If either the receive- or the transmit-error counter exceeds 127, the node changes to error-passive state. In this state, the node is not allowed to send error-active frames anymore. If the transmit-error counter increases further to 255, the node changes to the bus-off state. In this state, the node is not allowed to send any dominant bits to the bus. Nodes in the bus-off state may recover after receiving 128 occurrences of 11 concurrent recessive bits.

You can read more about CAN bus in this [CAN Wikipedia article](#).

Zephyr supports following CAN features:

- Standard and Extended Identifiers
- Filters with Masking
- Loopback and Silent mode
- Remote Request

**Sending** The following code snippets show how to send data.

This basic sample sends a CAN frame with standard identifier 0x123 and eight bytes of data. When passing NULL as the callback, as shown in this example, the send function blocks until the frame is sent and acknowledged by at least one other node or an error occurred. The timeout only takes effect on acquiring a mailbox. When a transmitting mailbox is assigned, sending cannot be canceled.

```
struct zcan_frame frame = {
    .id_type = CAN_STANDARD_IDENTIFIER,
    .rtr = CAN_DATAFRAME,
    .id = 0x123,
    .dlc = 8,
    .data = {1,2,3,4,5,6,7,8}
};
const struct device *can_dev;
int ret;

can_dev = device_get_binding("CAN_0");

ret = can_send(can_dev, &frame, K_MSEC(100), NULL, NULL);
if (ret != CAN_TX_OK) {
    LOG_ERR("Sending failed [%d]", ret);
}
```

This example shows how to send a frame with extended identifier 0x1234567 and two bytes of data. The provided callback is called when the message is sent, or an error occurred. Passing `K_FOREVER` to the timeout causes the function to block until a transfer mailbox is assigned to the frame or an error occurred. It does not block until the message is sent like the example above.

```
void tx_irq_callback(uint32_t error_flags, void *arg)
{
    char *sender = (char *)arg;

    if (error_flags) {
        LOG_ERR("Sendig failed [%d]\nSender: %s\n", error_flags, sender);
    }
}

int send_function(const struct device *can_dev)
{
    struct zcan_frame frame = {
        .id_type = CAN_EXTENDED_IDENTIFIER,
        .rtr = CAN_DATAFRAME,
        .id = 0x1234567,
        .dlc = 2
    };

    frame.data[0] = 1;
```

(continues on next page)

(continued from previous page)

```

    frame.data[1] = 2;

    return can_send(can_dev, &frame, K_FOREVER, tx_irq_callback, "Sender 1");
}

```

**Receiving** Frames are only received when they match a filter. The following code snippets show how to receive frames by attaching filters.

Here we have an example for a receiving callback. It is used for `can_attach_isr` or `can_attach_workq`. The argument `arg` is passed when the filter is attached.

```

void rx_callback_function(struct zcan_frame *frame, void *arg)
{
    ... do something with the frame ...
}

```

The following snippet shows how to attach a filter with an interrupt callback. It is the most efficient but also the most critical way to receive messages. The callback function is called from an interrupt context, which means that the callback function should be as short as possible and must not block. Attaching ISRs is not allowed from userspace context.

The filter for this example is configured to match the identifier 0x123 exactly.

```

const struct zcan_filter my_filter = {
    .id_type = CAN_STANDARD_IDENTIFIER,
    .rtr = CAN_DATAFRAME,
    .id = 0x123,
    .rtr_mask = 1,
    .id_mask = CAN_STD_ID_MASK
};

int filter_id;
const struct device *can_dev;

can_dev = device_get_binding("CAN_0");

filter_id = can_attach_isr(can_dev, rx_callback_function, callback_arg, &my_filter);
if (filter_id < 0) {
    LOG_ERR("Unable to attach isr [%d]", filter_id);
}

```

This example shows how to attach a callback from a work-queue. In contrast to the `can_attach_isr` function, here the callback is called from the work-queue provided. In this case, it is the system work queue. Blocking is generally allowed in the callback but could result in a frame backlog when it is not limited. For the reason of a backlog, a ring-buffer is applied for every attached filter. The size of this buffer can be adjusted in Kconfig. This function is not yet callable from userspace context but will be in the future.

The filter for this example is configured to match a filter range from 0x120 to x12f.

```

const struct zcan_filter my_filter = {
    .id_type = CAN_STANDARD_IDENTIFIER,
    .rtr = CAN_DATAFRAME,
    .id = 0x120,
    .rtr_mask = 1,
    .id_mask = 0x7F0
};

struct zcan_work rx_work;

```

(continues on next page)

(continued from previous page)

```

int filter_id;
const struct device *can_dev;

can_dev = device_get_binding("CAN_0");

filter_id = can_attach_workq(can_dev, &k_sys_work_q, &rx_work, callback_arg, callback_
↪arg, &my_filter);
if (filter_id < 0) {
    LOG_ERR("Unable to attach isr [%d]", filter_id);
}

```

Here an example for `can_attach_msgq` is shown. With this function, it is possible to receive frames synchronously. This function can be called from userspace context. The size of the message queue should be as big as the expected backlog.

The filter for this example is configured to match the extended identifier 0x1234567 exactly.

```

const struct zcan_filter my_filter = {
    .id_type = CAN_EXTENDED_IDENTIFIER,
    .rtr = CAN_DATAFRAME,
    .id = 0x1234567,
    .rtr_mask = 1,
    .id_mask = CAN_EXT_ID_MASK
};
CAN_DEFINE_MSGQ(my_can_msgq, 2);
struct zcan_frame rx_frame;
int filter_id;
const struct device *can_dev;

can_dev = device_get_binding("CAN_0");

filter_id = can_attach_msgq(can_dev, &my_can_msgq, &my_filter);
if (filter_id < 0) {
    LOG_ERR("Unable to attach isr [%d]", filter_id);
    return;
}

while (true) {
    k_msgq_get(&my_can_msgq, &rx_frame, K_FOREVER);
    ... do something with the frame ...
}

```

`can_detach` removes the given filter.

```
can_detach(can_dev, filter_id);
```

**Setting the bitrate** The bitrate and sampling point is initially set at runtime. To change it from the application, one can use the `can_set_timing` API. This function takes three arguments. The first timing parameter sets the timing for classic CAN and arbitration phase for CAN-FD. The second parameter sets the timing of the data phase for CAN-FD. For classic CAN, you can use only the first parameter and put NULL to the second one. The `can_calc_timing` function can calculate timing from a bitrate and sampling point in permille. The following example sets the bitrate to 250k baud with the sampling point at 87.5%.

```

struct can_timing timing;
const struct device *can_dev;

```

(continues on next page)

(continued from previous page)

```

int ret;

can_dev = device_get_binding("CAN_0");

ret = can_calc_timing(can_dev, &timing, 250000, 875);
if (ret > 0) {
    LOG_INF("Sample-Point error: %d", ret);
}

if (ret < 0) {
    LOG_ERR("Failed to calc a valid timing");
    return;
}

ret = can_set_timing(can_dev, &timing, NULL);
if (ret != 0) {
    LOG_ERR("Failed to set timing");
}

```

**SocketCAN** Zephyr additionally supports SocketCAN, a BSD socket implementation of the Zephyr CAN API. SocketCAN brings the convenience of the well-known BSD Socket API to Controller Area Networks. It is compatible with the Linux SocketCAN implementation, where many other high-level CAN projects build on top. Note that frames are routed to the network stack instead of passed directly, which adds some computation and memory overhead.

**Samples** We have two ready-to-build samples demonstrating use of the Zephyr CAN API Zephyr CAN sample and SocketCAN sample.

## API Reference

*group* can\_interface  
CAN Interface.

### Defines

CAN\_EX\_ID

CAN\_MAX\_STD\_ID

CAN\_STD\_ID\_MASK

CAN\_EXT\_ID\_MASK

CAN\_MAX\_DLC

CANFD\_MAX\_DLC

CAN\_MAX\_DLEN

CAN\_TX\_OK

send successfully

CAN\_TX\_ERR

general send error

CAN\_TX\_ARB\_LOST

bus arbitration lost during sending

CAN\_TX\_BUS\_OFF

controller is in bus off state

CAN\_TX\_UNKNOWN

unexpected error

CAN\_TX\_EINVAL

invalid parameter

CAN\_NO\_FREE\_FILTER

attach\_\* failed because there is no unused filter left

CAN\_TIMEOUT

operation timed out

CAN\_DEFINE\_MSGQ(name, size)

Statically define and initialize a can message queue.

The message queue's ring buffer contains space for *size* messages.

**Parameters**

- **name** – Name of the message queue.
- **size** – Number of can messages.

CAN\_SJW\_NO\_CHANGE

SJW value to indicate that the SJW should not be changed

CONFIG\_CAN\_WORKQ\_FRAMES\_BUF\_CNT

## Typedefs

```
typedef uint32_t canid_t
```

```
typedef void (*can_tx_callback_t)(uint32_t error_flags, void *arg)
```

Define the application callback handler function signature.

**Param error\_flags** status of the performed send operation

**Param arg** argument that was passed when the message was sent

```
typedef void (*can_rx_callback_t)(struct zcan_frame *msg, void *arg)
```

Define the application callback handler function signature for receiving.

**Param msg** received message

**Param arg** argument that was passed when the filter was attached

```
typedef void (*can_state_change_isr_t)(enum can_state state, struct can_bus_err_cnt err_cnt)
```

Defines the state change isr handler function signature.

**Param state** state of the node

**Param err\_cnt** struct with the error counter values

```
typedef int (*can_set_timing_t)(const struct device *dev, const struct can_timing *timing, const struct can_timing *timing_data)
```

```
typedef int (*can_set_mode_t)(const struct device *dev, enum can_mode mode)
```

```
typedef int (*can_send_t)(const struct device *dev, const struct zcan_frame *msg, k_timeout_t timeout, can_tx_callback_t callback_isr, void *callback_arg)
```

```
typedef int (*can_attach_msgq_t)(const struct device *dev, struct k_msgq *msg_q, const struct zcan_filter *filter)
```

```
typedef int (*can_attach_isr_t)(const struct device *dev, can_rx_callback_t isr, void *callback_arg, const struct zcan_filter *filter)
```

```
typedef void (*can_detach_t)(const struct device *dev, int filter_id)
```

```
typedef int (*can_recover_t)(const struct device *dev, k_timeout_t timeout)
```

```
typedef enum can_state (*can_get_state_t)(const struct device *dev, struct can_bus_err_cnt *err_cnt)
```

```
typedef void (*can_register_state_change_isr_t)(const struct device *dev, can_state_change_isr_t isr)
```

```
typedef int (*can_get_core_clock_t)(const struct device *dev, uint32_t *rate)
```

## Enums

```
enum can_id
```

*can\_id* enum Define if the message has a standard (11bit) or extended (29bit) identifier

*Values:*

enumerator CAN\_STANDARD\_IDENTIFIER

enumerator CAN\_EXTENDED\_IDENTIFIER

enum can\_rtr

can\_rtr enum Define if the message is a data or remote frame

*Values:*

enumerator CAN\_DATAFRAME

enumerator CAN\_REMOTEREQUEST

enum can\_mode

can\_mode enum Defines the mode of the can controller

*Values:*

enumerator CAN\_NORMAL\_MODE

enumerator CAN\_SILENT\_MODE

enumerator CAN\_LOOPBACK\_MODE

enumerator CAN\_SILENT\_LOOPBACK\_MODE

enum can\_state

can\_state enum Defines the possible states of the CAN bus

*Values:*

enumerator CAN\_ERROR\_ACTIVE

enumerator CAN\_ERROR\_PASSIVE

enumerator CAN\_BUS\_OFF

enumerator CAN\_BUS\_UNKNOWN

## Functions

static inline uint8\_t can\_dlc\_to\_bytes(uint8\_t dlc)

Convert the DLC to the number of bytes.

This function converts a the Data Length Code to the number of bytes.

### Parameters

- dlc – The Data Length Code

**Return values** Number – of bytes

static inline uint8\_t can\_bytes\_to\_dlc(uint8\_t num\_bytes)

Convert a number of bytes to the DLC.

This function converts a number of bytes to the Data Length Code

### Parameters

- `num_bytes` – The number of bytes

**Return values** The – DLC

```
int can_send(const struct device *dev, const struct zcan_frame *msg, k_timeout_t timeout,  
             can_tx_callback_t callback_isr, void *callback_arg)
```

Perform data transfer to CAN bus.

This routine provides a generic interface to perform data transfer to the can bus. Use *can\_write()* for simple write.

•

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `msg` – Message to transfer.
- `timeout` – Waiting for empty tx mailbox timeout or `K_FOREVER`.
- `callback_isr` – Is called when message was sent or a transmission error occurred. If NULL, this function is blocking until message is sent. This must be NULL if called from user mode.
- `callback_arg` – This will be passed whenever the isr is called.

#### Return values

- 0 – If successful.
- `CAN_TX_*` – on failure.

```
static inline int can_write(const struct device *dev, const uint8_t *data, uint8_t length, uint32_t  
                           id, enum can_rtr rtr, k_timeout_t timeout)
```

Write a set amount of data to the can bus.

This routine writes a set amount of data synchronously.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `data` – Data to send.
- `length` – Number of bytes to write (max. 8).
- `id` – Identifier of the can message.
- `rtr` – Send remote transmission request or data frame
- `timeout` – Waiting for empty tx mailbox timeout or `K_FOREVER`

#### Return values

- 0 – If successful.
- `-EIO` – General input / output error.
- `-EINVAL` – if `length > 8`.

```
int can_attach_workq(const struct device *dev, struct k_work_q *work_q, struct zcan_work  
                    *work, can_rx_callback_t callback, void *callback_arg, const struct  
                    zcan_filter *filter)
```

Attach a CAN work queue to a single or group of identifiers.

This routine attaches a work queue to identifiers specified by a filter. Whenever the filter matches, the message is pushed to the buffer of the *zcan\_work* structure and the work element is put to the workqueue. If a message passes more than one filter the priority of the match is

hardware dependent. A CAN work queue can be attached to more than one filter. The work queue must be initialized before and the caller must have appropriate permissions on it.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `work_q` – Pointer to the already initialized work queue.
- `work` – Pointer to a [zcan\\_work](#). The work will be initialized.
- `callback` – This function is called by workq whenever a message arrives.
- `callback_arg` – Is passed to the callback when called.
- `filter` – Pointer to a [zcan\\_filter](#) structure defining the id filtering.

#### Return values

- `filter_id` – on success.
- `CAN_NO_FREE_FILTER` – if there is no filter left.

```
int can_attach_msgq(const struct device *dev, struct k\_msgq *msg_q, const struct zcan\_filter
                    *filter)
```

Attach a message queue to a single or group of identifiers.

This routine attaches a message queue to identifiers specified by a filter. Whenever the filter matches, the message is pushed to the queue. If a message passes more than one filter the priority of the match is hardware dependent. A message queue can be attached to more than one filter. The message queue must be initialized before, and the caller must have appropriate permissions on it.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `msg_q` – Pointer to the already initialized message queue.
- `filter` – Pointer to a [zcan\\_filter](#) structure defining the id filtering.

#### Return values

- `filter_id` – on success.
- `CAN_NO_FREE_FILTER` – if there is no filter left.

```
static inline int can_attach_isr(const struct device *dev, can\_rx\_callback\_t isr, void
                                *callback_arg, const struct zcan\_filter *filter)
```

Attach an isr callback function to a single or group of identifiers.

This routine attaches an isr callback to identifiers specified by a filter. Whenever the filter matches, the callback function is called with isr context. If a message passes more than one filter the priority of the match is hardware dependent. A callback function can be attached to more than one filter.

•

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `isr` – Callback function pointer.
- `callback_arg` – This will be passed whenever the isr is called.
- `filter` – Pointer to a [zcan\\_filter](#) structure defining the id filtering.

#### Return values

- `filter_id` – on success.

- `CAN_NO_FREE_FILTER` – if there is no filter left.

`void can_detach(const struct device *dev, int filter_id)`

Detach an isr or message queue from the identifier filtering.

This routine detaches an isr callback or message queue from the identifier filtering.

•

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `filter_id` – filter id returned by `can_attach_isr` or `can_attach_msgq`.

**Return values** `none` –

`int can_get_core_clock(const struct device *dev, uint32_t *rate)`

Read the core clock value.

Returns the core clock value. One time quantum is 1/core clock.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `rate` – **[out]** controller clock rate

#### Return values

- `0` – on success
- `negative` – on error

`int can_calc_timing(const struct device *dev, struct can_timing *res, uint32_t bitrate, uint16_t sample_pnt)`

Calculate timing parameters from bitrate and sample point.

Calculate the timing parameters from a given bitrate in bits/s and the sampling point in permill (1/1000) of the entire bit time. The bitrate must always match perfectly. If no result can be given for the, give parameters, `-EINVAL` is returned. The `sample_pnt` does not always match perfectly. The algorithm tries to find the best match possible.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `res` – Result is written into the *can\_timing* struct provided.
- `bitrate` – Target bitrate in bits/s
- `sample_pnt` – Sampling point in permill of the entire bit time.

#### Return values

- `Positive` – sample point error on success
- `-EINVAL` – if there is no solution for the desired values
- `-EIO` – if `core_clock` is not available

`int can_calc_prescaler(const struct device *dev, struct can_timing *timing, uint32_t bitrate)`

Fill in the prescaler value for a given bitrate and timing.

Fill the prescaler value in the timing struct. `sjw`, `prop_seg`, `phase_seg1` and `phase_seg2` must be given. The returned bitrate error is remainder of the division of the clockrate by the bitrate times the timing segments.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.

- `timing` – Result is written into the `can_timing` struct provided.
- `bitrate` – Target bitrate.

**Return values**

- `bitrate` – error
- `negative` – on error

```
int can_set_mode(const struct device *dev, enum can_mode mode)
```

Set the controller to the given mode.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.
- `mode` – Operation mode

**Return values**

- 0 – If successful.
- -EIO – General input / output error, failed to configure device.

```
int can_set_timing(const struct device *dev, const struct can_timing *timing, const struct  
can_timing *timing_data)
```

Configure timing of a host controller.

If the `sjw` equals `CAN_SJW_NO_CHANGE`, the `sjw` parameter is not changed.

The second parameter `timing_data` is only relevant for CAN-FD. If the controller does not support CAN-FD or the FD mode is not enabled, this parameter is ignored.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.
- `timing` – Bus timings
- `timing_data` – Bus timings for data phase (CAN-FD only)

**Return values**

- 0 – If successful.
- -EIO – General input / output error, failed to configure device.

```
static inline int can_set_bitrate(const struct device *dev, uint32_t bitrate, uint32_t bitrate_data)
```

Set the bitrate of the CAN controller.

The second parameter `bitrate_data` is only relevant for CAN-FD. If the controller does not support CAN-FD or the FD mode is not enabled, this parameter is ignored. The sample point is set to the CiA DS 301 recommended value of 87.5%

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.
- `bitrate` – Desired arbitration phase bitrate
- `bitrate_data` – Desired data phase bitrate

**Return values**

- 0 – If successful.
- -EINVAL – bitrate cannot be reached.
- -EIO – General input / output error, failed to set bitrate.

```
static inline int can_configure(const struct device *dev, enum can_mode mode, uint32_t bitrate)
```

Configure operation of a host controller.

**Parameters**

- *dev* – Pointer to the device structure for the driver instance.
- *mode* – Operation mode
- *bitrate* – bus-speed in Baud/s

**Return values**

- 0 – If successful.
- -EIO – General input / output error, failed to configure device.

```
enum can_state can_get_state(const struct device *dev, struct can_bus_err_cnt *err_cnt)
```

Get current state.

Returns the actual state of the CAN controller.

**Parameters**

- *dev* – Pointer to the device structure for the driver instance.
- *err\_cnt* – Pointer to the *err\_cnt* destination structure or NULL.

**Return values** *state* –

```
int can_recover(const struct device *dev, k_timeout_t timeout)
```

Recover from bus-off state.

Recover the CAN controller from bus-off state to error-active state.

**Parameters**

- *dev* – Pointer to the device structure for the driver instance.
- *timeout* – Timeout for waiting for the recovery or K\_FOREVER.

**Return values**

- 0 – on success.
- CAN\_TIMEOUT – on timeout.

```
static inline void can_register_state_change_isr(const struct device *dev,  
                                                can_state_change_isr_t isr)
```

Register an ISR callback for state change interrupt.

Only one callback can be registered per controller. Calling this function again, overrides the previous call.

**Parameters**

- *dev* – Pointer to the device structure for the driver instance.
- *isr* – Pointer to ISR

```
static inline void can_copy_frame_to_zframe(const struct can_frame *frame, struct zcan_frame  
                                           *zframe)
```

Converter that translates between *can\_frame* and *zcan\_frame* structs.

**Parameters**

- *frame* – Pointer to *can\_frame* struct.
- *zframe* – Pointer to *zcan\_frame* struct.

```
static inline void can_copy_zframe_to_frame(const struct zcan_frame *zframe, struct can_frame
                                           *frame)
```

Converter that translates between *zcan\_frame* and *can\_frame* structs.

#### Parameters

- *zframe* – Pointer to *zcan\_frame* struct.
- *frame* – Pointer to *can\_frame* struct.

```
static inline void can_copy_filter_to_zfilter(const struct can_filter *filter, struct zcan_filter
                                              *zfilter)
```

Converter that translates between *can\_filter* and *zcan\_frame\_filter* structs.

#### Parameters

- *filter* – Pointer to *can\_filter* struct.
- *zfilter* – Pointer to *zcan\_frame\_filter* struct.

```
static inline void can_copy_zfilter_to_filter(const struct zcan_filter *zfilter, struct can_filter
                                              *filter)
```

Converter that translates between *zcan\_filter* and *can\_filter* structs.

#### Parameters

- *zfilter* – Pointer to *zcan\_filter* struct.
- *filter* – Pointer to *can\_filter* struct.

```
struct can_frame
```

*#include <can.h>* CAN frame structure that is compatible with Linux. This is mainly used by Socket CAN code.

Used to pass CAN messages from userspace to the socket CAN and vice versa.

#### Public Members

*canid\_t* *can\_id*

32 bit CAN\_ID + EFF/RTR/ERR flags

*uint8\_t* *can\_dlc*

The length of the message

*uint8\_t* *data*[8]

The message data

```
struct can_filter
```

*#include <can.h>* CAN filter that is compatible with Linux. This is mainly used by Socket CAN code.

A filter matches, when “received\_can\_id & mask == can\_id & mask”

```
struct zcan_frame
```

*#include <can.h>* CAN message structure.

Used to pass can messages from userspace to the driver and from driver to userspace

## Public Members

uint32\_t id

Message identifier

uint32\_t fd

Frame is in the CAN-FD frame format

uint32\_t rtr

Set the message to a transmission request instead of data frame use can\_rtr enum for assignment

uint32\_t id\_type

Indicates the identifier type (standard or extended) use can\_id enum for assignment

uint8\_t dlc

The length of the message (max. 8) in byte

uint8\_t brs

Baud Rate Switch. Frame transfer with different timing during the data phase. Only valid for CAN-FD

uint8\_t res

Reserved for future flags

union *zcan\_frame*.[anonymous] [anonymous]

The frame payload data.

struct zcan\_filter

*#include <can.h>* CAN filter structure.

Used to pass can identifier filter information to the driver. rtr\_mask and \*\_id\_mask are used to mask bits of the rtr and id fields. If the mask bit is 0, the value of the corresponding bit in the id or rtr field don't care for the filter matching.

## Public Members

uint32\_t id

target state of the identifier

uint32\_t rtr

target state of the rtr bit

uint32\_t id\_type

Indicates the identifier type (standard or extended) use can\_id enum for assignment

uint32\_t id\_mask

identifier mask

```
uint32_t rtr_mask
    rtr bit mask
```

```
struct can_bus_err_cnt
    #include <can.h> can bus error count structure
    Used to pass the bus error counters to userspace
```

```
struct can_timing
    #include <can.h> canbus timings

    Used to pass bus timing values to the config and bitrate calculator function.
```

The propagation segment represents the time of the signal propagation. Phase segment 1 and phase segment 2 define the sampling point. prop\_seg and phase\_seg1 affect the sampling-point in the same way and some controllers only have a register for the sum of those two. The sync segment always has a length of 1 tq + ————&#8212;+————&#8212;+————&#8212;+————&#8212;&#8212;+ |sync\_seg | prop\_seg | phase\_seg1 | phase\_seg2 | +————&#8212;+————&#8212;+————&#8212;+————&#8212;+————&#8212;+ ^

Sampling-Point 1 tq (time quantum) has the length of 1/(core\_clock / prescaler) The bitrate is defined by the core clock divided by the prescaler and the sum of the segments. br = (core\_clock / prescaler) / (1 + prop\_seg + phase\_seg1 + phase\_seg2) The resynchronization jump width (SJW) defines the amount of time quantum the sample point can be moved. The sample point is moved when resynchronization is needed.

## Public Members

uint16\_t sjw  
Synchronisation jump width

```
uint16_t prop_seg
    Propagation Segment
```

```
uint16_t phase_seg1
    Phase Segment 1
```

uint16\_t phase\_seg2  
Phase Segment 2

```
uint16_t prescaler
    Prescaler value
```

```
struct can_frame_buffer
    #include <can.h>
```

```
struct zcan_work
```

*#include <can.h>* CAN work structure.

Used to attach a work queue to a filter.

```
struct can_driver_api
    #include <can.h>
```

## ISO-TP Transport Protocol

- [Overview](#)
- [API Reference](#)

**Overview** ISO-TP is a transport protocol defined in the ISO-Standard ISO15765-2 Road vehicles - Diagnostic communication over Controller Area Network (DoCAN). Part2: Transport protocol and network layer services. As its name already implies, it is originally designed, and still used in road vehicle diagnostic over Controller Area Networks. Nevertheless, it's not limited to applications in road vehicles or the automotive domain.

This transport protocol extends the limited payload data size for classical CAN (8 bytes) and CAN-FD (64 bytes) to theoretically four gigabytes. Additionally, it adds a flow control mechanism to influence the sender's behavior. ISO-TP segments packets into small fragments depending on the payload size of the CAN frame. The header of those segments is called Protocol Control Information (PCI).

Packets smaller or equal to seven bytes on Classical CAN are called single-frames (SF). They don't need to fragment and do not have any flow-control.

Packets larger than that are segmented into a first-frame (FF) and as many consecutive-frames as required. The FF contains information about the length of the entire payload data and additionally, the first few bytes of payload data. The receiving peer sends back a flow-control-frame (FC) to either deny, postpone, or accept the following consecutive frames. The FC also defines the conditions of sending, namely the block-size (BS) and the minimum separation time between frames (STmin). The block size defines how many CF the sender is allowed to send, before he has to wait for another FC.

Figure 1: Example Sequence of a Segmented Packet with a BS of three

### Defines

`ISOTP_N_OK`

Completed successfully

`ISOTP_N_TIMEOUT_A`

Ar/As has timed out

`ISOTP_N_TIMEOUT_BS`

Reception of next FC has timed out

`ISOTP_N_TIMEOUT_CR`

Cr has timed out

ISOTP_N_WRONG_SN	Unexpected sequence number
ISOTP_N_INVALID_FS	Invalid flow status received
ISOTP_N_UNEXP_PDU	Unexpected PDU received
ISOTP_N_WFT_OVRN	Maximum number of WAIT flowStatus PDUs exceeded
ISOTP_N_BUFFER_OVERFLOW	FlowStatus OVFLW PDU was received
ISOTP_N_ERROR	General error
ISOTP_NO_FREE_FILTER	Implementation specific errors Can't bind or send because the CAN device has no filter left
ISOTP_NO_NET_BUF_LEFT	No net buffer left to allocate
ISOTP_NO_BUF_DATA_LEFT	Not sufficient space in the buffer left for the data
ISOTP_NO_CTX_LEFT	No context buffer left to allocate
ISOTP_RECV_TIMEOUT	Timeout for recv
ISOTP_FIXED_ADDR_SA_POS	Position of fixed source address (SA)
ISOTP_FIXED_ADDR_SA_MASK	Mask to obtain fixed source address (SA)
ISOTP_FIXED_ADDR_TA_POS	Position of fixed target address (TA)
ISOTP_FIXED_ADDR_TA_MASK	Mask to obtain fixed target address (TA)
ISOTP_FIXED_ADDR_PRIO_POS	Position of priority in fixed addressing mode

ISOTP\_FIXED\_ADDR\_PRIO\_MASK

Mask for priority in fixed addressing mode

ISOTP\_FIXED\_ADDR\_RX\_MASK

## Typedefs

```
typedef void (*isotp_tx_callback_t)(int error_nr, void *arg)
```

## Functions

```
int isotp_bind(struct isotp_rcv_ctx *ctx, const struct device *can_dev, const struct isotp_msg_id
               *rx_addr, const struct isotp_msg_id *tx_addr, const struct isotp_fc_opts *opts,
               k_timeout_t timeout)
```

Bind an address to a receiving context.

This function binds an RX and TX address combination to an RX context. When data arrives from the specified address, it is buffered and can be read by calling `isotp_rcv`. When calling this routine, a filter is applied in the CAN device, and the context is initialized. The context must be valid until calling `unbind`.

### Parameters

- `ctx` – Context to store the internal states.
- `can_dev` – The CAN device to be used for sending and receiving.
- `rx_addr` – Identifier for incoming data.
- `tx_addr` – Identifier for FC frames.
- `opts` – Flow control options.
- `timeout` – Timeout for FF SF buffer allocation.

### Return values

- `ISOTP_N_OK` – on success
- `ISOTP_NO_FREE_FILTER` – if CAN device has no filters left.

```
void isotp_unbind(struct isotp_rcv_ctx *ctx)
```

Unbind a context from the interface.

This function removes the binding from `isotp_bind`. The filter is detached from the CAN device, and if a transmission is ongoing, buffers are freed. The context can be discarded safely after calling this function.

### Parameters

- `ctx` – Context that should be unbound.

```
int isotp_rcv(struct isotp_rcv_ctx *ctx, uint8_t *data, size_t len, k_timeout_t timeout)
```

Read out received data from fifo.

This function reads the data from the receive FIFO of the context. It blocks if the FIFO is empty. If an error occurs, the function returns a negative number and leaves the data buffer unchanged.

### Parameters

- `ctx` – Context that is already bound.

- `data` – Pointer to a buffer where the data is copied to.
- `len` – Size of the buffer.
- `timeout` – Timeout for incoming data.

#### Return values

- Number – of bytes copied on success
- `ISOTP_WAIT_TIMEOUT` – when “timeout” timed out
- `ISOTP_N_*` – on error

```
int isotp_rcv_net(struct isotp_rcv_ctx *ctx, struct net\_buf **buffer, k\_timeout\_t timeout)
```

Get the net buffer on data reception.

This function reads incoming data into net-buffers. It blocks until the entire packet is received, BS is reached, or an error occurred. If BS was zero, the data is in a single [net\\_buf](#). Otherwise, the data is fragmented in chunks of BS size. The net-buffers are referenced and must be freed with `net_buf_unref` after the data is processed.

#### Parameters

- `ctx` – Context that is already bound.
- `buffer` – Pointer where the [net\\_buf](#) pointer is written to.
- `timeout` – Timeout for incoming data.

#### Return values

- Remaining – data length for this transfer if BS > 0, 0 for BS = 0
- `ISOTP_WAIT_TIMEOUT` – when “timeout” timed out
- `ISOTP_N_*` – on error

```
int isotp_send(struct isotp_send_ctx *ctx, const struct device *can_dev, const uint8_t *data,
              size_t len, const struct isotp\_msg\_id *tx_addr, const struct isotp\_msg\_id *rx_addr,
              isotp\_tx\_callback\_t complete_cb, void *cb_arg)
```

Send data.

This function is used to send data to a peer that listens to the `tx_addr`. An internal work-queue is used to transfer the segmented data. Data and context must be valid until the transmission has finished. If a `complete_cb` is given, this function is non-blocking, and the callback is called on completion with the return value as a parameter.

#### Parameters

- `ctx` – Context to store the internal states.
- `can_dev` – The CAN device to be used for sending and receiving.
- `data` – Data to be sent.
- `len` – Length of the data to be sent.
- `rx_addr` – Identifier for FC frames.
- `tx_addr` – Identifier for outgoing frames the receiver listens on.
- `complete_cb` – Function called on completion or NULL.
- `cb_arg` – Argument passed to the complete callback.

#### Return values

- `ISOTP_N_OK` – on success
- `ISOTP_N_*` – on error

struct isotp\_msg\_id

*#include <isotp.h>* ISO-TP message id struct.

Used to pass addresses to the bind and send functions.

### Public Members

union *isotp\_msg\_id*.[anonymous] [anonymous]

CAN identifier

If ISO-TP fixed addressing is used, isotp\_bind ignores SA and priority sections and modifies TA section in flow control frames.

uint8\_t ext\_addr

ISO-TP extended address (if used)

uint8\_t id\_type

Indicates the CAN identifier type (standard or extended)

uint8\_t use\_ext\_addr

Indicates if ISO-TP extended addressing is used

uint8\_t use\_fixed\_addr

Indicates if ISO-TP fixed addressing (acc. to SAE J1939) is used

struct isotp\_fc\_opts

*#include <isotp.h>* ISO-TP frame control options struct.

Used to pass the options to the bind and send functions.

### Public Members

uint8\_t bs

Block size. Number of CF PDUs before next CF is sent

uint8\_t stmin

Minimum separation time. Min time between frames

## 7.20.8 Generic GSM Modem

### Overview

The generic GSM modem driver allows the user to connect Zephyr to a GSM modem which provides a data connection to cellular operator's network. The Zephyr uses *PPP (Point-to-Point Protocol)* to connect to the GSM modem using UART. Note that some cellular modems have proprietary offloading support using AT commands, but usually those modems also support 3GPP standards and provide PPP connection to them. See GSM modem sample application how to setup Zephyr to use the GSM modem.

The GSM muxing, that is defined in *GSM 07.10*, and which allows mixing of AT commands and PPP traffic, is also supported in this version of Zephyr. One needs to enable `:kconfig: `CONFIG_GSM_MUX`` and `:kconfig: `CONFIG_UART_MUX`` configuration options to enable muxing.

## 7.21 Peripherals

### 7.21.1 ADC

#### Overview

#### API Reference

*group* `adc_interface`  
ADC driver APIs.

#### Typedefs

`typedef enum adc\_action (*adc_sequence_callback)(const struct device *dev, const struct adc\_sequence *sequence, uint16_t sampling_index)`

Type definition of the optional callback function to be called after a requested sampling is done.

**Param `dev`** Pointer to the device structure for the driver instance.

**Param `sequence`** Pointer to the sequence structure that triggered the sampling. This parameter points to a copy of the structure that was supplied to the call that started the sampling sequence, thus it cannot be used with the [CONTAINER\\_OF\(\)](#) macro to retrieve some other data associated with the sequence. Instead, the [adc\\_sequence\\_options::user\\_data](#) field should be used for such purpose.

**Param `sampling_index`** Index (0-65535) of the sampling done.

**Return** Action to be performed by the driver. See [adc\\_action](#).

`typedef int (*adc_api_channel_setup)(const struct device *dev, const struct adc\_channel\_cfg *channel_cfg)`

Type definition of ADC API function for configuring a channel. See [adc\\_channel\\_setup\(\)](#) for argument descriptions.

`typedef int (*adc_api_read)(const struct device *dev, const struct adc\_sequence *sequence)`

Type definition of ADC API function for setting a read request. See [adc\\_read\(\)](#) for argument descriptions.

`typedef int (*adc_api_read_async)(const struct device *dev, const struct adc\_sequence *sequence, struct k\_poll\_signal *async)`

Type definition of ADC API function for setting an asynchronous read request. See [adc\\_read\\_async\(\)](#) for argument descriptions.

#### Enums

`enum adc_gain`  
ADC channel gain factors.

*Values:*

enumerator `ADC_GAIN_1_6`  
x 1/6.

enumerator ADC\_GAIN\_1\_5  
x 1/5.

enumerator ADC\_GAIN\_1\_4  
x 1/4.

enumerator ADC\_GAIN\_1\_3  
x 1/3.

enumerator ADC\_GAIN\_1\_2  
x 1/2.

enumerator ADC\_GAIN\_2\_3  
x 2/3.

enumerator ADC\_GAIN\_1  
x 1.

enumerator ADC\_GAIN\_2  
x 2.

enumerator ADC\_GAIN\_3  
x 3.

enumerator ADC\_GAIN\_4  
x 4.

enumerator ADC\_GAIN\_6  
x 6.

enumerator ADC\_GAIN\_8  
x 8.

enumerator ADC\_GAIN\_12  
x 12.

enumerator ADC\_GAIN\_16  
x 16.

enumerator ADC\_GAIN\_24  
x 24.

enumerator ADC\_GAIN\_32  
x 32.

enumerator ADC\_GAIN\_64  
x 64.

enumerator ADC\_GAIN\_128  
x 128.

enum adc\_reference  
ADC references.  
*Values:*

enumerator ADC\_REF\_VDD\_1  
VDD.

enumerator ADC\_REF\_VDD\_1\_2  
VDD/2.

enumerator ADC\_REF\_VDD\_1\_3  
VDD/3.

enumerator ADC\_REF\_VDD\_1\_4  
VDD/4.

enumerator ADC\_REF\_INTERNAL  
Internal.

enumerator ADC\_REF\_EXTERNAL0  
External, input 0.

enumerator ADC\_REF\_EXTERNAL1  
External, input 1.

enum adc\_action  
Action to be performed after a sampling is done.  
*Values:*

enumerator ADC\_ACTION\_CONTINUE = 0  
The sequence should be continued normally.

enumerator ADC\_ACTION\_REPEAT  
The sampling should be repeated. New samples or sample should be read from the ADC and written in the same place as the recent ones.

enumerator ADC\_ACTION\_FINISH  
The sequence should be finished immediately.

## Functions

int adc\_gain\_invert(enum [adc\\_gain](#) gain, int32\_t \*value)  
Invert the application of gain to a measurement value.

For example, if the gain passed in is ADC\_GAIN\_1\_6 and the referenced value is 10, the value after the function returns is 60.

**Parameters**

- `gain` – the gain used to amplify the input signal.
- `value` – a pointer to a value that initially has the effect of the applied gain but has that effect removed when this function successfully returns. If the gain cannot be reversed the value remains unchanged.

**Return values**

- 0 – if the gain was successfully reversed
- `-EINVAL` – if the gain could not be interpreted

```
static inline int adc_raw_to_millivolts(int32_t ref_mv, enum adc\_gain gain, uint8_t resolution,  
                                     int32_t *valp)
```

Convert a raw ADC value to millivolts.

This function performs the necessary conversion to transform a raw ADC measurement to a voltage in millivolts.

**Parameters**

- `ref_mv` – the reference voltage used for the measurement, in millivolts. This may be from [adc\\_ref\\_internal\(\)](#) or a known external reference.
- `gain` – the ADC gain configuration used to sample the input
- `resolution` – the number of bits in the absolute value of the sample. For differential sampling this may be one less than the resolution in struct [adc\\_sequence](#).
- `valp` – pointer to the raw measurement value on input, and the corresponding millivolt value on successful conversion. If conversion fails the stored value is left unchanged.

**Return values**

- 0 – on successful conversion
- `-EINVAL` – if the gain is not reversible

```
int adc_channel_setup(const struct device *dev, const struct adc\_channel\_cfg *channel_cfg)
```

Configure an ADC channel.

It is required to call this function and configure each channel before it is selected for a read request.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.
- `channel_cfg` – Channel configuration.

**Return values**

- 0 – On success.
- `-EINVAL` – If a parameter with an invalid value has been provided.

```
int adc_read(const struct device *dev, const struct adc\_sequence *sequence)
```

Set a read request.

If invoked from user mode, any sequence struct options for callback must be NULL.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.
- `sequence` – Structure specifying requested sequence of samplings.

### Return values

- 0 – On success.
- -EINVAL – If a parameter with an invalid value has been provided.
- -ENOMEM – If the provided buffer is too small to hold the results of all requested samplings.
- -ENOTSUP – If the requested mode of operation is not supported.
- -EBUSY – If another sampling was triggered while the previous one was still in progress. This may occur only when samplings are done with intervals, and it indicates that the selected interval was too small. All requested samples are written in the buffer, but at least some of them were taken with an extra delay compared to what was scheduled.

```
int adc_read_async(const struct device *dev, const struct adc_sequence *sequence, struct k_poll_signal *async)
```

Set an asynchronous read request.

If invoked from user mode, any sequence struct options for callback must be NULL.

---

**Note:** This function is available only if `:kconfig: `CONFIG_ADC_ASYNC`` is selected.

---

### Parameters

- dev – Pointer to the device structure for the driver instance.
- sequence – Structure specifying requested sequence of samplings.
- async – Pointer to a valid and ready to be signaled struct *k\_poll\_signal*. (Note: if NULL this function will not notify the end of the transaction, and whether it went successfully or not).

**Returns** 0 on success, negative error code otherwise. See *adc\_read()* for a list of possible error codes.

```
static inline uint16_t adc_ref_internal(const struct device *dev)
```

Get the internal reference voltage.

Returns the voltage corresponding to *ADC\_REF\_INTERNAL*, measured in millivolts.

**Returns** a positive value is the reference voltage value. Returns zero if reference voltage information is not available.

```
struct adc_channel_cfg
```

*#include <adc.h>* Structure for specifying the configuration of an ADC channel.

### Public Members

```
enum adc_gain gain
```

Gain selection.

```
enum adc_reference reference
```

Reference selection.

`uint16_t acquisition_time`

Acquisition time. Use the `ADC_ACQ_TIME` macro to compose the value for this field or pass `ADC_ACQ_TIME_DEFAULT` to use the default setting for a given hardware (e.g. when the hardware does not allow to configure the acquisition time). Particular drivers do not necessarily support all the possible units. Value range is 0-16383 for a given unit.

`uint8_t channel_id`

Channel identifier. This value primarily identifies the channel within the ADC API - when a read request is done, the corresponding bit in the “channels” field of the “`adc_sequence`” structure must be set to include this channel in the sampling. For hardware that does not allow selection of analog inputs for given channels, but rather have dedicated ones, this value also selects the physical ADC input to be used in the sampling. Otherwise, when it is needed to explicitly select an analog input for the channel, or two inputs when the channel is a differential one, the selection is done in “`input_positive`” and “`input_negative`” fields. Particular drivers indicate which one of the above two cases they support by selecting or not a special hidden Kconfig option named `ADC_CONFIGURABLE_INPUTS`. If this option is not selected, the macro `CONFIG_ADC_CONFIGURABLE_INPUTS` is not defined and consequently the mentioned two fields are not present in this structure. While this API allows identifiers from range 0-31, particular drivers may support only a limited number of channel identifiers (dependent on the underlying hardware capabilities or configured via a dedicated Kconfig option).

`uint8_t differential`

Channel type: single-ended or differential.

`struct adc_sequence_options`

*#include <adc.h>* Structure defining additional options for an ADC sampling sequence.

## Public Members

`uint32_t interval_us`

Interval between consecutive samplings (in microseconds), 0 means sample as fast as possible, without involving any timer. The accuracy of this interval is dependent on the implementation of a given driver. The default routine that handles the intervals uses a kernel timer for this purpose, thus, it has the accuracy of the kernel’s system clock. Particular drivers may use some dedicated hardware timers and achieve a better precision.

*[adc\\_sequence\\_callback](#)* callback

Callback function to be called after each sampling is done. Optional - set to NULL if it is not needed.

`void *user_data`

Pointer to user data. It can be used to associate the sequence with any other data that is needed in the callback function.

`uint16_t extra_samplings`

Number of extra samplings to perform (the total number of samplings is 1 + `extra_samplings`).

`struct adc_sequence`

*#include <adc.h>* Structure defining an ADC sampling sequence.

## Public Members

const struct [adc\\_sequence\\_options](#) \*options

Pointer to a structure defining additional options for the sequence. If NULL, the sequence consists of a single sampling.

uint32\_t channels

Bit-mask indicating the channels to be included in each sampling of this sequence. All selected channels must be configured with [adc\\_channel\\_setup\(\)](#) before they are used in a sequence.

void \*buffer

Pointer to a buffer where the samples are to be written. Samples from subsequent samplings are written sequentially in the buffer. The number of samples written for each sampling is determined by the number of channels selected in the “channels” field. The buffer must be of an appropriate size, taking into account the number of selected channels and the ADC resolution used, as well as the number of samplings contained in the sequence.

size\_t buffer\_size

Specifies the actual size of the buffer pointed by the “buffer” field (in bytes). The driver must ensure that samples are not written beyond the limit and it must return an error if the buffer turns out to be not large enough to hold all the requested samples.

uint8\_t resolution

ADC resolution. For single-ended channels the sample values are from range:  $0 \dots 2^{\text{resolution}} - 1$ , for differential ones:

- $2^{(\text{resolution}-1)} \dots 2^{(\text{resolution}-1)} - 1$ .

uint8\_t oversampling

Oversampling setting. Each sample is averaged from  $2^{\text{oversampling}}$  conversion results. This feature may be unsupported by a given ADC hardware, or in a specific mode (e.g. when sampling multiple channels).

bool calibrate

Perform calibration before the reading is taken if requested.

The impact of channel configuration on the calibration process is specific to the underlying hardware. ADC implementations that do not support calibration should ignore this flag.

struct [adc\\_driver\\_api](#)

*#include <adc.h>* ADC driver API.

This is the mandatory API any ADC driver needs to expose.

## 7.21.2 Counter

### Overview

### API Reference

group [counter\\_interface](#)

Counter Interface.

## Typedefs

```
typedef void (*counter_alarm_callback_t)(const struct device *dev, uint8_t chan_id, uint32_t ticks, void *user_data)
```

Alarm callback.

**Param dev** Pointer to the device structure for the driver instance.

**Param chan\_id** Channel ID.

**Param ticks** Counter value that triggered the alarm.

**Param user\_data** User data.

```
typedef void (*counter_top_callback_t)(const struct device *dev, void *user_data)
```

Callback called when counter turns around.

**Param dev** Pointer to the device structure for the driver instance.

**Param user\_data** User data provided in *counter\_set\_top\_value*.

```
typedef int (*counter_api_start)(const struct device *dev)
```

```
typedef int (*counter_api_stop)(const struct device *dev)
```

```
typedef int (*counter_api_get_value)(const struct device *dev, uint32_t *ticks)
```

```
typedef int (*counter_api_set_alarm)(const struct device *dev, uint8_t chan_id, const struct counter_alarm_cfg *alarm_cfg)
```

```
typedef int (*counter_api_cancel_alarm)(const struct device *dev, uint8_t chan_id)
```

```
typedef int (*counter_api_set_top_value)(const struct device *dev, const struct counter_top_cfg *cfg)
```

```
typedef uint32_t (*counter_api_get_pending_int)(const struct device *dev)
```

```
typedef uint32_t (*counter_api_get_top_value)(const struct device *dev)
```

```
typedef uint32_t (*counter_api_get_guard_period)(const struct device *dev, uint32_t flags)
```

```
typedef int (*counter_api_set_guard_period)(const struct device *dev, uint32_t ticks, uint32_t flags)
```

## Functions

```
bool counter_is_counting_up(const struct device *dev)
```

Function to check if counter is counting up.

### Parameters

- **dev** – [in] Pointer to the device structure for the driver instance.

### Return values

- **true** – if counter is counting up.

- `false` – if counter is counting down.

`uint8_t counter_get_num_of_channels(const struct device *dev)`

Function to get number of alarm channels.

**Parameters**

- `dev` – **[in]** Pointer to the device structure for the driver instance.

**Returns** Number of alarm channels.

`uint32_t counter_get_frequency(const struct device *dev)`

Function to get counter frequency.

**Parameters**

- `dev` – **[in]** Pointer to the device structure for the driver instance.

**Returns** Frequency of the counter in Hz, or zero if the counter does not have a fixed frequency.

`uint32_t counter_us_to_ticks(const struct device *dev, uint64_t us)`

Function to convert microseconds to ticks.

**Parameters**

- `dev` – **[in]** Pointer to the device structure for the driver instance.
- `us` – **[in]** Microseconds.

**Returns** Converted ticks. Ticks will be saturated if exceed 32 bits.

`uint64_t counter_ticks_to_us(const struct device *dev, uint32_t ticks)`

Function to convert ticks to microseconds.

**Parameters**

- `dev` – **[in]** Pointer to the device structure for the driver instance.
- `ticks` – **[in]** Ticks.

**Returns** Converted microseconds.

`uint32_t counter_get_max_top_value(const struct device *dev)`

Function to retrieve maximum top value that can be set.

**Parameters**

- `dev` – **[in]** Pointer to the device structure for the driver instance.

**Returns** Max top value.

`int counter_start(const struct device *dev)`

Start counter device in free running mode.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.

**Return values**

- 0 – If successful.
- Negative – `errno` code if failure.

`int counter_stop(const struct device *dev)`

Stop counter device.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.

**Return values**

- 0 – If successful.
- -ENOTSUP – if the device doesn't support stopping the counter.

```
int counter_get_value(const struct device *dev, uint32_t *ticks)
```

Get current counter value.

**Parameters**

- dev – Pointer to the device structure for the driver instance.
- ticks – Pointer to where to store the current counter value

**Return values**

- 0 – If successful.
- Negative – error code on failure getting the counter value

```
int counter_set_channel_alarm(const struct device *dev, uint8_t chan_id, const struct  
                             counter_alarm_cfg *alarm_cfg)
```

Set a single shot alarm on a channel.

After expiration alarm can be set again, disabling is not needed. When alarm expiration handler is called, channel is considered available and can be set again in that context.

---

**Note:** API is not thread safe.

---

**Parameters**

- dev – Pointer to the device structure for the driver instance.
- chan\_id – Channel ID.
- alarm\_cfg – Alarm configuration.

**Return values**

- 0 – If successful.
- -ENOTSUP – if request is not supported (device does not support interrupts or requested channel).
- -EINVAL – if alarm settings are invalid.
- -ETIME – if absolute alarm was set too late.

```
int counter_cancel_channel_alarm(const struct device *dev, uint8_t chan_id)
```

Cancel an alarm on a channel.

---

**Note:** API is not thread safe.

---

**Parameters**

- dev – Pointer to the device structure for the driver instance.
- chan\_id – Channel ID.

**Return values**

- 0 – If successful.
- -ENOTSUP – if request is not supported or the counter was not started yet.

```
int counter_set_top_value(const struct device *dev, const struct counter_top_cfg *cfg)
```

Set counter top value.

Function sets top value and optionally resets the counter to 0 or top value depending on counter direction. On turnaround, counter can be reset and optional callback is periodically called. Top value can only be changed when there is no active channel alarm.

COUNTER\_TOP\_CFG\_DONT\_RESET prevents counter reset. When counter is running while top value is updated, it is possible that counter progresses outside the new top value. In that case, error is returned and optionally driver can reset the counter (see COUNTER\_TOP\_CFG\_RESET\_WHEN\_LATE).

#### Parameters

- *dev* – Pointer to the device structure for the driver instance.
- *cfg* – Configuration. Cannot be NULL.

#### Return values

- 0 – If successful.
- -ENOTSUP – if request is not supported (e.g. top value cannot be changed or counter cannot/must be reset during top value update).
- -EBUSY – if any alarm is active.
- -ETIME – if COUNTER\_TOP\_CFG\_DONT\_RESET was set and new top value is smaller than current counter value (counter counting up).

```
int counter_get_pending_int(const struct device *dev)
```

Function to get pending interrupts.

The purpose of this function is to return the interrupt status register for the device. This is especially useful when waking up from low power states to check the wake up source.

#### Parameters

- *dev* – Pointer to the device structure for the driver instance.

#### Return values

- 1 – if any counter interrupt is pending.
- 0 – if no counter interrupt is pending.

```
uint32_t counter_get_top_value(const struct device *dev)
```

Function to retrieve current top value.

#### Parameters

- *dev* – **[in]** Pointer to the device structure for the driver instance.

**Returns** Top value.

```
int counter_set_guard_period(const struct device *dev, uint32_t ticks, uint32_t flags)
```

Set guard period in counter ticks.

Setting non-zero guard period enables detection of setting absolute alarm too late. It limits how far in the future absolute alarm can be set.

Detection of too late setting is vital since if it is not detected alarm is delayed by full period of the counter (up to 32 bits). Because of the wrapping, it is impossible to distinguish alarm which is short in the past from alarm which is targeted to expire after full counter period. In order to detect too late setting, longest possible alarm is limited. Absolute value cannot exceed:  $(\text{now} + \text{top\_value} - \text{guard\_period}) \% \text{top\_value}$ .

Guard period depends on application and counter frequency. If it is expected that absolute alarms setting might be delayed then guard period should exceed maximal potential delay. If use case allows, guard period can be set very high (e.g. half of the counter top value).

After initialization guard period is set to 0 and late detection is disabled.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.
- `ticks` – Guard period in counter ticks.
- `flags` – See Counter guard period flags.

**Return values**

- 0 – if successful.
- `-ENOTSUP` – if function or flags are not supported.
- `-EINVAL` – if ticks value is invalid.

`uint32_t counter_get_guard_period(const struct device *dev, uint32_t flags)`

Return guard period.

See [counter\\_set\\_guard\\_period](#).

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.
- `flags` – See Counter guard period flags.

**Returns** Guard period given in counter ticks or 0 if function or flags are not supported.

`struct counter_alarm_cfg`

*#include <counter.h>* Alarm callback structure.

**Param callback** Callback called on alarm (cannot be NULL).

**Param ticks** Number of ticks that triggers the alarm. It can be relative (to now) or absolute value (see `COUNTER_ALARM_CFG_ABSOLUTE`). Absolute alarm cannot be set further in future than `top_value` decremented by the guard period. Relative alarm ticks cannot exceed current top value (see [counter\\_get\\_top\\_value](#)). If counter is clock driven then ticks can be converted to microseconds (see [counter\\_ticks\\_to\\_us](#)). Alternatively, counter implementation may count asynchronous events.

**Param user\_data** User data returned in callback.

**Param flags** Alarm flags. See Alarm configuration flags.

`struct counter_top_cfg`

*#include <counter.h>* Top value configuration structure.

**Param ticks** Top value.

**Param callback** Callback function. Can be NULL.

**Param user\_data** User data passed to callback function. Not valid if callback is NULL.

**Param flags** Flags. See Flags used by .

`struct counter_config_info`

*#include <counter.h>* Structure with generic counter features.

**Param max\_top\_value** Maximal (default) top value on which counter is reset (cleared or reloaded).

**Param freq** Frequency of the source clock if synchronous events are counted.

**Param flags** Flags. See Counter device capabilities.

**Param channels** Number of channels that can be used for setting alarm, see [counter\\_set\\_channel\\_alarm](#).

```
struct counter_driver_api
#include <counter.h>
```

### 7.21.3 Clock Control

#### Overview

The clock control API provides access to clocks in the system, including the ability to turn them on and off.

#### Configuration Options

Related configuration options:

- **`:kconfig: `CONFIG_CLOCK_CONTROL``**

#### API Reference

*group* clock\_control\_interface  
Clock Control Interface.

#### Defines

CLOCK\_CONTROL\_SUBSYS\_ALL

#### Typedefs

```
typedef void *clock_control_subsys_t
```

clock\_control\_subsys\_t is a type to identify a clock controller sub-system. Such data pointed is opaque and relevant only to the clock controller driver instance being used.

```
typedef void (*clock_control_cb_t)(const struct device *dev, clock\_control\_subsys\_t subsys, void *user_data)
```

Callback called on clock started.

**Param dev** Device structure whose driver controls the clock.

**Param subsys** Opaque data representing the clock.

**Param user\_data** User data.

```
typedef int (*clock_control)(const struct device *dev, clock\_control\_subsys\_t sys)
```

```
typedef int (*clock_control_get)(const struct device *dev, clock\_control\_subsys\_t sys, uint32_t *rate)
```

```
typedef int (*clock_control_async_on_fn)(const struct device *dev, clock_control_subsys_t sys,  
clock_control_cb_t cb, void *user_data)
```

```
typedef enum clock_control_status (*clock_control_get_status_fn)(const struct device *dev,  
clock_control_subsys_t sys)
```

## Enums

```
enum clock_control_status
```

Current clock status.

*Values:*

```
enumerator CLOCK_CONTROL_STATUS_STARTING
```

```
enumerator CLOCK_CONTROL_STATUS_OFF
```

```
enumerator CLOCK_CONTROL_STATUS_ON
```

```
enumerator CLOCK_CONTROL_STATUS_UNAVAILABLE
```

```
enumerator CLOCK_CONTROL_STATUS_UNKNOWN
```

## Functions

```
static inline int clock_control_on(const struct device *dev, clock_control_subsys_t sys)
```

Enable a clock controlled by the device.

On success, the clock is enabled and ready when this function returns. This function may sleep, and thus can only be called from thread context.

Use *clock\_control\_async\_on()* for non-blocking operation.

### Parameters

- *dev* – Device structure whose driver controls the clock.
- *sys* – Opaque data representing the clock.

**Returns** 0 on success, negative *errno* on failure.

```
static inline int clock_control_off(const struct device *dev, clock_control_subsys_t sys)
```

Disable a clock controlled by the device.

This function is non-blocking and can be called from any context. On success, the clock is disabled when this function returns.

### Parameters

- *dev* – Device structure whose driver controls the clock
- *sys* – Opaque data representing the clock

**Returns** 0 on success, negative *errno* on failure.

```
static inline int clock_control_async_on(const struct device *dev, clock_control_subsys_t sys,  
                                       clock_control_cb_t cb, void *user_data)
```

Request clock to start with notification when clock has been started.

Function is non-blocking and can be called from any context. User callback is called when clock is started.

#### Parameters

- dev – Device.
- sys – A pointer to an opaque data representing the sub-system.
- cb – Callback.
- user\_data – User context passed to the callback.

#### Return values

- 0 – if start is successfully initiated.
- -EALREADY – if clock was already started and is starting or running.
- -ENOTSUP – If the requested mode of operation is not supported.
- -ENOSYS – if the interface is not implemented.
- other – negative errno on vendor specific error.

```
static inline enum clock_control_status clock_control_get_status(const struct device *dev,  
                                                                clock_control_subsys_t sys)
```

Get clock status.

#### Parameters

- dev – Device.
- sys – A pointer to an opaque data representing the sub-system.

**Returns** Status.

```
static inline int clock_control_get_rate(const struct device *dev, clock_control_subsys_t sys,  
                                       uint32_t *rate)
```

Obtain the clock rate of given sub-system.

#### Parameters

- dev – Pointer to the device structure for the clock controller driver instance
- sys – A pointer to an opaque data representing the sub-system
- rate – **[out]** Subsystem clock rate

```
struct clock_control_driver_api  
#include <clock_control.h>
```

## 7.21.4 DAC

### Overview

The DAC API provides access to Digital-to-Analog Converter (DAC) devices.

## Configuration Options

Related configuration options:

- `:kconfig: `CONFIG_DAC``

## API Reference

*group* `dac_interface`

DAC driver APIs.

### Functions

`int dac_channel_setup(const struct device *dev, const struct dac_channel_cfg *channel_cfg)`

Configure a DAC channel.

It is required to call this function and configure each channel before it is selected for a write request.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `channel_cfg` – Channel configuration.

#### Return values

- 0 – On success.
- -EINVAL – If a parameter with an invalid value has been provided.
- -ENOTSUP – If the requested resolution is not supported.

`int dac_write_value(const struct device *dev, uint8_t channel, uint32_t value)`

Write a single value to a DAC channel.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `channel` – Number of the channel to be used.
- `value` – Data to be written to DAC output registers.

#### Return values

- 0 – On success.
- -EINVAL – If a parameter with an invalid value has been provided.

`struct dac_channel_cfg`

*#include <dac.h>* Structure for specifying the configuration of a DAC channel.

**Param `channel_id`** Channel identifier of the DAC that should be configured.

**Param `resolution`** Desired resolution of the DAC (depends on device capabilities).

## 7.21.5 DMA

### Overview

### API Reference

group dma\_interface

DMA Interface.

## Defines

DMA\_MAGIC

## Typedefs

typedef void (\*dma\_callback\_t)(const struct *device* \*dev, void \*user\_data, uint32\_t channel, int status)

Callback function for DMA transfer completion.

If enabled, callback function will be invoked at transfer completion or when error happens.

**Param dev** Pointer to the DMA device calling the callback.

**Param user\_data** A pointer to some user data or NULL

**Param channel** The channel number

**Param status** 0 on success, a negative errno otherwise

## Enums

enum dma\_channel\_direction

*Values:*

enumerator MEMORY\_TO\_MEMORY = 0x0

enumerator MEMORY\_TO\_PERIPHERAL

enumerator PERIPHERAL\_TO\_MEMORY

enumerator PERIPHERAL\_TO\_PERIPHERAL

enum dma\_addr\_adj

Valid values for *source\_addr\_adj* and *dest\_addr\_adj*

*Values:*

enumerator DMA\_ADDR\_ADJ\_INCREMENT

enumerator DMA\_ADDR\_ADJ\_DECREMENT

enumerator DMA\_ADDR\_ADJ\_NO\_CHANGE

enum dma\_channel\_filter

*Values:*

enumerator DMA\_CHANNEL\_NORMAL

enumerator DMA\_CHANNEL\_PERIODIC

## Functions

static inline int dma\_config(const struct [device](#) \*dev, uint32\_t channel, struct [dma\\_config](#) \*config)

Configure individual channel for DMA transfer.

### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `channel` – Numeric identification of the channel to configure
- `config` – Data structure containing the intended configuration for the selected channel

### Return values

- 0 – if successful.
- Negative – errno code if failure.

static inline int dma\_reload(const struct [device](#) \*dev, uint32\_t channel, uint32\_t src, uint32\_t dst, size\_t size)

Reload buffer(s) for a DMA channel.

### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `channel` – Numeric identification of the channel to configure selected channel
- `src` – source address for the DMA transfer
- `dst` – destination address for the DMA transfer
- `size` – size of DMA transfer

### Return values

- 0 – if successful.
- Negative – errno code if failure.

int dma\_start(const struct [device](#) \*dev, uint32\_t channel)

Enables DMA channel and starts the transfer, the channel must be configured beforehand.

Implementations must check the validity of the channel ID passed in and return -EINVAL if it is invalid.

### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `channel` – Numeric identification of the channel where the transfer will be processed

### Return values

- 0 – if successful.
- Negative – errno code if failure.

```
int dma_stop(const struct device *dev, uint32_t channel)
```

Stops the DMA transfer and disables the channel.

Implementations must check the validity of the channel ID passed in and return -EINVAL if it is invalid.

#### Parameters

- *dev* – Pointer to the device structure for the driver instance.
- *channel* – Numeric identification of the channel where the transfer was being processed

#### Return values

- 0 – if successful.
- Negative – errno code if failure.

```
int dma_request_channel(const struct device *dev, void *filter_param)
```

request DMA channel.

request DMA channel resources return -EINVAL if there is no valid channel available.

#### Parameters

- *dev* – Pointer to the device structure for the driver instance.
- *filter\_param* – filter function parameter

#### Return values

- *dma* – channel if successful.
- Negative – errno code if failure.

```
void dma_release_channel(const struct device *dev, uint32_t channel)
```

release DMA channel.

release DMA channel resources

#### Parameters

- *dev* – Pointer to the device structure for the driver instance.
- *channel* – channel number

```
int dma_chan_filter(const struct device *dev, int channel, void *filter_param)
```

DMA channel filter.

filter channel by attribute

#### Parameters

- *dev* – Pointer to the device structure for the driver instance.
- *channel* – channel number
- *filter\_param* – filter attribute

**Return values** Negative – errno code if not support

```
static inline int dma_get_status(const struct device *dev, uint32_t channel, struct dma_status *stat)
```

get current runtime status of DMA transfer

Implementations must check the validity of the channel ID passed in and return -EINVAL if it is invalid or -ENOSYS if not supported.

#### Parameters

- *dev* – Pointer to the device structure for the driver instance.

- `channel` – Numeric identification of the channel where the transfer was being processed
- `stat` – a non-NULL [dma\\_status](#) object for storing DMA status

#### Return values

- non-negative – if successful.
- Negative – errno code if failure.

```
static inline uint32_t dma_width_index(uint32_t size)
```

Look-up generic width index to be used in registers.

WARNING: This look-up works for most controllers, but *may* not work for yours. Ensure your controller expects the most common register bit values before using this convenience function. If your controller does not support these values, you will have to write your own look-up inside the controller driver.

#### Parameters

- `size` – width of bus (in bytes)

**Return values** `common` – DMA index to be placed into registers.

```
static inline uint32_t dma_burst_index(uint32_t burst)
```

Look-up generic burst index to be used in registers.

WARNING: This look-up works for most controllers, but *may* not work for yours. Ensure your controller expects the most common register bit values before using this convenience function. If your controller does not support these values, you will have to write your own look-up inside the controller driver.

#### Parameters

- `burst` – number of bytes to be sent in a single burst

**Return values** `common` – DMA index to be placed into registers.

```
struct dma_block_config
```

*#include <dma.h>* DMA block configuration structure.

**Param** `source_address` is block starting address at source

**Param** `source_gather_interval` is the address adjustment at gather boundary

**Param** `dest_address` is block starting address at destination

**Param** `dest_scatter_interval` is the address adjustment at scatter boundary

**Param** `dest_scatter_count` is the continuous transfer count between scatter boundaries

**Param** `source_gather_count` is the continuous transfer count between gather boundaries

**Param** `block_size` is the number of bytes to be transferred for this block.

**Param** `config` is a bit field with the following parts:

<code>source_gather_en</code>	[ 0 ]	- 0-disable, 1-enable.
<code>dest_scatter_en</code>	[ 1 ]	- 0-disable, 1-enable.
<code>source_addr_adj</code>	[ 2 : 3 ]	- 00-increment, 01-decrement, 10-no change.
<code>dest_addr_adj</code>	[ 4 : 5 ]	- 00-increment, 01-decrement, 10-no change.
<code>source_reload_en</code>	[ 6 ]	- reload source address at the end
↪ of		

(continues on next page)

(continued from previous page)

```

                                block transfer
                                0-disable, 1-enable.
dest_reload_en    [ 7 ]      - reload destination address at
↪the end

                                of block transfer
                                0-disable, 1-enable.
fifo_mode_control [ 8 : 11 ] - How full of the fifo before
↪transfer

                                start. HW specific.
flow_control_mode [ 12 ]     - 0-source request served upon data
                                availability.
                                1-source request postponed until
                                destination request happens.
reserved          [ 13 : 15 ]

```

```
struct dma_config
```

```
#include <dma.h> DMA configuration structure.
```

**Param dma\_slot** [ 0 : 6 ] - which peripheral and direction (HW specific)

**Param channel\_direction** [ 7 : 9 ] - 000-memory to memory, 001-memory to peripheral, 010-peripheral to memory, 011-peripheral to peripheral, ...

**Param complete\_callback\_en** [ 10 ] - 0-callback invoked at completion only 1-callback invoked at completion of each block

**Param error\_callback\_en** [ 11 ] - 0-error callback enabled 1-error callback disabled

**Param source\_handshake** [ 12 ] - 0-HW, 1-SW

**Param dest\_handshake** [ 13 ] - 0-HW, 1-SW

**Param channel\_priority** [ 14 : 17 ] - DMA channel priority

**Param source\_chaining\_en** [ 18 ] - enable/disable source block chaining 0-disable, 1-enable

**Param dest\_chaining\_en** [ 19 ] - enable/disable destination block chaining. 0-disable, 1-enable

**Param linked\_channel** [ 20 : 26 ] - after channel count exhaust will initiate a channel service request at this channel

**Param reserved** [ 27 : 31 ]

**Param source\_data\_size** [ 0 : 15 ] - width of source data (in bytes)

**Param dest\_data\_size** [ 16 : 31 ] - width of dest data (in bytes)

**Param source\_burst\_length** [ 0 : 15 ] - number of source data units

**Param dest\_burst\_length** [ 16 : 31 ] - number of destination data units

**Param block\_count** is the number of blocks used for block chaining, this depends on availability of the DMA controller.

**Param user\_data** private data from DMA client.

**Param dma\_callback** see `dma_callback_t` for details

```
struct dma_status
```

```
#include <dma.h> DMA runtime status structure
```

**busy** - is current DMA transfer busy or idle **dir** - DMA transfer direction **pending\_length** - data length pending to be transferred in bytes or platform dependent.

```
struct dma_context
```

*#include <dma.h>* DMA context structure Note: the *dma\_context* shall be the first member of DMA client driver Data, got by *dev->data*

magic - magic code to identify the context  
dma\_channels - dma channels  
atomic - driver atomic\_t pointer

## 7.21.6 EC Host Command

### Overview

### API Reference

group ec\_host\_cmd\_periph\_interface

EC Host Command Interface.

### Defines

EC\_HOST\_CMD\_HANDLER(\_function, \_id, \_version\_mask, \_request\_type, \_response\_type)

Statically define and register a host command handler.

Helper macro to statically define and register a host command handler that has a compile-time-fixed sizes for its both request and response structures.

#### Parameters

- *\_function* – Name of handler function.
- *\_id* – Id of host command to handle request for.
- *\_version\_mask* – The bitfield of all versions that the *\_function* supports. E.g. *BIT(0)* correspond to version 0.
- *\_request\_type* – The datatype of the request parameters for *\_function*.
- *\_response\_type* – The datatype of the response parameters for *\_function*.

EC\_HOST\_CMD\_HANDLER\_UNBOUND(\_function, \_id, \_version\_mask)

Statically define and register a host command handler without sizes.

Helper macro to statically define and register a host command handler whose request or response structure size is not known as compile time.

#### Parameters

- *\_function* – Name of handler function.
- *\_id* – Id of host command to handle request for.
- *\_version\_mask* – The bitfield of all versions that the *\_function* supports. E.g. *BIT(0)* correspond to version 0.

### Typedefs

```
typedef enum ec_host_cmd_status (*ec_host_cmd_handler_cb)(struct ec_host_cmd_handler_args *args)
```

## Enums

enum ec\_host\_cmd\_status

*Values:*

enumerator EC\_HOST\_CMD\_SUCCESS = 0

Host command was successful.

enumerator EC\_HOST\_CMD\_INVALID\_COMMAND = 1

The specified command id is not recognized or supported.

enumerator EC\_HOST\_CMD\_ERROR = 2

Generic Error.

enumerator EC\_HOST\_CMD\_INVALID\_PARAM = 3

One of more of the input request parameters is invalid.

enumerator EC\_HOST\_CMD\_ACCESS\_DENIED = 4

Host command is not permitted.

enumerator EC\_HOST\_CMD\_INVALID\_RESPONSE = 5

Response was invalid (e.g. not version 3 of header).

enumerator EC\_HOST\_CMD\_INVALID\_VERSION = 6

Host command id version unsupported.

enumerator EC\_HOST\_CMD\_INVALID\_CHECKSUM = 7

Checksum did not match

enumerator EC\_HOST\_CMD\_IN\_PROGRESS = 8

A host command is currently being processed.

enumerator EC\_HOST\_CMD\_UNAVAILABLE = 9

Requested information is currently unavailable.

enumerator EC\_HOST\_CMD\_TIMEOUT = 10

Timeout during processing.

enumerator EC\_HOST\_CMD\_OVERFLOW = 11

Data or table overflow.

enumerator EC\_HOST\_CMD\_INVALID\_HEADER = 12

Header is invalid or unsupported (e.g. not version 3 of header).

enumerator EC\_HOST\_CMD\_REQUEST\_TRUNCATED = 13

Did not receive all expected request data.

enumerator EC\_HOST\_CMD\_RESPONSE\_TOO\_BIG = 14

Response was too big to send within one response packet.

enumerator EC\_HOST\_CMD\_BUS\_ERROR = 15

Error on underlying communication bus.

enumerator EC\_HOST\_CMD\_BUSY = 16

System busy. Should retry later.

enumerator EC\_HOST\_CMD\_MAX = UINT16\_MAX

struct ec\_host\_cmd\_handler\_args

*#include <ec\_host\_cmd.h>* Arguments passed into every installed host command handler.

### Public Members

const void \*const input\_buf

The incoming data that can be cast to the handlers request type.

const uint16\_t input\_buf\_size

The number of valid bytes that can be read from *input\_buf*.

void \*const output\_buf

The data written to this buffer will be send to the host.

uint16\_t output\_buf\_size

[in/out] Upon entry, this is the maximum number of bytes that can be written to the *output\_buf*. Upon exit, this should be the number of bytes of *output\_buf* to send to the host.

const uint8\_t version

The version of the host command that is being requested. This will be a value that has been static registered as valid for the handler.

struct ec\_host\_cmd\_handler

*#include <ec\_host\_cmd.h>* Structure use for statically registering host command handlers.

### Public Members

*ec\_host\_cmd\_handler\_cb* handler

Callback routine to process commands that match *id*.

uint16\_t id

The numerical command id used as the lookup for commands.

uint16\_t version\_mask

The bitfield of all versions that the *handler* supports, where each bit value represents that the *handler* supports that version. E.g. *BIT(0)* correspond to version 0.

uint16\_t min\_rqt\_size

The minimum *input\_buf\_size* enforced by the framework before passing to the handler.

uint16\_t min\_rsp\_size

The minimum *output\_buf\_size* enforced by the framework before passing to the handler.

struct ec\_host\_cmd\_request\_header

*#include <ec\_host\_cmd.h>* Header for requests from host to embedded controller.

Represent the over-the-wire header in LE format for host command requests. This represent version 3 of the host command header. The requests are always sent from host to embedded controller.

### Public Members

uint8\_t prtcl\_ver

Should be 3. The EC will return EC\_HOST\_CMD\_INVALID\_HEADER if it receives a header with a version it doesn't know how to parse.

uint8\_t checksum

Checksum of response and data; sum of all bytes including checksum. Should total to 0.

uint16\_t cmd\_id

Id of command that is being sent.

uint8\_t cmd\_ver

Version of the specific *cmd\_id* being requested. Valid versions start at 0.

uint8\_t reserved

Unused byte in current protocol version; set to 0.

uint16\_t data\_len

Length of data which follows this header.

struct ec\_host\_cmd\_response\_header

*#include <ec\_host\_cmd.h>* Header for responses from embedded controller to host.

Represent the over-the-wire header in LE format for host command responses. This represent version 3 of the host command header. Responses are always sent from embedded controller to host.

### Public Members

uint8\_t prtcl\_ver

Should be 3.

uint8\_t checksum

Checksum of response and data; sum of all bytes including checksum. Should total to 0.

uint16\_t result

A *ec\_host\_cmd\_status* response code for specific command.

uint16\_t data\_len

Length of data which follows this header.

uint16\_t reserved

Unused bytes in current protocol version; set to 0.

### 7.21.7 EEPROM

#### Overview

The EEPROM API provides read and write access to Electrically Erasable Programmable Read-Only Memory (EEPROM) devices.

EEPROMs have an erase block size of 1 byte, a long lifetime, and allow overwriting data on byte-by-byte access.

#### Configuration Options

Related configuration options:

- **`:kconfig: `CONFIG_EEPROM``**

#### API Reference

*group* eeprom\_interface

EEPROM Interface.

#### Typedefs

```
typedef int (*eeprom_api_read)(const struct device *dev, off_t offset, void *data, size_t len)
```

```
typedef int (*eeprom_api_write)(const struct device *dev, off_t offset, const void *data, size_t len)
```

```
typedef size_t (*eeprom_api_size)(const struct device *dev)
```

#### Functions

```
int eeprom_read(const struct device *dev, off_t offset, void *data, size_t len)
```

Read data from EEPROM.

##### Parameters

- *dev* – EEPROM device
- *offset* – Address offset to read from.
- *data* – Buffer to store read data.

- `len` – Number of bytes to read.

**Returns** 0 on success, negative `errno` code on failure.

```
int eeprom_write(const struct device *dev, off_t offset, const void *data, size_t len)
```

Write data to EEPROM.

#### Parameters

- `dev` – EEPROM device
- `offset` – Address offset to write data to.
- `data` – Buffer with data to write.
- `len` – Number of bytes to write.

**Returns** 0 on success, negative `errno` code on failure.

```
size_t eeprom_get_size(const struct device *dev)
```

Get the size of the EEPROM in bytes.

#### Parameters

- `dev` – EEPROM device.

**Returns** EEPROM size in bytes.

```
struct eeprom_driver_api  
#include <eeprom.h>
```

## 7.21.8 Entropy

### Overview

The entropy API provides functions to retrieve entropy values from entropy hardware present on the platform. The entropy APIs are provided for use by the random subsystem and cryptographic services. They are not suitable to be used as random number generation functions.

### API Reference

```
group entropy_interface
```

Entropy Interface.

#### Defines

ENTROPY\_BUSYWAIT

#### Typedefs

```
typedef int (*entropy_get_entropy_t)(const struct device *dev, uint8_t *buffer, uint16_t length)
```

Callback API to get entropy.

See [\*entropy\\_get\\_entropy\(\)\*](#) for argument description

```
typedef int (*entropy_get_entropy_isr_t)(const struct device *dev, uint8_t *buffer, uint16_t length, uint32_t flags)
```

Callback API to get entropy from an ISR.

See [entropy\\_get\\_entropy\\_isr\(\)](#) for argument description

## Functions

```
int entropy_get_entropy(const struct device *dev, uint8_t *buffer, uint16_t length)
```

Fills a buffer with entropy. Blocks if required in order to generate the necessary random data.

### Parameters

- `dev` – Pointer to the entropy device.
- `buffer` – Buffer to fill with entropy.
- `length` – Buffer length.

### Return values

- 0 – on success.
- `-ERRNO` – `errno` code on error.

```
static inline int entropy_get_entropy_isr(const struct device *dev, uint8_t *buffer, uint16_t length, uint32_t flags)
```

Fills a buffer with entropy in a non-blocking or busy-wait manner. Callable from ISRs.

### Parameters

- `dev` – Pointer to the device structure.
- `buffer` – Buffer to fill with entropy.
- `length` – Buffer length.
- `flags` – Flags to modify the behavior of the call.

**Return values** `number` – of bytes filled with entropy or `-error`.

```
struct entropy_driver_api  
#include <entropy.h>
```

## 7.21.9 Flash

### Overview

#### Flash offset concept

Offsets used by the user API are expressed in relation to the flash memory beginning address. This rule shall be applied to all flash controller regular memory that layout is accessible via API for retrieving the layout of pages (see `option:CONFIG_FLASH_PAGE_LAYOUT`).

An exception from the rule may be applied to a vendor-specific flash dedicated-purpose region (such a region obviously can't be covered under API for retrieving the layout of pages).

### User API Reference

```
group flash_interface  
FLASH Interface.
```

## Typedefs

```
typedef bool (*flash_page_cb)(const struct flash\_pages\_info *info, void *data)
```

Callback type for iterating over flash pages present on a device.

The callback should return true to continue iterating, and false to halt.

### See also:

[flash\\_page\\_foreach\(\)](#)

**Param info** Information for current page

**Param data** Private data for callback

**Return** True to continue iteration, false to halt iteration.

## Functions

```
int flash_read(const struct device *dev, off_t offset, void *data, size_t len)
```

Read data from flash.

All flash drivers support reads without alignment restrictions on the read offset, the read size, or the destination address.

### Parameters

- `dev` – : flash dev
- `offset` – : Offset (byte aligned) to read
- `data` – : Buffer to store read data
- `len` – : Number of bytes to read.

**Returns** 0 on success, negative errno code on fail.

```
int flash_write(const struct device *dev, off_t offset, const void *data, size_t len)
```

Write buffer into flash memory.

All flash drivers support a source buffer located either in RAM or SoC flash, without alignment restrictions on the source address. Write size and offset must be multiples of the minimum write block size supported by the driver.

Any necessary write protection management is performed by the driver write implementation itself.

### Parameters

- `dev` – : flash device
- `offset` – : starting offset for the write
- `data` – : data to write
- `len` – : Number of bytes to write

**Returns** 0 on success, negative errno code on fail.

```
int flash_erase(const struct device *dev, off_t offset, size_t size)
```

Erase part or all of a flash memory.

Acceptable values of erase size and offset are subject to hardware-specific multiples of page size and offset. Please check the API implemented by the underlying sub driver, for example by using [flash\\_get\\_page\\_info\\_by\\_offs\(\)](#) if that is supported by your flash driver.

Any necessary erase protection management is performed by the driver erase implementation itself.

**See also:**

[\*flash\\_get\\_page\\_info\\_by\\_offs\(\)\*](#)

**See also:**

[\*flash\\_get\\_page\\_info\\_by\\_idx\(\)\*](#)

#### Parameters

- `dev` – : flash device
- `offset` – : erase area starting offset
- `size` – : size of area to be erased

**Returns** 0 on success, negative errno code on fail.

```
int flash_write_protection_set(const struct device *dev, bool enable)
```

Enable or disable write protection for a flash memory.

This API is deprecated and will be removed in Zephyr 2.8. It will be kept as No-Operation until removal. Flash write/erase protection management has been moved to write and erase operations implementations in flash driver shims. For Out-of-tree drivers which are not updated yet flash write/erase protection management is done in [\*flash\\_erase\(\)\*](#) and [\*flash\\_write\(\)\*](#) using deprecated

`write_protection`

shim handler.

#### Parameters

- `dev` – : flash device
- `enable` – : enable or disable flash write protection

**Returns** 0 on success, negative errno code on fail.

```
int flash_get_page_info_by_offs(const struct device *dev, off_t offset, struct flash\_pages\_info *info)
```

Get the size and start offset of flash page at certain flash offset.

#### Parameters

- `dev` – flash device
- `offset` – Offset within the page
- `info` – Page Info structure to be filled

**Returns** 0 on success, -EINVAL if page of the offset doesn't exist.

```
int flash_get_page_info_by_idx(const struct device *dev, uint32_t page_index, struct flash\_pages\_info *info)
```

Get the size and start offset of flash page of certain index.

#### Parameters

- `dev` – flash device
- `page_index` – Index of the page. Index are counted from 0.
- `info` – Page Info structure to be filled

**Returns** 0 on success, -EINVAL if page of the index doesn't exist.

```
size_t flash_get_page_count(const struct device *dev)
```

Get the total number of flash pages.

**Parameters**

- *dev* – flash device

**Returns** Number of flash pages.

```
void flash_page_foreach(const struct device *dev, flash_page_cb cb, void *data)
```

Iterate over all flash pages on a device.

This routine iterates over all flash pages on the given device, ordered by increasing start offset. For each page, it invokes the given callback, passing it the page's information and a private data object.

**Parameters**

- *dev* – Device whose pages to iterate over
- *cb* – Callback to invoke for each flash page
- *data* – Private data for callback function

```
int flash_sfdp_read(const struct device *dev, off_t offset, void *data, size_t len)
```

Read data from Serial Flash Discoverable Parameters.

This routine reads data from a serial flash device compatible with the JEDEC JESD216 standard for encoding flash memory characteristics.

Availability of this API is conditional on selecting CONFIG\_FLASH\_JESD216\_API and support of that functionality in the driver underlying *dev*.

**Parameters**

- *dev* – device from which parameters will be read
- *offset* – address within the SFDP region containing data of interest
- *data* – where the data to be read will be placed
- *len* – the number of bytes of data to be read

**Return values**

- 0 – on success
- -ENOTSUP – if the flash driver does not support SFDP access
- *negative* – values for other errors.

```
int flash_read_jedec_id(const struct device *dev, uint8_t *id)
```

Read the JEDEC ID from a compatible flash device.

**Parameters**

- *dev* – device from which id will be read
- *id* – pointer to a buffer of at least 3 bytes into which id will be stored

**Return values**

- 0 – on successful store of 3-byte JEDEC id
- -ENOTSUP – if flash driver doesn't support this function
- *negative* – values for other errors

```
size_t flash_get_write_block_size(const struct device *dev)
```

Get the minimum write block size supported by the driver.

The write block size supported by the driver might differ from the write block size of memory used because the driver might implements write-modify algorithm.

#### Parameters

- dev – flash device

**Returns** write block size in bytes.

```
const struct flash_parameters *flash_get_parameters(const struct device *dev)
```

Get pointer to *flash\_parameters* structure.

Returned pointer points to a structure that should be considered constant through a runtime, regardless if it is defined in RAM or Flash. Developer is free to cache the structure pointer or copy its contents.

**Returns** pointer to *flash\_parameters* structure characteristic for the device.

```
struct flash_parameters
```

*#include <flash.h>* Flash memory parameters. Contents of this structure suppose to be filled in during flash device initialization and stay constant through a runtime.

```
struct flash_pages_info
```

*#include <flash.h>*

## Implementation interface API Reference

```
group flash_internal_interface
```

FLASH internal Interface.

### Typedefs

```
typedef int (*flash_api_read)(const struct device *dev, off_t offset, void *data, size_t len)
```

```
typedef int (*flash_api_write)(const struct device *dev, off_t offset, const void *data, size_t len)
```

Flash write implementation handler type.

---

**Note:** Any necessary write protection management must be performed by the driver, with the driver responsible for ensuring the “write-protect” after the operation completes (successfully or not) matches the write-protect state when the operation was started.

---

```
typedef int (*flash_api_erase)(const struct device *dev, off_t offset, size_t size)
```

Flash erase implementation handler type.

---

**Note:** Any necessary erase protection management must be performed by the driver, with the driver responsible for ensuring the “erase-protect” after the operation completes (successfully or not) matches the erase-protect state when the operation was started.

---

```
typedef int (*flash_api_write_protection)(const struct device *dev, bool enable)
```

```
typedef const struct flash_parameters (*flash_api_get_parameters)(const struct device *dev)
```

```
typedef void (*flash_api_pages_layout)(const struct device *dev, const struct flash_pages_layout
**layout, size_t *layout_size)
```

Retrieve a flash device's layout.

A flash device layout is a run-length encoded description of the pages on the device. (Here, “page” means the smallest erasable area on the flash device.)

For flash memories which have uniform page sizes, this routine returns an array of length 1, which specifies the page size and number of pages in the memory.

Layouts for flash memories with nonuniform page sizes will be returned as an array with multiple elements, each of which describes a group of pages that all have the same size. In this case, the sequence of array elements specifies the order in which these groups occur on the device.

**Param dev** Flash device whose layout to retrieve.

**Param layout** The flash layout will be returned in this argument.

**Param layout\_size** The number of elements in the returned layout.

```
typedef int (*flash_api_sfdp_read)(const struct device *dev, off_t offset, void *data, size_t len)
```

```
typedef int (*flash_api_read_jedec_id)(const struct device *dev, uint8_t *id)
```

```
struct flash_pages_layout
#include <flash.h>
```

```
struct flash_driver_api
#include <flash.h>
```

## 7.21.10 GNA

### Overview

The GNA API provides access to Intel's Gaussian Mixture Model and Neural Network Accelerator (GNA).

### Configuration Options

Related configuration options:

- **`:kconfig: `CONFIG_INTEL_GNA``**

### API Reference

*group* gna\_interface

This file contains the driver APIs for Intel's Gaussian Mixture Model and Neural Network Accelerator (GNA)

## Enums

enum gna\_result

Result of an inference operation

*Values:*

enumerator GNA\_RESULT\_INFERENCE\_COMPLETE

enumerator GNA\_RESULT\_SATURATION\_OCCURRED

enumerator GNA\_RESULT\_OUTPUT\_BUFFER\_FULL\_ERROR

enumerator GNA\_RESULT\_PARAM\_OUT\_OF\_RANGE\_ERROR

enumerator GNA\_RESULT\_GENERIC\_ERROR

## Functions

static inline int gna\_configure(const struct *device* \*dev, struct *gna\_config* \*cfg)

Configure the GNA device.

Configure the GNA device. The GNA device must be configured before registering a model or performing inference

### Parameters

- dev – Pointer to the device structure for the driver instance.
- cfg – Device configuration information

### Return values

- 0 – If the configuration is successful
- A – negative error code in case of a failure.

static inline int gna\_register\_model(const struct *device* \*dev, struct *gna\_model\_info* \*model, void \*\*model\_handle)

Register a neural network model.

Register a neural network model with the GNA device A model needs to be registered before it can be used to perform inference

### Parameters

- dev – Pointer to the device structure for the driver instance.
- model – Information about the neural network model
- model\_handle – Handle to the registered model if registration succeeds

### Return values

- 0 – If registration of the model is successful.
- A – negative error code in case of a failure.

```
static inline int gna_deregister_model(const struct device *dev, void *model)
```

De-register a previously registered neural network model.

De-register a previously registered neural network model from the GNA device. De-registration may be done to free up memory for registering another model. Once de-registered, the model can no longer be used to perform inference.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `model` – Model handle output by `gna_register_model` API

#### Return values

- 0 – If de-registration of the model is successful.
- A – negative error code in case of a failure.

```
static inline int gna_infer(const struct device *dev, struct gna_inference_req *req, gna_callback  
                           callback)
```

Perform inference on a model with input vectors.

Make an inference request on a previously registered model with an input data vector. A callback is provided for notification of inference completion.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `req` – Information required to perform inference on a neural network
- `callback` – A callback function to notify inference completion

#### Return values

- 0 – If the request is accepted
- A – negative error code in case of a failure.

```
struct gna_config
```

*#include <gna.h>* GNA driver configuration structure. Currently empty.

```
struct gna_model_header
```

*#include <gna.h>* GNA Neural Network model header. Describes the key parameters of the neural network model.

```
struct gna_model_info
```

*#include <gna.h>* GNA Neural Network model information to be provided by application during model registration.

```
struct gna_inference_req
```

*#include <gna.h>* Request to perform inference on the given neural network model.

```
struct gna_inference_stats
```

*#include <gna.h>* Statistics of the inference operation returned after completion.

```
struct gna_inference_resp
```

*#include <gna.h>* Structure containing a response to the inference request.

## 7.21.11 GPIO

### Overview

### Configuration Options

Related configuration options:

- `:kconfig: `CONFIG_GPIO``

### API Reference

*group* gpio\_interface

GPIO Driver APIs.

#### GPIO input/output configuration flags

GPIO\_INPUT

Enables pin as input.

GPIO\_OUTPUT

Enables pin as output, no change to the output state.

GPIO\_DISCONNECTED

Disables pin for both input and output.

GPIO\_OUTPUT\_LOW

Configures GPIO pin as output and initializes it to a low state.

GPIO\_OUTPUT\_HIGH

Configures GPIO pin as output and initializes it to a high state.

GPIO\_OUTPUT\_INACTIVE

Configures GPIO pin as output and initializes it to a logic 0.

GPIO\_OUTPUT\_ACTIVE

Configures GPIO pin as output and initializes it to a logic 1.

#### GPIO interrupt configuration flags

The GPIO\_INT\_\* flags are used to specify how input GPIO pins will trigger interrupts. The interrupts can be sensitive to pin physical or logical level. Interrupts sensitive to pin logical level take into account GPIO\_ACTIVE\_LOW flag. If a pin was configured as Active Low, physical level low will be considered as logical level 1 (an active state), physical level high will be considered as logical level 0 (an inactive state).

GPIO\_INT\_DISABLE

Disables GPIO pin interrupt.

`GPIO_INT_EDGE_RISING`

Configures GPIO interrupt to be triggered on pin rising edge and enables it.

`GPIO_INT_EDGE_FALLING`

Configures GPIO interrupt to be triggered on pin falling edge and enables it.

`GPIO_INT_EDGE_BOTH`

Configures GPIO interrupt to be triggered on pin rising or falling edge and enables it.

`GPIO_INT_LEVEL_LOW`

Configures GPIO interrupt to be triggered on pin physical level low and enables it.

`GPIO_INT_LEVEL_HIGH`

Configures GPIO interrupt to be triggered on pin physical level high and enables it.

`GPIO_INT_EDGE_TO_INACTIVE`

Configures GPIO interrupt to be triggered on pin state change to logical level 0 and enables it.

`GPIO_INT_EDGE_TO_ACTIVE`

Configures GPIO interrupt to be triggered on pin state change to logical level 1 and enables it.

`GPIO_INT_LEVEL_INACTIVE`

Configures GPIO interrupt to be triggered on pin logical level 0 and enables it.

`GPIO_INT_LEVEL_ACTIVE`

Configures GPIO interrupt to be triggered on pin logical level 1 and enables it.

### GPIO drive strength flags

The `GPIO_DS_*` flags are used with `gpio_pin_configure` to specify the drive strength configuration of a GPIO pin.

The drive strength of individual pins can be configured independently for when the pin output is low and high.

The `GPIO_DS_*_LOW` enumerations define the drive strength of a pin when output is low.

The `GPIO_DS_*_HIGH` enumerations define the drive strength of a pin when output is high.

The interface supports two different drive strengths: `DFLT` - The lowest drive strength supported by the HW `ALT` - The highest drive strength supported by the HW

On hardware that supports only one standard drive strength, both `DFLT` and `ALT` have the same behavior.

`GPIO_DS_DFLT_LOW`

Default drive strength standard when GPIO pin output is low.

`GPIO_DS_ALT_LOW`

Alternative drive strength when GPIO pin output is low. For hardware that does not support configurable drive strength use the default drive strength.

GPIO\_DS\_DFLT\_HIGH

Default drive strength when GPIO pin output is high.

GPIO\_DS\_ALT\_HIGH

Alternative drive strength when GPIO pin output is high. For hardware that does not support configurable drive strengths use the default drive strength.

### GPIO pin active level flags

GPIO\_ACTIVE\_LOW

GPIO pin is active (has logical value '1') in low state.

GPIO\_ACTIVE\_HIGH

GPIO pin is active (has logical value '1') in high state.

### GPIO pin drive flags

GPIO\_OPEN\_DRAIN

Configures GPIO output in open drain mode (wired AND).

---

**Note:** 'Open Drain' mode also known as 'Open Collector' is an output configuration which behaves like a switch that is either connected to ground or disconnected.

---

GPIO\_OPEN\_SOURCE

Configures GPIO output in open source mode (wired OR).

---

**Note:** 'Open Source' is a term used by software engineers to describe output mode opposite to 'Open Drain'. It behaves like a switch that is either connected to power supply or disconnected. There exist no corresponding hardware schematic and the term is generally unknown to hardware engineers.

---

### GPIO pin bias flags

GPIO\_PULL\_UP

Enables GPIO pin pull-up.

GPIO\_PULL\_DOWN

Enable GPIO pin pull-down.

### GPIO pin voltage flags

The voltage flags are a Zephyr specific extension of the standard GPIO flags specified by the Linux GPIO binding. Only applicable if SoC allows to configure pin voltage per individual pin.

GPIO\_VOLTAGE\_DEFAULT

Set pin at the default voltage level

GPIO\_VOLTAGE\_1P8

Set pin voltage level at 1.8 V

GPIO\_VOLTAGE\_3P3

Set pin voltage level at 3.3 V

GPIO\_VOLTAGE\_5P0

Set pin voltage level at 5.0 V

## Defines

GPIO\_INT\_DEBOUNCE

Enable GPIO pin debounce.

---

**Note:** Drivers that do not support a debounce feature should ignore this flag rather than rejecting the configuration with -ENOTSUP.

---

GPIO\_DT\_SPEC\_GET\_BY\_IDX(node\_id, prop, idx)

Static initializer for a [gpio\\_dt\\_spec](#).

This returns a static initializer for a [gpio\\_dt\\_spec](#) structure given a devicetree node identifier, a property specifying a GPIO and an index.

Example devicetree fragment:

```
n: node {
    foo-gpios = <&gpio0 1 GPIO_ACTIVE_LOW>,
               <&gpio1 2 GPIO_ACTIVE_LOW>;
}
```

Example usage:

```
const struct gpio_dt_spec spec = GPIO_DT_SPEC_GET_BY_IDX(DT_NODELABEL(n),
                                                         foo_gpios, 1);

// Initializes 'spec' to:
// {
//     .port = DEVICE_DT_GET(DT_NODELABEL(gpio1)),
//     .pin = 2,
//     .dt_flags = GPIO_ACTIVE_LOW
// }
```

The ‘gpio’ field must still be checked for readiness, e.g. using [device\\_is\\_ready\(\)](#). It is an error to use this macro unless the node exists, has the given property, and that property specifies a GPIO controller, pin number, and flags as shown above.

### Parameters

- `node_id` – devicetree node identifier
- `prop` – lowercase-and-underscores property name
- `idx` – logical index into “prop”

**Returns** static initializer for a struct *gpio\_dt\_spec* for the property

`GPIO_DT_SPEC_GET_BY_IDX_OR(node_id, prop, idx, default_value)`

Like *GPIO\_DT\_SPEC\_GET\_BY\_IDX()*, with a fallback to a default value.

If the devicetree node identifier ‘node\_id’ refers to a node with a property ‘prop’, this expands to *GPIO\_DT\_SPEC\_GET\_BY\_IDX(node\_id, prop, idx)*. The `default_value` parameter is not expanded in this case.

Otherwise, this expands to `default_value`.

**Parameters**

- `node_id` – devicetree node identifier
- `prop` – lowercase-and-underscores property name
- `idx` – logical index into “prop”
- `default_value` – fallback value to expand to

**Returns** static initializer for a struct *gpio\_dt\_spec* for the property, or `default_value` if the node or property do not exist

`GPIO_DT_SPEC_GET(node_id, prop)`

Equivalent to *GPIO\_DT\_SPEC\_GET\_BY\_IDX(node\_id, prop, 0)*.

**See also:**

*GPIO\_DT\_SPEC\_GET\_BY\_IDX()*

**Parameters**

- `node_id` – devicetree node identifier
- `prop` – lowercase-and-underscores property name

**Returns** static initializer for a struct *gpio\_dt\_spec* for the property

`GPIO_DT_SPEC_GET_OR(node_id, prop, default_value)`

Equivalent to *GPIO\_DT\_SPEC\_GET\_BY\_IDX\_OR(node\_id, prop, 0, default\_value)*.

**See also:**

*GPIO\_DT\_SPEC\_GET\_BY\_IDX\_OR()*

**Parameters**

- `node_id` – devicetree node identifier
- `prop` – lowercase-and-underscores property name
- `default_value` – fallback value to expand to

**Returns** static initializer for a struct *gpio\_dt\_spec* for the property

`GPIO_DT_SPEC_INST_GET_BY_IDX(inst, prop, idx)`

Static initializer for a *gpio\_dt\_spec* from a `DT_DRV_COMPAT` instance’s GPIO property at an index.

**See also:**

*GPIO\_DT\_SPEC\_GET\_BY\_IDX()*

**Parameters**

- `inst` – DT\_DRV\_COMPAT instance number
- `prop` – lowercase-and-underscores property name
- `idx` – logical index into “prop”

**Returns** static initializer for a struct *gpio\_dt\_spec* for the property

`GPIO_DT_SPEC_INST_GET_BY_IDX_OR(inst, prop, idx, default_value)`

Static initializer for a *gpio\_dt\_spec* from a DT\_DRV\_COMPAT instance’s GPIO property at an index, with fallback.

**See also:**

[\*GPIO\\_DT\\_SPEC\\_GET\\_BY\\_IDX\(\)\*](#)

**Parameters**

- `inst` – DT\_DRV\_COMPAT instance number
- `prop` – lowercase-and-underscores property name
- `idx` – logical index into “prop”
- `default_value` – fallback value to expand to

**Returns** static initializer for a struct *gpio\_dt\_spec* for the property

`GPIO_DT_SPEC_INST_GET(inst, prop)`

Equivalent to [\*GPIO\\_DT\\_SPEC\\_INST\\_GET\\_BY\\_IDX\(inst, prop, 0\)\*](#).

**See also:**

[\*GPIO\\_DT\\_SPEC\\_INST\\_GET\\_BY\\_IDX\(\)\*](#)

**Parameters**

- `inst` – DT\_DRV\_COMPAT instance number
- `prop` – lowercase-and-underscores property name

**Returns** static initializer for a struct *gpio\_dt\_spec* for the property

`GPIO_DT_SPEC_INST_GET_OR(inst, prop, default_value)`

Equivalent to [\*GPIO\\_DT\\_SPEC\\_INST\\_GET\\_BY\\_IDX\\_OR\(inst, prop, 0, default\\_value\)\*](#).

**See also:**

[\*GPIO\\_DT\\_SPEC\\_INST\\_GET\\_BY\\_IDX\(\)\*](#)

**Parameters**

- `inst` – DT\_DRV\_COMPAT instance number
- `prop` – lowercase-and-underscores property name
- `default_value` – fallback value to expand to

**Returns** static initializer for a struct *gpio\_dt\_spec* for the property

GPIO\_MAX\_PINS\_PER\_PORT

Maximum number of pins that are supported by `gpio_port_pins_t`.

## Typedefs

`typedef uint32_t gpio_port_pins_t`

Identifies a set of pins associated with a port.

The pin with index `n` is present in the set if and only if the bit identified by  $(1U \ll n)$  is set.

`typedef uint32_t gpio_port_value_t`

Provides values for a set of pins associated with a port.

The value for a pin with index `n` is high (physical mode) or active (logical mode) if and only if the bit identified by  $(1U \ll n)$  is set. Otherwise the value for the pin is low (physical mode) or inactive (logical mode).

Values of this type are often paired with a `gpio_port_pins_t` value that specifies which encoded pin values are valid for the operation.

`typedef uint8_t gpio_pin_t`

Provides a type to hold a GPIO pin index.

This reduced-size type is sufficient to record a pin number, e.g. from a devicetree GPIOs property.

`typedef uint8_t gpio_dt_flags_t`

Provides a type to hold GPIO devicetree flags.

All GPIO flags that can be expressed in devicetree fit in the low 8 bits of the full flags field, so use a reduced-size type to record that part of a GPIOs property.

`typedef uint32_t gpio_flags_t`

Provides a type to hold GPIO configuration flags.

This type is sufficient to hold all flags used to control GPIO configuration, whether pin or interrupt.

`typedef void (*gpio_callback_handler_t)(const struct device *port, struct gpio\_callback *cb, gpio\_port\_pins\_t pins)`

Define the application callback handler function signature.

Note: `cb` pointer can be used to retrieve private data through [CONTAINER\\_OF\(\)](#) if original struct [gpio\\_callback](#) is stored in another private structure.

**Param port** Device struct for the GPIO device.

**Param cb** Original struct [gpio\\_callback](#) owning this handler

**Param pins** Mask of pins that triggers the callback handler

## Functions

```
int gpio_pin_interrupt_configure(const struct device *port, gpio_pin_t pin, gpio_flags_t flags)
```

Configure pin interrupt.

---

**Note:** This function can also be used to configure interrupts on pins not controlled directly by the GPIO module. That is, pins which are routed to other modules such as I2C, SPI, UART.

---

#### Parameters

- `port` – Pointer to device structure for the driver instance.
- `pin` – Pin number.
- `flags` – Interrupt configuration flags as defined by `GPIO_INT_*`.

#### Return values

- 0 – If successful.
- `-ENOTSUP` – If any of the configuration options is not supported (unless otherwise directed by flag documentation).
- `-EINVAL` – Invalid argument.
- `-EBUSY` – Interrupt line required to configure pin interrupt is already in use.
- `-EIO` – I/O error when accessing an external GPIO chip.
- `-EWOULDBLOCK` – if operation would block.

```
static inline int gpio_pin_interrupt_configure_dt(const struct gpio_dt_spec *spec, gpio_flags_t flags)
```

Configure pin interrupts from a *gpio\_dt\_spec*.

This is equivalent to:

```
gpio_pin_interrupt_configure(spec->port, spec->pin, flags);
```

The `spec->dt_flags` value is not used.

#### Parameters

- `spec` – GPIO specification from devicetree
- `flags` – interrupt configuration flags

**Returns** a value from *gpio\_pin\_interrupt\_configure()*

```
int gpio_pin_configure(const struct device *port, gpio_pin_t pin, gpio_flags_t flags)
```

Configure a single pin.

#### Parameters

- `port` – Pointer to device structure for the driver instance.
- `pin` – Pin number to configure.
- `flags` – Flags for pin configuration: ‘GPIO input/output configuration flags’, ‘GPIO drive strength flags’, ‘GPIO pin drive flags’, ‘GPIO pin bias flags’, `GPIO_INT_DEBOUNCE`.

#### Return values

- 0 – If successful.
- `-ENOTSUP` – if any of the configuration options is not supported (unless otherwise directed by flag documentation).
- `-EINVAL` – Invalid argument.

- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

static inline int gpio\_pin\_configure\_dt(const struct [gpio\\_dt\\_spec](#) \*spec, [gpio\\_flags\\_t](#) extra\_flags)

Configure a single pin from a [gpio\\_dt\\_spec](#) and some extra flags.

This is equivalent to:

```
gpio_pin_configure(spec->port, spec->pin, spec->dt_flags | extra_flags);
```

#### Parameters

- spec – GPIO specification from devicetree
- extra\_flags – additional flags

**Returns** a value from [gpio\\_pin\\_configure\(\)](#)

int gpio\_port\_get\_raw(const struct [device](#) \*port, [gpio\\_port\\_value\\_t](#) \*value)

Get physical level of all input pins in a port.

A low physical level on the pin will be interpreted as value 0. A high physical level will be interpreted as value 1. This function ignores GPIO\_ACTIVE\_LOW flag.

Value of a pin with index n will be represented by bit n in the returned port value.

#### Parameters

- port – Pointer to the device structure for the driver instance.
- value – Pointer to a variable where pin values will be stored.

#### Return values

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

static inline int gpio\_port\_get(const struct [device](#) \*port, [gpio\\_port\\_value\\_t](#) \*value)

Get logical level of all input pins in a port.

Get logical level of an input pin taking into account GPIO\_ACTIVE\_LOW flag. If pin is configured as Active High, a low physical level will be interpreted as logical value 0. If pin is configured as Active Low, a low physical level will be interpreted as logical value 1.

Value of a pin with index n will be represented by bit n in the returned port value.

#### Parameters

- port – Pointer to the device structure for the driver instance.
- value – Pointer to a variable where pin values will be stored.

#### Return values

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

int gpio\_port\_set\_masked\_raw(const struct [device](#) \*port, [gpio\\_port\\_pins\\_t](#) mask, [gpio\\_port\\_value\\_t](#) value)

Set physical level of output pins in a port.

Writing value 0 to the pin will set it to a low physical level. Writing value 1 will set it to a high physical level. This function ignores GPIO\_ACTIVE\_LOW flag.

Pin with index *n* is represented by bit *n* in mask and value parameter.

**Parameters**

- *port* – Pointer to the device structure for the driver instance.
- *mask* – Mask indicating which pins will be modified.
- *value* – Value assigned to the output pins.

**Return values**

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

```
static inline int gpio_port_set_masked(const struct device *port, gpio_port_pins_t mask,  
                                     gpio_port_value_t value)
```

Set logical level of output pins in a port.

Set logical level of an output pin taking into account GPIO\_ACTIVE\_LOW flag. Value 0 sets the pin in logical 0 / inactive state. Value 1 sets the pin in logical 1 / active state. If pin is configured as Active High, the default, setting it in inactive state will force the pin to a low physical level. If pin is configured as Active Low, setting it in inactive state will force the pin to a high physical level.

Pin with index *n* is represented by bit *n* in mask and value parameter.

**Parameters**

- *port* – Pointer to the device structure for the driver instance.
- *mask* – Mask indicating which pins will be modified.
- *value* – Value assigned to the output pins.

**Return values**

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

```
int gpio_port_set_bits_raw(const struct device *port, gpio_port_pins_t pins)
```

Set physical level of selected output pins to high.

**Parameters**

- *port* – Pointer to the device structure for the driver instance.
- *pins* – Value indicating which pins will be modified.

**Return values**

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

```
static inline int gpio_port_set_bits(const struct device *port, gpio_port_pins_t pins)
```

Set logical level of selected output pins to active.

**Parameters**

- *port* – Pointer to the device structure for the driver instance.
- *pins* – Value indicating which pins will be modified.

**Return values**

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

int gpio\_port\_clear\_bits\_raw(const struct *device* \*port, *gpio\_port\_pins\_t* pins)

Set physical level of selected output pins to low.

#### Parameters

- port – Pointer to the device structure for the driver instance.
- pins – Value indicating which pins will be modified.

#### Return values

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

static inline int gpio\_port\_clear\_bits(const struct *device* \*port, *gpio\_port\_pins\_t* pins)

Set logical level of selected output pins to inactive.

#### Parameters

- port – Pointer to the device structure for the driver instance.
- pins – Value indicating which pins will be modified.

#### Return values

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

int gpio\_port\_toggle\_bits(const struct *device* \*port, *gpio\_port\_pins\_t* pins)

Toggle level of selected output pins.

#### Parameters

- port – Pointer to the device structure for the driver instance.
- pins – Value indicating which pins will be modified.

#### Return values

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

static inline int gpio\_port\_set\_clr\_bits\_raw(const struct *device* \*port, *gpio\_port\_pins\_t* set\_pins, *gpio\_port\_pins\_t* clear\_pins)

Set physical level of selected output pins.

#### Parameters

- port – Pointer to the device structure for the driver instance.
- set\_pins – Value indicating which pins will be set to high.
- clear\_pins – Value indicating which pins will be set to low.

#### Return values

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.

- `-EWOULDBLOCK` – if operation would block.

```
static inline int gpio_port_set_clr_bits(const struct device *port, gpio_port_pins_t set_pins,  
                                         gpio_port_pins_t clear_pins)
```

Set logical level of selected output pins.

#### Parameters

- `port` – Pointer to the device structure for the driver instance.
- `set_pins` – Value indicating which pins will be set to active.
- `clear_pins` – Value indicating which pins will be set to inactive.

#### Return values

- 0 – If successful.
- `-EIO` – I/O error when accessing an external GPIO chip.
- `-EWOULDBLOCK` – if operation would block.

```
static inline int gpio_pin_get_raw(const struct device *port, gpio_pin_t pin)
```

Get physical level of an input pin.

A low physical level on the pin will be interpreted as value 0. A high physical level will be interpreted as value 1. This function ignores `GPIO_ACTIVE_LOW` flag.

#### Parameters

- `port` – Pointer to the device structure for the driver instance.
- `pin` – Pin number.

#### Return values

- 1 – If pin physical level is high.
- 0 – If pin physical level is low.
- `-EIO` – I/O error when accessing an external GPIO chip.
- `-EWOULDBLOCK` – if operation would block.

```
static inline int gpio_pin_get(const struct device *port, gpio_pin_t pin)
```

Get logical level of an input pin.

Get logical level of an input pin taking into account `GPIO_ACTIVE_LOW` flag. If pin is configured as Active High, a low physical level will be interpreted as logical value 0. If pin is configured as Active Low, a low physical level will be interpreted as logical value 1.

Note: If pin is configured as Active High, the default, `gpio_pin_get()` function is equivalent to `gpio_pin_get_raw()`.

#### Parameters

- `port` – Pointer to the device structure for the driver instance.
- `pin` – Pin number.

#### Return values

- 1 – If pin logical value is 1 / active.
- 0 – If pin logical value is 0 / inactive.
- `-EIO` – I/O error when accessing an external GPIO chip.
- `-EWOULDBLOCK` – if operation would block.

```
static inline int gpio_pin_get_dt(const struct gpio_dt_spec *spec)
```

Get logical level of an input pin from a *gpio\_dt\_spec*.

This is equivalent to:

```
gpio_pin_get(spec->port, spec->pin);
```

#### Parameters

- *spec* – GPIO specification from devicetree

**Returns** a value from *gpio\_pin\_get()*

```
static inline int gpio_pin_set_raw(const struct device *port, gpio_pin_t pin, int value)
```

Set physical level of an output pin.

Writing value 0 to the pin will set it to a low physical level. Writing any value other than 0 will set it to a high physical level. This function ignores GPIO\_ACTIVE\_LOW flag.

#### Parameters

- *port* – Pointer to the device structure for the driver instance.
- *pin* – Pin number.
- *value* – Value assigned to the pin.

#### Return values

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

```
static inline int gpio_pin_set(const struct device *port, gpio_pin_t pin, int value)
```

Set logical level of an output pin.

Set logical level of an output pin taking into account GPIO\_ACTIVE\_LOW flag. Value 0 sets the pin in logical 0 / inactive state. Any value other than 0 sets the pin in logical 1 / active state. If pin is configured as Active High, the default, setting it in inactive state will force the pin to a low physical level. If pin is configured as Active Low, setting it in inactive state will force the pin to a high physical level.

Note: If pin is configured as Active High, *gpio\_pin\_set()* function is equivalent to *gpio\_pin\_set\_raw()*.

#### Parameters

- *port* – Pointer to the device structure for the driver instance.
- *pin* – Pin number.
- *value* – Value assigned to the pin.

#### Return values

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

```
static inline int gpio_pin_set_dt(const struct gpio_dt_spec *spec, int value)
```

Set logical level of a output pin from a *gpio\_dt\_spec*.

This is equivalent to:

```
gpio_pin_set(spec->port, spec->pin, value);
```

**Parameters**

- `spec` – GPIO specification from devicetree
- `value` – Value assigned to the pin.

**Returns** a value from `gpio_pin_set()`

static inline int `gpio_pin_toggle`(const struct `device` \*port, `gpio_pin_t` pin)  
Toggle pin level.

**Parameters**

- `port` – Pointer to the device structure for the driver instance.
- `pin` – Pin number.

**Return values**

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

static inline int `gpio_pin_toggle_dt`(const struct `gpio_dt_spec` \*spec)  
Toggle pin level from a `gpio_dt_spec`.

This is equivalent to:

```
gpio_pin_toggle(spec->port, spec->pin);
```

**Parameters**

- `spec` – GPIO specification from devicetree

**Returns** a value from `gpio_pin_toggle()`

static inline void `gpio_init_callback`(struct `gpio_callback` \*callback, `gpio_callback_handler_t` handler, `gpio_port_pins_t` pin\_mask)

Helper to initialize a struct `gpio_callback` properly.

**Parameters**

- `callback` – A valid Application's callback structure pointer.
- `handler` – A valid handler function pointer.
- `pin_mask` – A bit mask of relevant pins for the handler

static inline int `gpio_add_callback`(const struct `device` \*port, struct `gpio_callback` \*callback)  
Add an application callback.

Note: enables to add as many callback as needed on the same port.

---

**Note:** Callbacks may be added to the device from within a callback handler invocation, but whether they are invoked for the current GPIO event is not specified.

---

**Parameters**

- `port` – Pointer to the device structure for the driver instance.
- `callback` – A valid Application's callback structure pointer.

**Returns** 0 if successful, negative errno code on failure.

```
static inline int gpio_remove_callback(const struct device *port, struct gpio_callback *callback)
```

Remove an application callback.

Note: enables to remove as many callbacks as added through *gpio\_add\_callback()*.

**Warning:** It is explicitly permitted, within a callback handler, to remove the registration for the callback that is running, i.e. *callback*. Attempts to remove other registrations on the same device may result in undefined behavior, including failure to invoke callbacks that remain registered and unintended invocation of removed callbacks.

#### Parameters

- *port* – Pointer to the device structure for the driver instance.
- *callback* – A valid application's callback structure pointer.

**Returns** 0 if successful, negative *errno* code on failure.

```
int gpio_get_pending_int(const struct device *dev)
```

Function to get pending interrupts.

The purpose of this function is to return the interrupt status register for the device. This is especially useful when waking up from low power states to check the wake up source.

#### Parameters

- *dev* – Pointer to the device structure for the driver instance.

#### Return values

- *status* – != 0 if at least one gpio interrupt is pending.
- 0 – if no gpio interrupt is pending.

```
struct gpio_dt_spec
```

*#include <gpio.h>* Provides a type to hold GPIO information specified in devicetree.

This type is sufficient to hold a GPIO device pointer, pin number, and the subset of the flags used to control GPIO configuration which may be given in devicetree.

```
struct gpio_driver_config
```

*#include <gpio.h>* This structure is common to all GPIO drivers and is expected to be the first element in the object pointed to by the *config* field in the device structure.

```
struct gpio_driver_data
```

*#include <gpio.h>* This structure is common to all GPIO drivers and is expected to be the first element in the driver's struct *driver\_data* declaration.

```
struct gpio_callback
```

*#include <gpio.h>* GPIO callback structure.

Used to register a callback in the driver instance callback list. As many callbacks as needed can be added as long as each of them are unique pointers of struct *gpio\_callback*. Beware such structure should not be allocated on stack.

Note: To help setting it, see *gpio\_init\_callback()* below

## Public Members

`sys_snode_t node`

This is meant to be used in the driver and the user should not mess with it (see `drivers/gpio/gpio_utils.h`)

`gpio_callback_handler_t handler`

Actual callback function being called when relevant.

`gpio_port_pins_t pin_mask`

A mask of pins the callback is interested in, if 0 the callback will never be called. Such `pin_mask` can be modified whenever necessary by the owner, and thus will affect the handler being called or not. The selected pins must be configured to trigger an interrupt.

## 7.21.12 Hardware Information

### Overview

The HW Info API provides access to hardware information such as device identifiers and reset cause flags.

Reset cause flags can be used to determine why the device was reset; for example due to a watchdog timeout or due to power cycling. Different devices support different subset of flags. Use `hwinfo_get_supported_reset_cause` to retrieve the flags that are supported by that device.

### Configuration Options

Related configuration options:

- `:kconfig: `CONFIG_HWINFO``

### API Reference

`group hwinfo_interface`

Hardware Information Interface.

#### Defines

`RESET_PIN`

`RESET_SOFTWARE`

`RESET_BROWNOUT`

`RESET_POR`

`RESET_WATCHDOG`

RESET\_DEBUG

RESET\_SECURITY

RESET\_LOW\_POWER\_WAKE

RESET\_CPU\_LOCKUP

RESET\_PARITY

RESET\_PLL

RESET\_CLOCK

## Functions

`ssize_t hwinfo_get_device_id(uint8_t *buffer, size_t length)`

Copy the device id to a buffer.

This routine copies “length” number of bytes of the device ID to the buffer. If the device ID is smaller than length, the rest of the buffer is left unchanged. The ID depends on the hardware and is not guaranteed unique.

Drivers are responsible for ensuring that the ID data structure is a sequence of bytes. The returned ID value is not supposed to be interpreted based on vendor-specific assumptions of byte order. It should express the identifier as a raw byte sequence, doing any endian conversion necessary so that a hex representation of the bytes produces the intended serial number.

### Parameters

- `buffer` – Buffer to write the ID to.
- `length` – Max length of the buffer.

### Return values

- `size` – of the device ID copied.
- `-ENOTSUP` – if there is no implementation for the particular device.
- any – negative value on driver specific errors.

`int hwinfo_get_reset_cause(uint32_t *cause)`

Retrieve cause of device reset.

This routine retrieves the flags that indicate why the device was reset.

On some platforms the reset cause flags accumulate between successive resets and this routine may return multiple flags indicating all reset causes since the device was powered on. If you need to retrieve the cause only for the most recent reset call `hwinfo_clear_reset_cause` after calling this routine to clear the hardware flags before the next reset event.

Successive calls to this routine will return the same value, unless `hwinfo_clear_reset_cause` has been called.

### Parameters

- `cause` – OR'd `reset_cause` flags

**Return values**

- zero – if successful.
- -ENOTSUP – if there is no implementation for the particular device.
- any – negative value on driver specific errors.

int hwinfo\_clear\_reset\_cause(void)

Clear cause of device reset.

Clears reset cause flags.

**Return values**

- zero – if successful.
- -ENOTSUP – if there is no implementation for the particular device.
- any – negative value on driver specific errors.

int hwinfo\_get\_supported\_reset\_cause(uint32\_t \*supported)

Get supported reset cause flags.

Retrieves all reset\_cause flags that are supported by this device.

**Parameters**

- supported – OR'd reset\_cause flags that are supported

**Return values**

- zero – if successful.
- -ENOTSUP – if there is no implementation for the particular device.
- any – negative value on driver specific errors.

## 7.21.13 I2C EEPROM Slave

### Overview

### API Reference

group i2c\_eeprom\_slave\_api

I2C EEPROM Slave Driver API.

### Functions

int eeprom\_slave\_program(const struct [device](#) \*dev, const uint8\_t \*eeprom\_data, unsigned int length)

Program memory of the virtual EEPROM.

**Parameters**

- dev – Pointer to the device structure for the driver instance.
- eeprom\_data – Pointer of data to program into the virtual eeprom memory
- length – Length of data to program into the virtual eeprom memory

**Return values**

- 0 – If successful.

- -EINVAL – Invalid data size

int eeprom\_slave\_read(const struct [device](#) \*dev, uint8\_t \*eeprom\_data, unsigned int offset)

Read single byte of virtual EEPROM memory.

#### Parameters

- dev – Pointer to the device structure for the driver instance.
- eeprom\_data – Pointer of byte where to store the virtual eeprom memory
- offset – Offset into EEPROM memory where to read the byte

#### Return values

- 0 – If successful.
- -EINVAL – Invalid data pointer or offset

## 7.21.14 I2C

### Overview

---

**Note:** Zephyr recognizes the need to change the terms “master” and “slave” used in the current [I2C Specification](#). This will be done when the conditions identified in [Rule A.2: Inclusive Language](#) have been met. Existing documentation, data structures, functions, and value symbols in code are likely to change at that point.

---

**I2C** (Inter-Integrated Circuit, pronounced “eye squared see”) is a commonly-used two-signal shared peripheral interface bus. Many system-on-chip solutions provide controllers that communicate on an I2C bus. Devices on the bus can operate in two roles: as a “master” that initiates transactions and controls the clock, or as a “slave” that responds to transaction commands. A I2C controller on a given SoC will generally support the master role, and some will also support the slave mode. Zephyr has API for both roles.

**I2C Master API** Zephyr’s I2C master API is used when an I2C peripheral controls the bus, in particularly the start and stop conditions and the clock. This is the most common mode, used to interact with I2C devices like sensors and serial memory.

This API is supported in all in-tree I2C peripheral drivers and is considered stable.

**I2C Slave API** Zephyr’s I2C slave API is used when an I2C peripheral responds to transactions initiated by a different controller on the bus. It might be used for a Zephyr application with transducer roles that are controlled by another device such as a host processor.

This API is supported in very few in-tree I2C peripheral drivers. The API is considered experimental, as it is not compatible with the capabilities of all I2C peripherals supported in master mode.

### Configuration Options

Related configuration options:

- `:kconfig: `CONFIG_I2C``

## API Reference

group i2c\_interface

I2C Interface.

### Defines

I2C\_SPEED\_STANDARD

I2C Standard Speed: 100 kHz

I2C\_SPEED\_FAST

I2C Fast Speed: 400 kHz

I2C\_SPEED\_FAST\_PLUS

I2C Fast Plus Speed: 1 MHz

I2C\_SPEED\_HIGH

I2C High Speed: 3.4 MHz

I2C\_SPEED\_ULTRA

I2C Ultra Fast Speed: 5 MHz

I2C\_SPEED\_SHIFT

I2C\_SPEED\_SET(speed)

I2C\_SPEED\_MASK

I2C\_SPEED\_GET(cfg)

I2C\_ADDR\_10\_BITS

Use 10-bit addressing. DEPRECATED - Use I2C\_MSG\_ADDR\_10\_BITS instead.

I2C\_MODE\_MASTER

Controller to act as Master.

I2C\_DT\_SPEC\_GET(node\_id)

Structure initializer for *i2c\_dt\_spec* from devicetree.

This helper macro expands to a static initializer for a struct *i2c\_dt\_spec* by reading the relevant bus and address data from the devicetree.

#### Parameters

- *node\_id* – Devicetree node identifier for the I2C device whose struct *i2c\_dt\_spec* to create an initializer for

I2C\_DT\_SPEC\_INST\_GET(inst)

Structure initializer for *i2c\_dt\_spec* from devicetree instance.

This is equivalent to *I2C\_DT\_SPEC\_GET(DT\_DRV\_INST(inst))*.

#### Parameters

- *inst* – Devicetree instance number

`I2C_MSG_WRITE`

Write message to I2C bus.

`I2C_MSG_READ`

Read message from I2C bus.

`I2C_MSG_STOP`

Send STOP after this message.

`I2C_MSG_RESTART`

RESTART I2C transaction for this message.

---

**Note:** Not all I2C drivers have or require explicit support for this feature. Some drivers require this be present on a read message that follows a write, or vice-versa. Some drivers will merge adjacent fragments into a single transaction using this flag; some will not.

---

`I2C_MSG_ADDR_10_BITS`

Use 10-bit addressing for this message.

---

**Note:** Not all SoC I2C implementations support this feature.

---

`I2C_SLAVE_FLAGS_ADDR_10_BITS`

Slave device responds to 10-bit addressing.

`I2C_DECLARE_CLIENT_CONFIG`

`I2C_CLIENT(_master, _addr)`

`I2C_GET_MASTER(_conf)`

`I2C_GET_ADDR(_conf)`

## Typedefs

```
typedef int (*i2c_slave_write_requested_cb_t)(struct i2c_slave_config *config)
```

Function called when a write to the device is initiated.

This function is invoked by the controller when the bus completes a start condition for a write operation to the address associated with a particular device.

A success return shall cause the controller to ACK the next byte received. An error return shall cause the controller to NACK the next byte received.

**Param config** the configuration structure associated with the device to which the operation is addressed.

**Return** 0 if the write is accepted, or a negative error code.

```
typedef int (*i2c_slave_write_received_cb_t)(struct i2c_slave_config *config, uint8_t val)
```

Function called when a write to the device is continued.

This function is invoked by the controller when it completes reception of a byte of data in an ongoing write operation to the device.

A success return shall cause the controller to ACK the next byte received. An error return shall cause the controller to NACK the next byte received.

**Param config** the configuration structure associated with the device to which the operation is addressed.

**Param val** the byte received by the controller.

**Return** 0 if more data can be accepted, or a negative error code.

```
typedef int (*i2c_slave_read_requested_cb_t)(struct i2c_slave_config *config, uint8_t *val)
```

Function called when a read from the device is initiated.

This function is invoked by the controller when the bus completes a start condition for a read operation from the address associated with a particular device.

The value returned in \*val will be transmitted. A success return shall cause the controller to react to additional read operations. An error return shall cause the controller to ignore bus operations until a new start condition is received.

**Param config** the configuration structure associated with the device to which the operation is addressed.

**Param val** pointer to storage for the first byte of data to return for the read request.

**Return** 0 if more data can be requested, or a negative error code.

```
typedef int (*i2c_slave_read_processed_cb_t)(struct i2c_slave_config *config, uint8_t *val)
```

Function called when a read from the device is continued.

This function is invoked by the controller when the bus is ready to provide additional data for a read operation from the address associated with the device device.

The value returned in \*val will be transmitted. A success return shall cause the controller to react to additional read operations. An error return shall cause the controller to ignore bus operations until a new start condition is received.

**Param config** the configuration structure associated with the device to which the operation is addressed.

**Param val** pointer to storage for the next byte of data to return for the read request.

**Return** 0 if data has been provided, or a negative error code.

```
typedef int (*i2c_slave_stop_cb_t)(struct i2c_slave_config *config)
```

Function called when a stop condition is observed after a start condition addressed to a particular device.

This function is invoked by the controller when the bus is ready to provide additional data for a read operation from the address associated with the device device. After the function returns the controller shall enter a state where it is ready to react to new start conditions.

**Param config** the configuration structure associated with the device to which the operation is addressed.

**Return** Ignored.

## Functions

int i2c\_configure(const struct *device* \*dev, uint32\_t dev\_config)

Configure operation of a host controller.

### Parameters

- dev – Pointer to the device structure for the driver instance.
- dev\_config – Bit-packed 32-bit value to the device runtime configuration for the I2C controller.

### Return values

- 0 – If successful.
- -EIO – General input / output error, failed to configure device.

int i2c\_transfer(const struct *device* \*dev, struct *i2c\_msg* \*msgs, uint8\_t num\_msgs, uint16\_t addr)

Perform data transfer to another I2C device in master mode.

This routine provides a generic interface to perform data transfer to another I2C device synchronously. Use *i2c\_read()*/*i2c\_write()* for simple read or write.

The array of message *msgs* must not be NULL. The number of message *num\_msgs* may be zero, in which case no transfer occurs.

---

**Note:** Not all scatter/gather transactions can be supported by all drivers. As an example, a gather write (multiple consecutive *i2c\_msg* buffers all configured for I2C\_MSG\_WRITE) may be packed into a single transaction by some drivers, but others may emit each fragment as a distinct write transaction, which will not produce the same behavior. See the documentation of struct *i2c\_msg* for limitations on support for multi-message bus transactions.

---

### Parameters

- dev – Pointer to the device structure for an I2C controller driver configured in master mode.
- msgs – Array of messages to transfer.
- num\_msgs – Number of messages to transfer.
- addr – Address of the I2C target device.

### Return values

- 0 – If successful.
- -EIO – General input / output error.

static inline int i2c\_transfer\_dt(const struct *i2c\_dt\_spec* \*spec, struct *i2c\_msg* \*msgs, uint8\_t num\_msgs)

Perform data transfer to another I2C device in master mode.

This is equivalent to:

```
i2c_transfer(spec->bus, msgs, num_msgs, spec->addr);
```

### Parameters

- spec – I2C specification from devicetree.
- msgs – Array of messages to transfer.

- `num_msgs` – Number of messages to transfer.

**Returns** a value from `i2c_transfer()`

```
int i2c_recover_bus(const struct device *dev)
```

Recover the I2C bus.

Attempt to recover the I2C bus.

#### Parameters

- `dev` – Pointer to the device structure for an I2C controller driver configured in master mode.

#### Return values

- 0 – If successful
- -EBUSY – If bus is not clear after recovery attempt.
- -EIO – General input / output error.
- -ENOSYS – If bus recovery is not implemented

```
static inline int i2c_slave_register(const struct device *dev, struct i2c_slave_config *cfg)
```

Registers the provided config as Slave device of a controller.

Enable I2C slave mode for the 'dev' I2C bus driver using the provided 'config' struct containing the functions and parameters to send bus events. The I2C slave will be registered at the address provided as 'address' struct member. Addressing mode - 7 or 10 bit - depends on the 'flags' struct member. Any I2C bus events related to the slave mode will be passed onto I2C slave device driver via a set of callback functions provided in the 'callbacks' struct member.

Most of the existing hardware allows simultaneous support for master and slave mode. This is however not guaranteed.

#### Parameters

- `dev` – Pointer to the device structure for an I2C controller driver configured in slave mode.
- `cfg` – Config struct with functions and parameters used by the I2C driver to send bus events

#### Return values

- 0 – Is successful
- -EINVAL – If parameters are invalid
- -EIO – General input / output error.
- -ENOSYS – If slave mode is not implemented

```
static inline int i2c_slave_unregister(const struct device *dev, struct i2c_slave_config *cfg)
```

Unregisters the provided config as Slave device.

This routine disables I2C slave mode for the 'dev' I2C bus driver using the provided 'config' struct containing the functions and parameters to send bus events.

#### Parameters

- `dev` – Pointer to the device structure for an I2C controller driver configured in slave mode.
- `cfg` – Config struct with functions and parameters used by the I2C driver to send bus events

#### Return values

- 0 – Is successful

- -EINVAL – If parameters are invalid
- -ENOSYS – If slave mode is not implemented

```
int i2c_slave_driver_register(const struct device *dev)
```

Instructs the I2C Slave device to register itself to the I2C Controller.

This routine instructs the I2C Slave device to register itself to the I2C Controller via its parent controller's *i2c\_slave\_register()* API.

#### Parameters

- dev – Pointer to the device structure for the I2C slave device (not itself an I2C controller).

#### Return values

- 0 – Is successful
- -EINVAL – If parameters are invalid
- -EIO – General input / output error.

```
int i2c_slave_driver_unregister(const struct device *dev)
```

Instructs the I2C Slave device to unregister itself from the I2C Controller.

This routine instructs the I2C Slave device to unregister itself from the I2C Controller via its parent controller's *i2c\_slave\_register()* API.

#### Parameters

- dev – Pointer to the device structure for the I2C slave device (not itself an I2C controller).

#### Return values

- 0 – Is successful
- -EINVAL – If parameters are invalid

```
static inline int i2c_write(const struct device *dev, const uint8_t *buf, uint32_t num_bytes,  
                           uint16_t addr)
```

Write a set amount of data to an I2C device.

This routine writes a set amount of data synchronously.

#### Parameters

- dev – Pointer to the device structure for an I2C controller driver configured in master mode.
- buf – Memory pool from which the data is transferred.
- num\_bytes – Number of bytes to write.
- addr – Address to the target I2C device for writing.

#### Return values

- 0 – If successful.
- -EIO – General input / output error.

```
static inline int i2c_write_dt(const struct i2c_dt_spec *spec, const uint8_t *buf, uint32_t  
                             num_bytes)
```

Write a set amount of data to an I2C device.

This is equivalent to:

```
i2c_write(spec->bus, buf, num_bytes, spec->addr);
```

**Parameters**

- `spec` – I2C specification from devicetree.
- `buf` – Memory pool from which the data is transferred.
- `num_bytes` – Number of bytes to write.

**Returns** a value from [`i2c\_write\(\)`](#)

```
static inline int i2c_read(const struct device *dev, uint8_t *buf, uint32_t num_bytes, uint16_t  
                        addr)
```

Read a set amount of data from an I2C device.

This routine reads a set amount of data synchronously.

**Parameters**

- `dev` – Pointer to the device structure for an I2C controller driver configured in master mode.
- `buf` – Memory pool that stores the retrieved data.
- `num_bytes` – Number of bytes to read.
- `addr` – Address of the I2C device being read.

**Return values**

- 0 – If successful.
- -EIO – General input / output error.

```
static inline int i2c_read_dt(const struct i2c\_dt\_spec *spec, uint8_t *buf, uint32_t num_bytes)
```

Read a set amount of data from an I2C device.

This is equivalent to:

```
i2c_read(spec->bus, buf, num_bytes, spec->addr);
```

**Parameters**

- `spec` – I2C specification from devicetree.
- `buf` – Memory pool that stores the retrieved data.
- `num_bytes` – Number of bytes to read.

**Returns** a value from [`i2c\_read\(\)`](#)

```
static inline int i2c_write_read(const struct device *dev, uint16_t addr, const void *write_buf,  
                               size_t num_write, void *read_buf, size_t num_read)
```

Write then read data from an I2C device.

This supports the common operation “this is what I want”, “now give it to me” transaction pair through a combined write-then-read bus transaction.

**Parameters**

- `dev` – Pointer to the device structure for an I2C controller driver configured in master mode.
- `addr` – Address of the I2C device
- `write_buf` – Pointer to the data to be written
- `num_write` – Number of bytes to write

- `read_buf` – Pointer to storage for read data
- `num_read` – Number of bytes to read

**Return values**

- 0 – if successful
- negative – on error.

```
static inline int i2c_write_read_dt(const struct i2c_dt_spec *spec, const void *write_buf, size_t
                                num_write, void *read_buf, size_t num_read)
```

Write then read data from an I2C device.

This is equivalent to:

```
i2c_write_read(spec->bus, spec->addr,
              write_buf, num_write,
              read_buf, num_read);
```

**Parameters**

- `spec` – I2C specification from devicetree.
- `write_buf` – Pointer to the data to be written
- `num_write` – Number of bytes to write
- `read_buf` – Pointer to storage for read data
- `num_read` – Number of bytes to read

**Returns** a value from *i2c\_write\_read()*

```
static inline int i2c_burst_read(const struct device *dev, uint16_t dev_addr, uint8_t start_addr,
                                uint8_t *buf, uint32_t num_bytes)
```

Read multiple bytes from an internal address of an I2C device.

This routine reads multiple bytes from an internal address of an I2C device synchronously.

Instances of this may be replaced by *i2c\_write\_read()*.

**Parameters**

- `dev` – Pointer to the device structure for an I2C controller driver configured in master mode.
- `dev_addr` – Address of the I2C device for reading.
- `start_addr` – Internal address from which the data is being read.
- `buf` – Memory pool that stores the retrieved data.
- `num_bytes` – Number of bytes being read.

**Return values**

- 0 – If successful.
- -EIO – General input / output error.

```
static inline int i2c_burst_read_dt(const struct i2c_dt_spec *spec, uint8_t start_addr, uint8_t
                                   *buf, uint32_t num_bytes)
```

Read multiple bytes from an internal address of an I2C device.

This is equivalent to:

```
i2c_burst_read(spec->bus, spec->addr, start_addr, buf, num_bytes);
```

**Parameters**

- `spec` – I2C specification from devicetree.
- `start_addr` – Internal address from which the data is being read.
- `buf` – Memory pool that stores the retrieved data.
- `num_bytes` – Number of bytes to read.

**Returns** a value from [`i2c\_burst\_read\(\)`](#)

```
static inline int i2c_burst_write(const struct device *dev, uint16_t dev_addr, uint8_t start_addr,  
                                const uint8_t *buf, uint32_t num_bytes)
```

Write multiple bytes to an internal address of an I2C device.

This routine writes multiple bytes to an internal address of an I2C device synchronously.

**Warning:** The combined write synthesized by this API may not be supported on all I2C devices. Uses of this API may be made more portable by replacing them with calls to [`i2c\_write\(\)`](#) passing a buffer containing the combined address and data.

**Parameters**

- `dev` – Pointer to the device structure for an I2C controller driver configured in master mode.
- `dev_addr` – Address of the I2C device for writing.
- `start_addr` – Internal address to which the data is being written.
- `buf` – Memory pool from which the data is transferred.
- `num_bytes` – Number of bytes being written.

**Return values**

- 0 – If successful.
- -EIO – General input / output error.

```
static inline int i2c_burst_write_dt(const struct i2c\_dt\_spec *spec, uint8_t start_addr, const  
                                   uint8_t *buf, uint32_t num_bytes)
```

Write multiple bytes to an internal address of an I2C device.

This is equivalent to:

```
i2c_burst_write(spec->bus, spec->addr, start_addr, buf, num_bytes);
```

**Parameters**

- `spec` – I2C specification from devicetree.
- `start_addr` – Internal address to which the data is being written.
- `buf` – Memory pool from which the data is transferred.
- `num_bytes` – Number of bytes being written.

**Returns** a value from [`i2c\_burst\_write\(\)`](#)

```
static inline int i2c_reg_read_byte(const struct device *dev, uint16_t dev_addr, uint8_t reg_addr,  
                                   uint8_t *value)
```

Read internal register of an I2C device.

This routine reads the value of an 8-bit internal register of an I2C device synchronously.

**Parameters**

- `dev` – Pointer to the device structure for an I2C controller driver configured in master mode.
- `dev_addr` – Address of the I2C device for reading.
- `reg_addr` – Address of the internal register being read.
- `value` – Memory pool that stores the retrieved register value.

**Return values**

- 0 – If successful.
- -EIO – General input / output error.

```
static inline int i2c_reg_read_byte_dt(const struct i2c_dt_spec *spec, uint8_t reg_addr, uint8_t *value)
```

Read internal register of an I2C device.

This is equivalent to:

```
i2c_reg_read_byte(spec->bus, spec->addr, reg_addr, value);
```

**Parameters**

- `spec` – I2C specification from devicetree.
- `reg_addr` – Address of the internal register being read.
- `value` – Memory pool that stores the retrieved register value.

**Returns** a value from *i2c\_reg\_read\_byte()*

```
static inline int i2c_reg_write_byte(const struct device *dev, uint16_t dev_addr, uint8_t reg_addr, uint8_t value)
```

Write internal register of an I2C device.

This routine writes a value to an 8-bit internal register of an I2C device synchronously.

---

**Note:** This function internally combines the register and value into a single bus transaction.

---

**Parameters**

- `dev` – Pointer to the device structure for an I2C controller driver configured in master mode.
- `dev_addr` – Address of the I2C device for writing.
- `reg_addr` – Address of the internal register being written.
- `value` – Value to be written to internal register.

**Return values**

- 0 – If successful.
- -EIO – General input / output error.

```
static inline int i2c_reg_write_byte_dt(const struct i2c_dt_spec *spec, uint8_t reg_addr, uint8_t value)
```

Write internal register of an I2C device.

This is equivalent to:

```
i2c_reg_write_byte(spec->bus, spec->addr, reg_addr, value);
```

**Parameters**

- `spec` – I2C specification from devicetree.
- `reg_addr` – Address of the internal register being written.
- `value` – Value to be written to internal register.

**Returns** a value from [`i2c\_reg\_write\_byte\(\)`](#)

```
static inline int i2c_reg_update_byte(const struct device *dev, uint8_t dev_addr, uint8_t  
                                     reg_addr, uint8_t mask, uint8_t value)
```

Update internal register of an I2C device.

This routine updates the value of a set of bits from an 8-bit internal register of an I2C device synchronously.

---

**Note:** If the calculated new register value matches the value that was read this function will not generate a write operation.

---

**Parameters**

- `dev` – Pointer to the device structure for an I2C controller driver configured in master mode.
- `dev_addr` – Address of the I2C device for updating.
- `reg_addr` – Address of the internal register being updated.
- `mask` – Bitmask for updating internal register.
- `value` – Value for updating internal register.

**Return values**

- 0 – If successful.
- -EIO – General input / output error.

```
static inline int i2c_reg_update_byte_dt(const struct i2c\_dt\_spec *spec, uint8_t reg_addr,  
                                         uint8_t mask, uint8_t value)
```

Update internal register of an I2C device.

This is equivalent to:

```
i2c_reg_update_byte(spec->bus, spec->addr, reg_addr, mask, value);
```

**Parameters**

- `spec` – I2C specification from devicetree.
- `reg_addr` – Address of the internal register being updated.
- `mask` – Bitmask for updating internal register.
- `value` – Value for updating internal register.

**Returns** a value from [`i2c\_reg\_update\_byte\(\)`](#)

```
void i2c_dump_msgs(const char *name, const struct i2c_msg *msgs, uint8_t num_msgs, uint16_t
addr)
```

Dump out an I2C message.

Dumps out a list of I2C messages. For any that are writes (W), the data is displayed in hex.

It looks something like this (with name “testing”):

```
D: I2C msg: testing, addr=56 D: W len=01: D: contents: D: 06 |. D: W len=0e: D: contents:
D: 00 01 02 03 04 05 06 07 |..... D: 08 09 0a 0b 0c 0d |.....
```

#### Parameters

- `name` – Name of this dump, displayed at the top.
- `msgs` – Array of messages to dump.
- `num_msgs` – Number of messages to dump.
- `addr` – Address of the I2C target device.

```
struct i2c_dt_spec
```

*#include <i2c.h>* Complete I2C DT information.

**Param `bus`** is the I2C bus

**Param `addr`** is the slave address

```
struct i2c_msg
```

*#include <i2c.h>* One I2C Message.

This defines one I2C message to transact on the I2C bus.

---

**Note:** Some of the configurations supported by this API may not be supported by specific SoC I2C hardware implementations, in particular features related to bus transactions intended to read or write data from different buffers within a single transaction. Invocations of *i2c\_transfer()* may not indicate an error when an unsupported configuration is encountered. In some cases drivers will generate separate transactions for each message fragment, with or without presence of *I2C\_MSG\_RESTART* in *flags*.

---

#### Public Members

```
uint8_t *buf
```

Data buffer in bytes

```
uint32_t len
```

Length of buffer in bytes

```
uint8_t flags
```

Flags for this message

```
struct i2c_slave_callbacks
```

*#include <i2c.h>* Structure providing callbacks to be implemented for devices that supports the I2C slave API.

This structure may be shared by multiple devices that implement the same API at different addresses on the bus.

```
struct i2c_slave_config
```

*#include <i2c.h>* Structure describing a device that supports the I2C slave API.

Instances of this are passed to the *i2c\_slave\_register()* and *i2c\_slave\_unregister()* functions to indicate addition and removal of a slave device, respective.

Fields other than `node` must be initialized by the module that implements the device behavior prior to passing the object reference to *i2c\_slave\_register()*.

### Public Members

```
sys_snode_t node
```

Private, do not modify

```
uint8_t flags
```

Flags for the slave device defined by `I2C_SLAVE_FLAGS_*` constants

```
uint16_t address
```

Address for this slave device

```
const struct i2c_slave_callbacks *callbacks
```

Callback functions

```
struct i2c_client_config
```

*#include <i2c.h>*

## 7.21.15 IPM

### Overview

### API Reference

```
group ipm_interface
```

IPM Interface.

### Typedefs

```
typedef void (*ipm_callback_t)(const struct device *ipmdev, void *user_data, uint32_t id,  
volatile void *data)
```

Callback API for incoming IPM messages.

These callbacks execute in interrupt context. Therefore, use only interrupt-safe APIs. Registration of callbacks is done via *ipm\_register\_callback*

**Param ipmdev** Driver instance

**Param user\_data** Pointer to some private data provided at registration time.

**Param id** Message type identifier.

**Param data** Message data pointer. The correct amount of data to read out must be inferred using the message id/upper level protocol.

```
typedef int (*ipm_send_t)(const struct device *ipmdev, int wait, uint32_t id, const void *data, int size)
```

Callback API to send IPM messages.

See [ipm\\_send\(\)](#) for argument definitions.

```
typedef int (*ipm_max_data_size_get_t)(const struct device *ipmdev)
```

Callback API to get maximum data size.

See [ipm\\_max\\_data\\_size\\_get\(\)](#) for argument definitions.

```
typedef uint32_t (*ipm_max_id_val_get_t)(const struct device *ipmdev)
```

Callback API to get the ID's maximum value.

See [ipm\\_max\\_id\\_val\\_get\(\)](#) for argument definitions.

```
typedef void (*ipm_register_callback_t)(const struct device *port, ipm_callback_t cb, void *user_data)
```

Callback API upon registration.

See [ipm\\_register\\_callback\(\)](#) for argument definitions.

```
typedef int (*ipm_set_enabled_t)(const struct device *ipmdev, int enable)
```

Callback API upon enablement of interrupts.

See [ipm\\_set\\_enabled\(\)](#) for argument definitions.

## Functions

```
int ipm_send(const struct device *ipmdev, int wait, uint32_t id, const void *data, int size)
```

Try to send a message over the IPM device.

A message is considered consumed once the remote interrupt handler finishes. If there is deferred processing on the remote side, or if outgoing messages must be queued and wait on an event/semaphore, a high-level driver can implement that.

There are constraints on how much data can be sent or the maximum value of id. Use the [ipm\\_max\\_data\\_size\\_get](#) and [ipm\\_max\\_id\\_val\\_get](#) routines to determine them.

The *size* parameter is used only on the sending side to determine the amount of data to put in the message registers. It is not passed along to the receiving side. The upper-level protocol dictates the amount of data read back.

### Parameters

- *ipmdev* – Driver instance
- *wait* – If nonzero, busy-wait for remote to consume the message. The message is considered consumed once the remote interrupt handler finishes. If there is deferred processing on the remote side, or you would like to queue outgoing messages and wait on an event/semaphore, you can implement that in a high-level driver
- *id* – Message identifier. Values are constrained by [ipm\\_max\\_data\\_size\\_get](#) since many boards only allow for a subset of bits in a 32-bit register to store the ID.
- *data* – Pointer to the data sent in the message.
- *size* – Size of the data.

### Return values

- -EBUSY – If the remote hasn't yet read the last data sent.
- -EMSGSIZE – If the supplied data size is unsupported by the driver.
- -EINVAL – If there was a bad parameter, such as: too-large id value. or the device isn't an outbound IPM channel.
- 0 – On success.

```
static inline void ipm_register_callback(const struct device *ipmdev, ipm_callback_t cb, void  
                                     *user_data)
```

Register a callback function for incoming messages.

#### Parameters

- ipmdev – Driver instance pointer.
- cb – Callback function to execute on incoming message interrupts.
- user\_data – Application-specific data pointer which will be passed to the callback function when executed.

```
int ipm_max_data_size_get(const struct device *ipmdev)
```

Return the maximum number of bytes possible in an outbound message.

IPM implementations vary on the amount of data that can be sent in a single message since the data payload is typically stored in registers.

#### Parameters

- ipmdev – Driver instance pointer.

**Returns** Maximum possible size of a message in bytes.

```
uint32_t ipm_max_id_val_get(const struct device *ipmdev)
```

Return the maximum id value possible in an outbound message.

Many IPM implementations store the message's ID in a register with some bits reserved for other uses.

#### Parameters

- ipmdev – Driver instance pointer.

**Returns** Maximum possible value of a message ID.

```
int ipm_set_enabled(const struct device *ipmdev, int enable)
```

Enable interrupts and callbacks for inbound channels.

#### Parameters

- ipmdev – Driver instance pointer.
- enable – Set to 0 to disable and to nonzero to enable.

#### Return values

- 0 – On success.
- -EINVAL – If it isn't an inbound channel.

```
struct ipm_driver_api  
#include <ipm.h>
```

## 7.21.16 KSCAN

### Overview

The `kscan` driver (keyboard scan matrix) is used for detecting a key press in a connected matrix keyboard or any device with buttons such as joysticks. Typically, matrix keyboards are implemented using a two-dimensional configuration in order to sense several keys. This allows interfacing to many keys through fewer physical pins. Keyboard matrix drivers read the rows while applying power through the columns one at a time with the purpose of detecting key events. There is no correlation between the physical and electrical layout of keys. For, example, the physical layout may be one array of 16 or fewer keys, which may be electrically connected to a 4 x 4 array. In addition, key values are defined by a keymap provided by the keyboard manufacturer.

### Configuration Options

Related configuration options:

- `:kconfig: `CONFIG_KSCAN``

### API Reference

*group* `kscan_interface`

KSCAN APIs.

#### Typedefs

```
typedef void (*kscan_callback_t)(const struct device *dev, uint32_t row, uint32_t column, bool pressed)
```

Keyboard scan callback called when user press/release a key on a matrix keyboard.

**Param dev** Pointer to the device structure for the driver instance.

**Param row** Describes row change.

**Param column** Describes column change.

**Param pressed** Describes the kind of key event.

#### Functions

```
int kscan_config(const struct device *dev, kscan_callback_t callback)
```

Configure a Keyboard scan instance.

##### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `callback` – called when keyboard devices reply to to a keyboard event such as key pressed/released.

##### Return values

- 0 – If successful.
- Negative – `errno` code if failure.

```
int kscan_enable_callback(const struct device *dev)
```

Enables callback.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.

#### Return values

- 0 – If successful.
- Negative – `errno` code if failure.

```
int kscan_disable_callback(const struct device *dev)
```

Disables callback.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.

#### Return values

- 0 – If successful.
- Negative – `errno` code if failure.

## 7.21.17 LED

### Overview

The LED API provides access to Light Emitting Diodes, both in individual and strip form.

### Configuration Options

Related configuration options:

- `:kconfig: `CONFIG_LED``
- `:kconfig: `CONFIG_LED_STRIP``

### API Reference

#### LED

*group* `led_interface`

LED Interface.

#### Typedefs

```
typedef int (*led_api_blink)(const struct device *dev, uint32_t led, uint32_t delay_on, uint32_t delay_off)
```

Callback API for blinking an LED.

#### See also:

[\*led\\_blink\(\)\*](#) for argument descriptions.

```
typedef int (*led_api_get_info)(const struct device *dev, uint32_t led, const struct led\_info
**info)
```

Optional API callback to get LED information.

**See also:**

[led\\_get\\_info\(\)](#) for argument descriptions.

```
typedef int (*led_api_set_brightness)(const struct device *dev, uint32_t led, uint8_t value)
```

Callback API for setting brightness of an LED.

**See also:**

[led\\_set\\_brightness\(\)](#) for argument descriptions.

```
typedef int (*led_api_set_color)(const struct device *dev, uint32_t led, uint8_t num_colors,
const uint8_t *color)
```

Optional API callback to set the colors of a LED.

**See also:**

[led\\_set\\_color\(\)](#) for argument descriptions.

```
typedef int (*led_api_on)(const struct device *dev, uint32_t led)
```

Callback API for turning on an LED.

**See also:**

[led\\_on\(\)](#) for argument descriptions.

```
typedef int (*led_api_off)(const struct device *dev, uint32_t led)
```

Callback API for turning off an LED.

**See also:**

[led\\_off\(\)](#) for argument descriptions.

```
typedef int (*led_api_write_channels)(const struct device *dev, uint32_t start_channel,
uint32_t num_channels, const uint8_t *buf)
```

Callback API for writing a strip of LED channels.

**See also:**

[led\\_api\\_write\\_channels\(\)](#) for arguments descriptions.

## Functions

```
int led_blink(const struct device *dev, uint32_t led, uint32_t delay_on, uint32_t delay_off)
```

Blink an LED.

This optional routine starts blinking a LED forever with the given time period.

**Parameters**

- `dev` – LED device
- `led` – LED number
- `delay_on` – Time period (in milliseconds) an LED should be ON
- `delay_off` – Time period (in milliseconds) an LED should be OFF

**Returns** 0 on success, negative on error

```
int led_get_info(const struct device *dev, uint32_t led, const struct led\_info **info)
```

Get LED information.

This optional routine provides information about a LED.

**Parameters**

- `dev` – LED device
- `led` – LED number
- `info` – Pointer to a pointer filled with LED information

**Returns** 0 on success, negative on error

```
int led_set_brightness(const struct device *dev, uint32_t led, uint8_t value)
```

Set LED brightness.

This optional routine sets the brightness of a LED to the given value. Calling this function after [led\\_blink\(\)](#) won't affect blinking.

LEDs which can only be turned on or off may provide this function. These should simply turn the LED on if `value` is nonzero, and off if `value` is zero.

**Parameters**

- `dev` – LED device
- `led` – LED number
- `value` – Brightness value to set in percent

**Returns** 0 on success, negative on error

```
int led_write_channels(const struct device *dev, uint32_t start_channel, uint32_t  
                      num_channels, const uint8_t *buf)
```

Write/update a strip of LED channels.

This optional routine writes a strip of LED channels to the given array of levels. Therefore it can be used to configure several LEDs at the same time.

Calling this function after [led\\_blink\(\)](#) won't affect blinking.

**Parameters**

- `dev` – LED device
- `start_channel` – Absolute number (i.e. not relative to a LED) of the first channel to update.
- `num_channels` – The number of channels to write/update.
- `buf` – array of values to configure the channels with. `num_channels` entries must be provided.

**Returns** 0 on success, negative on error

```
int led_set_channel(const struct device *dev, uint32_t channel, uint8_t value)
```

Set a single LED channel.

This optional routine sets a single LED channel to the given value.

Calling this function after [led\\_blink\(\)](#) won't affect blinking.

**Parameters**

- `dev` – LED device
- `channel` – Absolute channel number (i.e. not relative to a LED)
- `value` – Value to configure the channel with

**Returns** 0 on success, negative on error

```
int led_set_color(const struct device *dev, uint32_t led, uint8_t num_colors, const uint8_t *color)
```

Set LED color.

This routine configures all the color channels of a LED with the given color array.

Calling this function after [led\\_blink\(\)](#) won't affect blinking.

**Parameters**

- `dev` – LED device
- `led` – LED number
- `num_colors` – Number of colors in the array.
- `color` – Array of colors. It must be ordered following the color mapping of the LED controller. See the `color_mapping` member in struct [led\\_info](#).

**Returns** 0 on success, negative on error

```
int led_on(const struct device *dev, uint32_t led)
```

Turn on an LED.

This routine turns on an LED

**Parameters**

- `dev` – LED device
- `led` – LED number

**Returns** 0 on success, negative on error

```
int led_off(const struct device *dev, uint32_t led)
```

Turn off an LED.

This routine turns off an LED

**Parameters**

- `dev` – LED device
- `led` – LED number

**Returns** 0 on success, negative on error

```
struct led_info
```

*#include <led.h>* LED information structure.

This structure gathers useful information about LED controller.

**Param label** LED label.

**Param num\_colors** Number of colors per LED.

**Param index** Index of the LED on the controller.

**Param color\_mapping** Mapping of the LED colors.

struct led\_driver\_api

*#include <led.h>* LED driver API.

## LED Strip

group led\_strip\_interface

LED Strip Interface.

## Typedefs

typedef int (\*led\_api\_update\_rgb)(const struct [device](#) \*dev, struct [led\\_rgb](#) \*pixels, size\_t num\_pixels)

Callback API for updating an RGB LED strip.

**See also:**

[led\\_strip\\_update\\_rgb\(\)](#) for argument descriptions.

typedef int (\*led\_api\_update\_channels)(const struct [device](#) \*dev, uint8\_t \*channels, size\_t num\_channels)

Callback API for updating channels without an RGB interpretation.

**See also:**

[led\\_strip\\_update\\_channels\(\)](#) for argument descriptions.

## Functions

static inline int led\_strip\_update\_rgb(const struct [device](#) \*dev, struct [led\\_rgb](#) \*pixels, size\_t num\_pixels)

Update an LED strip made of RGB pixels.

Important: This routine may overwrite *pixels*.

This routine immediately updates the strip display according to the given pixels array.

**Warning:** May overwrite *pixels*

### Parameters

- *dev* – LED strip device
- *pixels* – Array of pixel data
- *num\_pixels* – Length of pixels array

**Returns** 0 on success, negative on error

```
static inline int led_strip_update_channels(const struct device *dev, uint8_t *channels, size_t
                                         num_channels)
```

Update an LED strip on a per-channel basis.

Important: This routine may overwrite *channels*.

This routine immediately updates the strip display according to the given channels array. Each channel byte corresponds to an individually addressable color channel or LED. Channels are updated linearly in strip order.

**Warning:** May overwrite *channels*

#### Parameters

- *dev* – LED strip device
- *channels* – Array of per-channel data
- *num\_channels* – Length of channels array

**Returns** 0 on success, negative on error

```
struct led_rgb
```

*#include <led\_strip.h>* Color value for a single RGB LED.

Individual strip drivers may ignore lower-order bits if their resolution in any channel is less than a full byte.

#### Public Members

```
uint8_t r
```

Red channel

```
uint8_t g
```

Green channel

```
uint8_t b
```

Blue channel

```
struct led_strip_driver_api
```

*#include <led\_strip.h>* LED strip driver API.

This is the mandatory API any LED strip driver needs to expose.

## 7.21.19 PWM

### Overview

### API Reference

group pwm\_interface  
PWM Interface.

### PWM capture configuration flags

PWM\_CAPTURE\_TYPE\_PERIOD

PWM pin capture captures period.

PWM\_CAPTURE\_TYPE\_PULSE

PWM pin capture captures pulse width.

PWM\_CAPTURE\_TYPE\_BOTH

PWM pin capture captures both period and pulse width.

PWM\_CAPTURE\_MODE\_SINGLE

PWM pin capture captures a single period/pulse width.

PWM\_CAPTURE\_MODE\_CONTINUOUS

PWM pin capture captures period/pulse width continuously.

## Typedefs

typedef uint8\_t pwm\_flags\_t

Provides a type to hold PWM configuration flags.

typedef int (\*pwm\_pin\_set\_t)(const struct [device](#) \*dev, uint32\_t pwm, uint32\_t period\_cycles, uint32\_t pulse\_cycles, [pwm\\_flags\\_t](#) flags)

Callback API upon setting the pin See [pwm\\_pin\\_set\\_cycles\(\)](#) for argument description.

typedef void (\*pwm\_capture\_callback\_handler\_t)(const struct [device](#) \*dev, uint32\_t pwm, uint32\_t period\_cycles, uint32\_t pulse\_cycles, int status, void \*user\_data)

PWM capture callback handler function signature.

---

**Note:** The callback handler will be called in interrupt context.

---

---

**Note:** **:kconfig: `CONFIG\_PWM\_CAPTURE`** must be selected to enable PWM capture support.

---

**Param dev** Pointer to the device structure for the driver instance.

**Param pwm** PWM pin.

**Param period\_cycles** Captured PWM period width (in clock cycles). HW specific.

**Param pulse\_cycles** Captured PWM pulse width (in clock cycles). HW specific.

**Param status** Status for the PWM capture (0 if no error, negative errno otherwise.  
See [pwm\\_pin\\_capture\\_cycles\(\)](#) return value descriptions for details).

**Param user\_data** User data passed to [pwm\\_pin\\_configure\\_capture\(\)](#)

typedef int (\*pwm\_pin\_configure\_capture\_t)(const struct [device](#) \*dev, uint32\_t pwm, [pwm\\_flags\\_t](#) flags, [pwm\\_capture\\_callback\\_handler\\_t](#) cb, void \*user\_data)

Callback API upon configuring PWM pin capture See [pwm\\_pin\\_configure\\_capture\(\)](#) for argument description.

typedef int (\*pwm\_pin\_enable\_capture\_t)(const struct [device](#) \*dev, uint32\_t pwm)

Callback API upon enabling PWM pin capture See [pwm\\_pin\\_enable\\_capture\(\)](#) for argument description.

```
typedef int (*pwm_pin_disable_capture_t)(const struct device *dev, uint32_t pwm)
```

Callback API upon disabling PWM pin capture See [pwm\\_pin\\_disable\\_capture\(\)](#) for argument description.

```
typedef int (*pwm_get_cycles_per_sec_t)(const struct device *dev, uint32_t pwm, uint64_t *cycles)
```

Callback API upon getting cycles per second See [pwm\\_get\\_cycles\\_per\\_sec\(\)](#) for argument description.

## Functions

```
int pwm_pin_set_cycles(const struct device *dev, uint32_t pwm, uint32_t period, uint32_t pulse, pwm\_flags\_t flags)
```

Set the period and pulse width for a single PWM output.

The PWM period and pulse width will synchronously be set to the new values without glitches in the PWM signal, but the call will not block for the change to take effect.

Passing 0 as pulse will cause the pin to be driven to a constant inactive level. Passing a non-zero pulse equal to period will cause the pin to be driven to a constant active level.

---

**Note:** Not all PWM controllers support synchronous, glitch-free updates of the PWM period and pulse width. Depending on the hardware, changing the PWM period and/or pulse width may cause a glitch in the generated PWM signal.

---

---

**Note:** Some multi-channel PWM controllers share the PWM period across all channels. Depending on the hardware, changing the PWM period for one channel may affect the PWM period for the other channels of the same PWM controller.

---

### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `pwm` – PWM pin.
- `period` – Period (in clock cycle) set to the PWM. HW specific.
- `pulse` – Pulse width (in clock cycle) set to the PWM. HW specific.
- `flags` – Flags for pin configuration (polarity).

### Return values

- 0 – If successful.
- Negative – errno code if failure.

```
static inline int pwm_pin_configure_capture(const struct device *dev, uint32_t pwm, pwm\_flags\_t flags, pwm\_capture\_callback\_handler\_t cb, void *user_data)
```

Configure PWM period/pulse width capture for a single PWM input.

After configuring PWM capture using this function, the capture can be enabled/disabled using [pwm\\_pin\\_enable\\_capture\(\)](#) and [pwm\\_pin\\_disable\\_capture\(\)](#).

---

**Note:** This API function cannot be invoked from user space due to the use of a function callback. In user space, one of the simpler API functions ([pwm\\_pin\\_capture\\_cycles\(\)](#), [pwm\\_pin\\_capture\\_usec\(\)](#), or [pwm\\_pin\\_capture\\_nsec\(\)](#)) can be used instead.

---

---

**Note:** `:kconfig: `CONFIG_PWM_CAPTURE`` must be selected for this function to be available.

---

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `pwm` – PWM pin.
- `flags` – PWM capture flags
- `cb` – Application callback handler function to be called upon capture
- `user_data` – User data to pass to the application callback handler function

#### Return values

- `-EINVAL` – if invalid function parameters were given
- `-ENOSYS` – if PWM capture is not supported or the given flags are not supported
- `-EIO` – if IO error occurred while configuring
- `-EBUSY` – if PWM capture is already in progress

```
int pwm_pin_enable_capture(const struct device *dev, uint32_t pwm)
```

Enable PWM period/pulse width capture for a single PWM input.

The PWM pin must be configured using [pwm\\_pin\\_configure\\_capture\(\)](#) prior to calling this function.

---

**Note:** `:kconfig: `CONFIG_PWM_CAPTURE`` must be selected for this function to be available.

---

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `pwm` – PWM pin.

#### Return values

- `0` – If successful.
- `-EINVAL` – if invalid function parameters were given
- `-ENOSYS` – if PWM capture is not supported
- `-EIO` – if IO error occurred while enabling PWM capture
- `-EBUSY` – if PWM capture is already in progress

```
int pwm_pin_disable_capture(const struct device *dev, uint32_t pwm)
```

Disable PWM period/pulse width capture for a single PWM input.

---

**Note:** `:kconfig: `CONFIG_PWM_CAPTURE`` must be selected for this function to be available.

---

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.
- `pwm` – PWM pin.

**Return values**

- 0 – If successful.
- -EINVAL – if invalid function parameters were given
- -ENOSYS – if PWM capture is not supported
- -EIO – if IO error occurred while disabling PWM capture

```
int pwm_pin_capture_cycles(const struct device *dev, uint32_t pwm, pwm_flags_t flags, uint32_t
                        *period, uint32_t *pulse, k_timeout_t timeout)
```

Capture a single PWM period/pulse width in clock cycles for a single PWM input.

This API function wraps calls to `pwm_pin_configure_capture()`, `pwm_pin_enable_capture()`, and `pwm_pin_disable_capture()` and passes the capture result to the caller. The function is blocking until either the PWM capture is completed or a timeout occurs.

---

**Note:** `:kconfig: 'CONFIG_PWM_CAPTURE'` must be selected for this function to be available.

---

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.
- `pwm` – PWM pin.
- `flags` – PWM capture flags.
- `period` – Pointer to the memory to store the captured PWM period width (in clock cycles). HW specific.
- `pulse` – Pointer to the memory to store the captured PWM pulse width (in clock cycles). HW specific.
- `timeout` – Waiting period for the capture to complete.

**Return values**

- 0 – If successful.
- -EBUSY – PWM capture already in progress.
- -EAGAIN – Waiting period timed out.
- -EIO – IO error while capturing.
- -ERANGE – If result is too large.

```
int pwm_get_cycles_per_sec(const struct device *dev, uint32_t pwm, uint64_t *cycles)
```

Get the clock rate (cycles per second) for a single PWM output.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.
- `pwm` – PWM pin.
- `cycles` – Pointer to the memory to store clock rate (cycles per sec). HW specific.

**Return values**

- 0 – If successful.
- Negative – errno code if failure.

```
static inline int pwm_pin_set_usec(const struct device *dev, uint32_t pwm, uint32_t period,  
                                uint32_t pulse, pwm_flags_t flags)
```

Set the period and pulse width for a single PWM output.

#### Parameters

- dev – Pointer to the device structure for the driver instance.
- pwm – PWM pin.
- period – Period (in microseconds) set to the PWM.
- pulse – Pulse width (in microseconds) set to the PWM.
- flags – Flags for pin configuration (polarity).

#### Return values

- 0 – If successful.
- Negative – errno code if failure.

```
static inline int pwm_pin_set_nsec(const struct device *dev, uint32_t pwm, uint32_t period,  
                                uint32_t pulse, pwm_flags_t flags)
```

Set the period and pulse width for a single PWM output.

#### Parameters

- dev – Pointer to the device structure for the driver instance.
- pwm – PWM pin.
- period – Period (in nanoseconds) set to the PWM.
- pulse – Pulse width (in nanoseconds) set to the PWM.
- flags – Flags for pin configuration (polarity).

#### Return values

- 0 – If successful.
- Negative – errno code if failure.

```
static inline int pwm_pin_cycles_to_usec(const struct device *dev, uint32_t pwm, uint32_t  
                                       cycles, uint64_t *usec)
```

Convert from PWM cycles to microseconds.

#### Parameters

- dev – Pointer to the device structure for the driver instance.
- pwm – PWM pin.
- cycles – Cycles to be converted.
- usec – Pointer to the memory to store calculated usec.

#### Return values

- 0 – If successful.
- -EIO – If cycles per second cannot be determined.
- -ERANGE – If result is too large.

```
static inline int pwm_pin_cycles_to_nsec(const struct device *dev, uint32_t pwm, uint32_t
                                         cycles, uint64_t *nsec)
```

Convert from PWM cycles to nanoseconds.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `pwm` – PWM pin.
- `cycles` – Cycles to be converted.
- `nsec` – Pointer to the memory to store the calculated nsec.

#### Return values

- 0 – If successful.
- -EIO – If cycles per second cannot be determined.
- -ERANGE – If result is too large.

```
static inline int pwm_pin_capture_usec(const struct device *dev, uint32_t pwm, pwm_flags_t
                                       flags, uint64_t *period, uint64_t *pulse, k_timeout_t
                                       timeout)
```

Capture a single PWM period/pulse width in microseconds for a single PWM input.

This API function wraps calls to `pwm_pin_capture_cycles()` and `pwm_pin_cycles_to_usec()` and passes the capture result to the caller. The function is blocking until either the PWM capture is completed or a timeout occurs.

---

**Note:** `:kconfig: `CONFIG_PWM_CAPTURE`` must be selected for this function to be available.

---

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `pwm` – PWM pin.
- `flags` – PWM capture flags.
- `period` – Pointer to the memory to store the captured PWM period width (in usec).
- `pulse` – Pointer to the memory to store the captured PWM pulse width (in usec).
- `timeout` – Waiting period for the capture to complete.

#### Return values

- 0 – If successful.
- -EBUSY – PWM capture already in progress.
- -EAGAIN – Waiting period timed out.
- -EIO – IO error while capturing.
- -ERANGE – If result is too large.

```
static inline int pwm_pin_capture_nsec(const struct device *dev, uint32_t pwm, pwm_flags_t
                                       flags, uint64_t *period, uint64_t *pulse, k_timeout_t
                                       timeout)
```

Capture a single PWM period/pulse width in nanoseconds for a single PWM input.

This API function wraps calls to `pwm_pin_capture_cycles()` and `pwm_pin_cycles_to_nsec()` and passes the capture result to the caller. The function is blocking until either the PWM capture is completed or a timeout occurs.

---

**Note:** `:kconfig: `CONFIG_PWM_CAPTURE`` must be selected for this function to be available.

---

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `pwm` – PWM pin.
- `flags` – PWM capture flags.
- `period` – Pointer to the memory to store the captured PWM period width (in nsec).
- `pulse` – Pointer to the memory to store the captured PWM pulse width (in nsec).
- `timeout` – Waiting period for the capture to complete.

#### Return values

- 0 – If successful.
- `-EBUSY` – PWM capture already in progress.
- `-EAGAIN` – Waiting period timed out.
- `-EIO` – IO error while capturing.
- `-ERANGE` – If result is too large.

```
struct pwm_driver_api
#include <pwm.h> PWM driver API definition.
```

## 7.21.20 PS/2

### Overview

The PS/2 connector first hit the market in 1987 on IBM's desktop PC line of the same name before becoming an industry-wide standard for mouse and keyboard connections. Starting around 2007, USB superseded PS/2 and is the modern peripheral device connection standard. For legacy support on boards with a PS/2 connector, Zephyr provides these PS/2 driver APIs.

### Configuration Options

Related configuration options:

- `:kconfig: `CONFIG_PS2``

## API Reference

group ps2\_interface

PS/2 Driver APIs.

### Typedefs

```
typedef void (*ps2_callback_t)(const struct device *dev, uint8_t data)
```

PS/2 callback called when user types or click a mouse.

**Param dev** Pointer to the device structure for the driver instance.

**Param data** Data byte passed pack to the user.

### Functions

```
int ps2_config(const struct device *dev, ps2_callback_t callback_isr)
```

Configure a ps2 instance.

#### Parameters

- **dev** – Pointer to the device structure for the driver instance.
- **callback\_isr** – called when PS/2 devices reply to a configuration command or when a mouse/keyboard send data to the client application.

#### Return values

- 0 – If successful.
- Negative – errno code if failure.

```
int ps2_write(const struct device *dev, uint8_t value)
```

Write to PS/2 device.

#### Parameters

- **dev** – Pointer to the device structure for the driver instance.
- **value** – Data for the PS2 device.

#### Return values

- 0 – If successful.
- Negative – errno code if failure.

```
int ps2_read(const struct device *dev, uint8_t *value)
```

Read slave-to-host values from PS/2 device.

#### Parameters

- **dev** – Pointer to the device structure for the driver instance.
- **value** – Pointer used for reading the PS/2 device.

#### Return values

- 0 – If successful.
- Negative – errno code if failure.

```
int ps2_enable_callback(const struct device *dev)
```

Enables callback.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.

#### Return values

- 0 – If successful.
- Negative – errno code if failure.

```
int ps2_disable_callback(const struct device *dev)
```

Disables callback.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.

#### Return values

- 0 – If successful.
- Negative – errno code if failure.

## 7.21.21 PECI

### Overview

The Platform Environment Control Interface, abbreviated as PECE, is a thermal management standard introduced in 2006 with the Intel Core 2 Duo Microprocessors. The PECE interface allows external devices to read processor temperature, perform processor manageability functions, and manage processor interface tuning and diagnostics. The PECE bus driver APIs enable the interaction between Embedded Microcontrollers and CPUs.

### Configuration Options

## Functions

int peci\_config(const struct [device](#) \*dev, uint32\_t bitrate)

Configures the Peci interface.

### Parameters

- dev – Pointer to the device structure for the driver instance.
- bitrate – the selected expressed in Kbps. command or when an event needs to be sent to the client application.

### Return values

- 0 – If successful.
- Negative – errno code if failure.

int peci\_enable(const struct [device](#) \*dev)

Enable Peci interface.

### Parameters

- dev – Pointer to the device structure for the driver instance.

### Return values

- 0 – If successful.
- Negative – errno code if failure.

int peci\_disable(const struct [device](#) \*dev)

Disable Peci interface.

### Parameters

- dev – Pointer to the device structure for the driver instance.

### Return values

- 0 – If successful.
- Negative – errno code if failure.

int peci\_transfer(const struct [device](#) \*dev, struct [peci\\_msg](#) \*msg)

Performs a Peci transaction.

### Parameters

- dev – Pointer to the device structure for the driver instance.
- msg – Structure representing a Peci transaction.

### Return values

- 0 – If successful.
- Negative – errno code if failure.

struct peci\_buf

*#include <peci.h>* Peci buffer structure.

Note: Frame check sequence byte is added into rx buffer, need to allocate an additional byte for this in rx buffer.

**Param buf** is a valid pointer on a data buffer, or NULL otherwise.

**Param len** is the length of the data buffer expected to received without considering the frame check sequence byte.

struct peci\_msg

*#include <peci.h>* Peci transaction packet format.

### Public Members

uint8\_t addr

Client address

enum [peci\\_command\\_code](#) cmd\_code

Command code

struct [peci\\_buf](#) tx\_buffer

Pointer to buffer of write data

struct [peci\\_buf](#) rx\_buffer

Pointer to buffer of read data

uint8\_t flags

PECI msg flags

## 7.21.22 Regulators

This subsystem provides control of voltage and current regulators. A common example is a GPIO that controls a transistor that supplies current to a device that is not always needed.

Conceptually regulators have two modes: off and on. A transition between modes may involve a time delay, so operations on regulators are inherently asynchronous. To maximize flexibility the [On-Off Manager](#) infrastructure is used in the generic API for the regulator subsystem. Nodes with a devicetree compatible of `regulator-fixed` are the most common flexible regulators.

In some cases the transitions are close enough to instantaneous that the asynchronous driver implementation is not needed, and the resource cost in RAM is not justified. Such a regulator still uses the asynchronous API, but may be implemented internally in a way that ensures the result of the operation is presented before the transition completes. Zephyr recognizes devicetree nodes with a compatible of `regulator-fixed-sync` as devices with synchronous transitions.

The `vin-supply` devicetree property is used to identify the regulator(s) that a devicetree node directly depends on. Within the driver for the node the regulator API is used to issue requests for power when the device is to be active, and release the power request when the device shuts down.

The simplest case where a regulator is needed is one where there is only one client. For those situations the cost of using even the optimized synchronous regulator device infrastructure is not justified, and the `supply-gpios` devicetree property should be used. There is no device interface to these regulators as they are entirely controlled within the driver for the corresponding node, e.g. a sensor.

## API Reference

*group* `regulator_interface`

Regulator Interface.

### Functions

`static inline int regulator_enable(const struct device *reg, struct onoff_client *cli)`

Enable a regulator.

Reference-counted request that a regulator be turned on. This is an asynchronous operation; if successfully initiated the result will be communicated through the `cli` parameter.

A regulator is considered “on” when it has reached a stable/usable state.

---

**Note:** This function is *isr-ok* and *pre-kernel-ok*.

---

#### Parameters

- `reg` – a regulator device
- `cli` – used to notify the caller when the attempt to turn on the regulator has completed.

**Returns** non-negative on successful initiation of the request. Negative values indicate failures from `onoff_request()` or individual regulator drivers.

`static inline int regulator_disable(const struct device *reg)`

Disable a regulator.

Release a regulator after a previous `regulator_enable()` completed successfully.

If the release removes the last dependency on the regulator it will begin a transition to its “off” state. There is currently no mechanism to notify when the regulator has completely turned off.

This must be invoked at most once for each successful `regulator_enable()`.

---

**Note:** This function is *isr-ok*.

---

#### Parameters

- `reg` – a regulator device

**Returns** non-negative on successful completion of the release request. Negative values indicate failures from `onoff_release()` or individual regulator drivers.

`struct regulator_driver_api`

`#include <regulator.h>` Driver-specific API functions to support regulator control.

### 7.21.23 RTC

#### Overview

This is a placeholder for API specific to real-time clocks. Currently all RTC peripherals are implemented through [Counter](#) with device-specific API for counters with real-time support.

#### API Reference

group `rtc_interface`

RTC DS3231 Driver-Specific API.

#### Typedefs

```
typedef void (*maxim_ds3231_alarm_callback_handler_t)(const struct device *dev, uint8_t id,
uint32_t syncclock, void *user_data)
```

Signature for DS3231 alarm callbacks.

The alarm callback is invoked from the system work queue thread. At the point the callback is invoked the corresponding alarm flags will have been cleared from the device status register. The callback is permitted to invoke operations on the device.

**Param dev** the device from which the callback originated

**Param id** the alarm id

**Param syncclock** the value from [maxim\\_ds3231\\_read\\_syncclock\(\)](#) at the time the alarm interrupt was processed.

**Param user\_data** the corresponding parameter from [maxim\\_ds3231\\_alarm::user\\_data](#).

```
typedef void (*maxim_ds3231_notify_callback)(const struct device *dev, struct sys\_notify
*notify, int res)
```

Signature used to notify a user of the DS3231 that an asynchronous operation has completed.

Functions compatible with this type are subject to all the constraints of [sys\\_notify\\_generic\\_callback](#).

**Param dev** the DS3231 device pointer

**Param notify** the notification structure provided in the call

**Param res** the result of the operation.

#### Functions

```
static inline uint32_t maxim_ds3231_read_syncclock(const struct device *dev)
```

Read the local synchronization clock.

Synchronization aligns the DS3231 real-time clock with a stable monotonic local clock which should have a frequency between 1 kHz and 1 MHz and be itself synchronized with the primary system time clock. The accuracy of the alignment and the maximum time between synchronization updates is affected by the resolution of this clock.

On some systems the hardware clock from `k_cycles_get_32()` is suitable, but on others that clock advances too quickly. The frequency of the target-specific clock is provided by [maxim\\_ds3231\\_syncclock\\_frequency\(\)](#).

At this time the value is captured from `k_uptime_get_32()`; future kernel extensions may make a higher-resolution clock available.

---

**Note:** This function is *isr-ok*.

---

#### Parameters

- `dev` – the DS3231 device pointer

**Returns** the current value of the synchronization clock.

```
static inline uint32_t maxim_ds3231_syncclock_frequency(const struct device *dev)
```

Get the frequency of the synchronization clock.

Provides the frequency of the clock used in `maxim_ds3231_read_syncclock()`.

#### Parameters

- `dev` – the DS3231 device pointer

**Returns** the frequency of the selected synchronization clock.

```
int maxim_ds3231_ctrl_update(const struct device *dev, uint8_t set_bits, uint8_t clear_bits)
```

Set and clear specific bits in the control register.

---

**Note:** This function assumes the device register cache is valid. It will not read the register value, and it will write to the device only if the value changes as a result of applying the set and clear changes.

---

---

**Note:** Unlike `maxim_ds3231_stat_update()` the return value from this function indicates the register value after changes were made. That return value is cached for use in subsequent operations.

---

---

**Note:** This function is *supervisor*.

---

**Returns** the non-negative updated value of the register, or a negative error code from an I2C transaction.

```
int maxim_ds3231_stat_update(const struct device *dev, uint8_t set_bits, uint8_t clear_bits)
```

Read the `ctrl_stat` register then set and clear bits in it.

The content of the `ctrl_stat` register will be read, then the set and clear bits applied and the result written back to the device (regardless of whether there appears to be a change in value).

OSF, A1F, and A2F will be written with 1s if the corresponding bits do not appear in either `set_bits` or `clear_bits`. This ensures that if any flag becomes set between the read and the write that indicator will not be cleared.

---

**Note:** Unlike `maxim_ds3231_ctrl_update()` the return value from this function indicates the register value before any changes were made.

---

---

**Note:** This function is *supervisor*.

---

**Parameters**

- `dev` – the DS3231 device pointer
- `set_bits` – bits to be set when writing back. Setting bits other than `MAXIM_DS3231_REG_STAT_EN32kHz` will have no effect.
- `clear_bits` – bits to be cleared when writing back. Include the bits for the status flags you want to clear.

**Returns** the non-negative register value as originally read (disregarding the effect of clears and sets), or a negative error code from an I2C transaction.

```
int maxim_ds3231_get_alarm(const struct device *dev, uint8_t id, struct maxim\_ds3231\_alarm *cfg)
```

Read a DS3231 alarm configuration.

The alarm configuration data is read from the device and reconstructed into the output parameter.

---

**Note:** This function is *supervisor*.

---

**Parameters**

- `dev` – the DS3231 device pointer.
- `id` – the alarm index, which must be 0 (for the 1 s resolution alarm) or 1 (for the 1 min resolution alarm).
- `cfg` – a pointer to a structure into which the configured alarm data will be stored.

**Returns** a non-negative value indicating successful conversion, or a negative error code from an I2C transaction or invalid parameter.

```
int maxim_ds3231_set_alarm(const struct device *dev, uint8_t id, const struct maxim\_ds3231\_alarm *cfg)
```

Configure a DS3231 alarm.

The alarm configuration is validated and stored into the device.

To cancel an alarm use [counter\\_cancel\\_channel\\_alarm\(\)](#).

---

**Note:** This function is *supervisor*.

---

**Parameters**

- `dev` – the DS3231 device pointer.
- `id` – 0 Analog to counter index. ALARM1 is 0 and has 1 s resolution, ALARM2 is 1 and has 1 minute resolution.
- `cfg` – a pointer to the desired alarm configuration. Both alarms are configured; if only one is to change the application must supply the existing configuration for the other.

**Returns** a non-negative value on success, or a negative error code from an I2C transaction or an invalid parameter.

```
int maxim_ds3231_synchronize(const struct device *dev, struct sys_notify *notify)
```

Synchronize the RTC against the local clock.

The RTC advances one tick per second with no access to sub-second precision. Synchronizing clocks at sub-second resolution requires enabling a 1pps signal then capturing the system clocks in a GPIO callback. This function provides that operation.

Synchronization is performed asynchronously, and may take as long as 1 s to complete; notification of completion is provided through the *notify* parameter.

Applications should use *maxim\_ds3231\_get\_syncpoint()* to retrieve the synchronization data collected by this operation.

---

**Note:** This function is *supervisor*.

---

#### Parameters

- *dev* – the DS3231 device pointer.
- *notify* – pointer to the object used to specify asynchronous function behavior and store completion information.

#### Return values

- *non-negative* – on success
- *-EBUSY* – if a synchronization or set is currently in progress
- *-EINVAL* – if *notify* is not provided
- *-ENOTSUP* – if the required interrupt is not configured

```
int maxim_ds3231_req_syncpoint(const struct device *dev, struct k_poll_signal *signal)
```

Request to update the synchronization point.

This is a variant of *maxim\_ds3231\_synchronize()* for use from user threads.

#### Parameters

- *dev* – the DS3231 device pointer.
- *signal* – pointer to a valid and ready-to-be-signalled *k\_poll\_signal*. May be NULL to request a synchronization point be collected without notifying when it has been updated.

#### Return values

- *non-negative* – on success
- *-EBUSY* – if a synchronization or set is currently in progress
- *-ENOTSUP* – if the required interrupt is not configured

```
int maxim_ds3231_get_syncpoint(const struct device *dev, struct maxim_ds3231_syncpoint *syncpoint)
```

Retrieve the most recent synchronization point.

This function returns the synchronization data last captured using *maxim\_ds3231\_synchronize()*.

#### Parameters

- *dev* – the DS3231 device pointer.
- *syncpoint* – where to store the synchronization data.

#### Return values

- non-negative – on success
- -ENOENT – if no syncpoint has been captured

```
int maxim_ds3231_set(const struct device *dev, const struct maxim_ds3231_syncpoint *syncpoint,  
                    struct sys_notify *notify)
```

Set the RTC to a time consistent with the provided synchronization.

The RTC advances one tick per second with no access to sub-second precision, and setting the clock resets the internal countdown chain. This function implements the magic necessary to set the clock while retaining as much sub-second accuracy as possible. It requires a synchronization point that pairs sub-second resolution civil time with a local synchronization clock captured at the same instant. The set operation may take as long as 1 second to complete; notification of completion is provided through the `notify` parameter.

---

**Note:** This function is *supervisor*.

---

#### Parameters

- `dev` – the DS3231 device pointer.
- `syncpoint` – the structure providing the synchronization point.
- `notify` – pointer to the object used to specify asynchronous function behavior and store completion information.

#### Return values

- non-negative – on success
- -EINVAL – if `syncpoint` or `notify` are null
- -ENOTSUP – if the required interrupt signal is not configured
- -EBUSY – if a synchronization or set is currently in progress

```
int maxim_ds3231_check_alarms(const struct device *dev)
```

Check for and clear flags indicating that an alarm has fired.

Returns a mask indicating alarms that are marked as having fired, and clears from `stat` the flags that it found set. Alarms that have been configured with a callback are not represented in the return value.

This API may be used when a persistent alarm has been programmed.

---

**Note:** This function is *supervisor*.

---

#### Parameters

- `dev` – the DS3231 device pointer.

**Returns** a non-negative value that may have `MAXIM_DS3231_ALARM1` and/or `MAXIM_DS3231_ALARM2` set, or a negative error code.

```
struct maxim_ds3231_alarm
```

`#include <maxim_ds3231.h>` Information defining the alarm configuration.

DS3231 alarms can be set to fire at specific times or at the rollover of minute, hour, day, or day of week.

When an alarm is configured with a handler an interrupt will be generated and the handler called from the system work queue.

When an alarm is configured without a handler, or a persisted alarm is present, alarms can be read using [maxim\\_ds3231\\_check\\_alarms\(\)](#).

## Public Members

`time_t time`

Time specification for an RTC alarm.

Though specified as a UNIX time, the alarm parameters are determined by converting to civil time and interpreting the component hours, minutes, seconds, day-of-week, and day-of-month fields, mediated by the corresponding [flags](#).

The year and month are ignored, but be aware that `gmtime()` determines day-of-week based on calendar date. Decoded alarm times will fall within 1978-01 since 1978-01-01 (first of month) was a Sunday (first of week).

[maxim\\_ds3231\\_alarm\\_callback\\_handler\\_t](#) handler

Handler to be invoked when alarms are signalled.

If this is null the alarm will not be triggered by the INTn/SQW GPIO. This is a “persisted” alarm from its role in using the DS3231 to trigger a wake from deep sleep. The application should use [maxim\\_ds3231\\_check\\_alarms\(\)](#) to determine whether such an alarm has been triggered.

If this is not null the driver will monitor the ISW GPIO for alarm signals and will invoke the handler with a parameter carrying the value returned by [maxim\\_ds3231\\_check\\_alarms\(\)](#). The corresponding status flags will be cleared in the device before the handler is invoked.

The handler will be invoked from the system work queue.

`void *user_data`

User-provided pointer passed to alarm callback.

`uint8_t flags`

Flags controlling configuration of the alarm alarm.

See `MAXIM_DS3231_ALARM_FLAGS_IGNSE` and related constants.

Note that as described the alarm mask fields require that if a unit is not ignored, higher-precision units must also not be ignored. For example, if match on hours is enabled, match on minutes and seconds must also be enabled. Failure to comply with this requirement will cause [maxim\\_ds3231\\_set\\_alarm\(\)](#) to return an error, leaving the alarm configuration unchanged.

`struct maxim_ds3231_syncpoint`

`#include <maxim_ds3231.h>` Register the RTC clock against system clocks.

This captures the same instant in both the RTC time scale and a stable system clock scale, allowing conversion between those scales.

## Public Members

`struct timespec rtc`

Time from the DS3231.

This maybe in UTC, TAI, or local offset depending on how the RTC is maintained.

uint32\_t syncclock

Value of a local clock at the same instant as [rtc](#).

This is captured from a stable monotonic system clock running at between 1 kHz and 1 MHz, allowing for microsecond to millisecond accuracy in synchronization.

## 7.21.24 Sensors

The sensor subsystem exposes an API to uniformly access sensor devices. Common operations are: reading data and executing code when specific conditions are met.

### Basic Operation

**Channels** Fundamentally, a channel is a quantity that a sensor device can measure.

Sensors can have multiple channels, either to represent different axes of the same physical property (e.g. acceleration); or because they can measure different properties altogether (ambient temperature, pressure and humidity). Complex sensors cover both cases, so a single device can expose three acceleration channels and a temperature one.

It is imperative that all sensors that support a given channel express results in the same unit of measurement. Consult the [API Reference](#) for all supported channels, along with their description and units of measurement:

**Values** Sensor devices return results as [sensor\\_value](#). This representation avoids use of floating point values as they may not be supported on certain setups.

**Fetching Values** Getting a reading from a sensor requires two operations. First, an application instructs the driver to fetch a sample of all its channels. Then, individual channels may be read. In the case of channels with multiple axes, they can be read in a single operation by supplying the corresponding `_XYZ` channel type and a buffer of 3 [sensor\\_value](#) objects. This approach ensures consistency of channels between reads and efficiency of communication by issuing a single transaction on the underlying bus.

Below is an example illustrating the usage of the BME280 sensor, which measures ambient temperature and atmospheric pressure. Note that [sensor\\_sample\\_fetch\(\)](#) is only called once, as it reads and compensates data for both channels.

```
1  /*
2  *
3  * Get a device structure from a devicetree node with compatible
4  * "bosch,bme280". (If there are multiple, just pick one.)
5  */
6  static const struct device *get_bme280_device(void)
7  {
8      const struct device *dev = DEVICE_DT_GET_ANY(bosch_bme280);
9
10     if (dev == NULL) {
11         /* No such node, or the node does not have status "okay". */
12         printk("\nError: no device found.\n");
13         return NULL;
14     }
15
16     if (!device_is_ready(dev)) {
17         printk("\nError: Device \"%s\" is not ready; "
18             "check the driver initialization logs for errors.\n",
```

(continues on next page)

(continued from previous page)

```

19         dev->name);
20         return NULL;
21     }
22
23     printk("Found device \"%s\", getting sensor data\n", dev->name);
24     return dev;
25 }
26
27 void main(void)
28 {
29     const struct device *dev = get_bme280_device();
30
31     if (dev == NULL) {
32         return;
33     }
34
35     while (1) {
36         struct sensor_value temp, press, humidity;
37
38         sensor_sample_fetch(dev);
39         sensor_channel_get(dev, SENSOR_CHAN_AMBIENT_TEMP, &temp);
40         sensor_channel_get(dev, SENSOR_CHAN_PRESS, &press);
41         sensor_channel_get(dev, SENSOR_CHAN_HUMIDITY, &humidity);
42
43         printk("temp: %d.%06d; press: %d.%06d; humidity: %d.%06d\n",
44             temp.val1, temp.val2, press.val1, press.val2,
45             humidity.val1, humidity.val2);
46
47         k_sleep(K_MSEC(1000));
48     }
49 }

```

The example assumes that the returned values have type `sensor_value`, which is the case for BME280. A real application supporting multiple sensors should inspect the type field of the temp and press values and use the other fields of the structure accordingly.

## Configuration and Attributes

Setting the communication bus and address is considered the most basic configuration for sensor devices. This setting is done at compile time, via the configuration menu. If the sensor supports interrupts, the interrupt lines and triggering parameters described below are also configured at compile time.

Alongside these communication parameters, sensor chips typically expose multiple parameters that control the accuracy and frequency of measurement. In compliance with Zephyr's design goals, most of these values are statically configured at compile time.

However, certain parameters could require runtime configuration, for example, threshold values for interrupts. These values are configured via attributes. The example in the following section showcases a sensor with an interrupt line that is triggered when the temperature crosses a threshold. The threshold is configured at runtime using an attribute.

## Triggers

*Triggers* in Zephyr refer to the interrupt lines of the sensor chips. Many sensor chips support one or more triggers. Some examples of triggers include: new data is ready for reading, a channel value has crossed a threshold, or the device has sensed motion.

To configure a trigger, an application needs to supply a `sensor_trigger` and a handler function. The structure contains the trigger type and the channel on which the trigger must be configured.

Because most sensors are connected via SPI or I2C busses, it is not possible to communicate with them from the interrupt execution context. The execution of the trigger handler is deferred to a thread, so that data fetching operations are possible. A driver can spawn its own thread to fetch data, thus ensuring minimum latency. Alternatively, multiple sensor drivers can share a system-wide thread. The shared thread approach increases the latency of handling interrupts but uses less memory. You can configure which approach to follow for each driver. Most drivers can entirely disable triggers resulting in a smaller footprint.

The following example contains a trigger fired whenever temperature crosses the 26 degree Celsius threshold. It also samples the temperature every second. A real application would ideally disable periodic sampling in the interest of saving power. Since the application has direct access to the kernel config symbols, no trigger is registered when triggering was disabled by the driver's configuration.

133
134         rc = sensor_channel_get(dev, SENSOR_CHAN_AMBIENT_TEMP, &temp);
135         if (rc != 0) {
136             printf("sensor_channel_get error: %d\n", rc);
137             break;
138         }
139
140         printf("%s: %g C\n", now_str(),
141             sensor_value_to_double(&temp));
142
143         k_sleep(K_SECONDS(2));
144     }
145 }

```

## API Reference

*group* sensor\_interface

Sensor Interface.

### Defines

**SENSOR\_G**

The value of gravitational constant in micro  $\text{m/s}^2$ .

**SENSOR\_PI**

The value of constant PI in micros.

**Typedefs**

```
typedef void (*sensor_trigger_handler_t)(const struct device *dev, struct sensor_trigger *trigger)
```

Callback API upon firing of a trigger.

**Param dev** Pointer to the sensor device

**Param trigger** The trigger

```
typedef int (*sensor_attr_set_t)(const struct device *dev, enum sensor_channel chan, enum sensor_attribute attr, const struct sensor_value *val)
```

Callback API upon setting a sensor's attributes.

See *sensor\_attr\_set()* for argument description

```
typedef int (*sensor_attr_get_t)(const struct device *dev, enum sensor_channel chan, enum sensor_attribute attr, struct sensor_value *val)
```

Callback API upon getting a sensor's attributes.

See *sensor\_attr\_get()* for argument description

```
typedef int (*sensor_trigger_set_t)(const struct device *dev, const struct sensor_trigger *trig, sensor_trigger_handler_t handler)
```

Callback API for setting a sensor's trigger and handler.

See *sensor\_trigger\_set()* for argument description

```
typedef int (*sensor_sample_fetch_t)(const struct device *dev, enum sensor_channel chan)
```

Callback API for fetching data from a sensor.

See *sensor\_sample\_fetch()* for argument description

```
typedef int (*sensor_channel_get_t)(const struct device *dev, enum sensor_channel chan, struct sensor_value *val)
```

Callback API for getting a reading from a sensor.

See *sensor\_channel\_get()* for argument description

**Enums**

```
enum sensor_channel
```

Sensor channels.

*Values:*

enumerator *SENSOR\_CHAN\_ACCEL\_X*

Acceleration on the X axis, in  $\text{m/s}^2$ .

enumerator `SENSOR_CHAN_ACCEL_Y`

Acceleration on the Y axis, in  $\text{m/s}^2$ .

enumerator `SENSOR_CHAN_ACCEL_Z`

Acceleration on the Z axis, in  $\text{m/s}^2$ .

enumerator `SENSOR_CHAN_ACCEL_XYZ`

Acceleration on the X, Y and Z axes.

enumerator `SENSOR_CHAN_GYRO_X`

Angular velocity around the X axis, in radians/s.

enumerator `SENSOR_CHAN_GYRO_Y`

Angular velocity around the Y axis, in radians/s.

enumerator `SENSOR_CHAN_GYRO_Z`

Angular velocity around the Z axis, in radians/s.

enumerator `SENSOR_CHAN_GYRO_XYZ`

Angular velocity around the X, Y and Z axes.

enumerator `SENSOR_CHAN_MAGN_X`

Magnetic field on the X axis, in Gauss.

enumerator `SENSOR_CHAN_MAGN_Y`

Magnetic field on the Y axis, in Gauss.

enumerator `SENSOR_CHAN_MAGN_Z`

Magnetic field on the Z axis, in Gauss.

enumerator `SENSOR_CHAN_MAGN_XYZ`

Magnetic field on the X, Y and Z axes.

enumerator `SENSOR_CHAN_DIE_TEMP`

Device die temperature in degrees Celsius.

enumerator `SENSOR_CHAN_AMBIENT_TEMP`

Ambient temperature in degrees Celsius.

enumerator `SENSOR_CHAN_PRESS`

Pressure in kilopascal.

enumerator `SENSOR_CHAN_PROX`

Proximity. Adimensional. A value of 1 indicates that an object is close.

enumerator `SENSOR_CHAN_HUMIDITY`

Humidity, in percent.

enumerator `SENSOR_CHAN_LIGHT`  
Illuminance in visible spectrum, in lux.

enumerator `SENSOR_CHAN_IR`  
Illuminance in infra-red spectrum, in lux.

enumerator `SENSOR_CHAN_RED`  
Illuminance in red spectrum, in lux.

enumerator `SENSOR_CHAN_GREEN`  
Illuminance in green spectrum, in lux.

enumerator `SENSOR_CHAN_BLUE`  
Illuminance in blue spectrum, in lux.

enumerator `SENSOR_CHAN_ALTITUDE`  
Altitude, in meters

enumerator `SENSOR_CHAN_PM_1_0`  
1.0 micro-meters Particulate Matter, in  $\text{ug}/\text{m}^3$

enumerator `SENSOR_CHAN_PM_2_5`  
2.5 micro-meters Particulate Matter, in  $\text{ug}/\text{m}^3$

enumerator `SENSOR_CHAN_PM_10`  
10 micro-meters Particulate Matter, in  $\text{ug}/\text{m}^3$

enumerator `SENSOR_CHAN_DISTANCE`  
Distance. From sensor to target, in meters

enumerator `SENSOR_CHAN_CO2`  
CO2 level, in parts per million (ppm)

enumerator `SENSOR_CHAN_VOC`  
VOC level, in parts per billion (ppb)

enumerator `SENSOR_CHAN_GAS_RES`  
Gas sensor resistance in ohms.

enumerator `SENSOR_CHAN_VOLTAGE`  
Voltage, in volts

enumerator `SENSOR_CHAN_CURRENT`  
Current, in amps

enumerator `SENSOR_CHAN_POWER`  
Power in watts

enumerator SENSOR\_CHAN\_RESISTANCE

Resistance , in Ohm

enumerator SENSOR\_CHAN\_ROTATION

Angular rotation, in degrees

enumerator SENSOR\_CHAN\_POS\_DX

Position change on the X axis, in points.

enumerator SENSOR\_CHAN\_POS\_DY

Position change on the Y axis, in points.

enumerator SENSOR\_CHAN\_POS\_DZ

Position change on the Z axis, in points.

enumerator SENSOR\_CHAN\_RPM

Revolutions per minute, in RPM.

enumerator SENSOR\_CHAN\_GAUGE\_VOLTAGE

Voltage, in volts

enumerator SENSOR\_CHAN\_GAUGE\_AVG\_CURRENT

Average current, in amps

enumerator SENSOR\_CHAN\_GAUGE\_STDBY\_CURRENT

Standby current, in amps

enumerator SENSOR\_CHAN\_GAUGE\_MAX\_LOAD\_CURRENT

Max load current, in amps

enumerator SENSOR\_CHAN\_GAUGE\_TEMP

Gauge temperature

enumerator SENSOR\_CHAN\_GAUGE\_STATE\_OF\_CHARGE

State of charge measurement in %

enumerator SENSOR\_CHAN\_GAUGE\_FULL\_CHARGE\_CAPACITY

Full Charge Capacity in mAh

enumerator SENSOR\_CHAN\_GAUGE\_REMAINING\_CHARGE\_CAPACITY

Remaining Charge Capacity in mAh

enumerator SENSOR\_CHAN\_GAUGE\_NOM\_AVAIL\_CAPACITY

Nominal Available Capacity in mAh

enumerator SENSOR\_CHAN\_GAUGE\_FULL\_AVAIL\_CAPACITY

Full Available Capacity in mAh

enumerator `SENSOR_CHAN_GAUGE_AVG_POWER`

Average power in mW

enumerator `SENSOR_CHAN_GAUGE_STATE_OF_HEALTH`

State of health measurement in %

enumerator `SENSOR_CHAN_GAUGE_TIME_TO_EMPTY`

Time to empty in minutes

enumerator `SENSOR_CHAN_GAUGE_TIME_TO_FULL`

Time to full in minutes

enumerator `SENSOR_CHAN_GAUGE_CYCLE_COUNT`

Cycle count (total number of charge/discharge cycles)

enumerator `SENSOR_CHAN_GAUGE_DESIGN_VOLTAGE`

Design voltage of cell in V (max voltage)

enumerator `SENSOR_CHAN_GAUGE_DESIRED_VOLTAGE`

Desired voltage of cell in V (nominal voltage)

enumerator `SENSOR_CHAN_GAUGE_DESIRED_CHARGING_CURRENT`

Desired charging current in mA

enumerator `SENSOR_CHAN_ALL`

All channels.

enumerator `SENSOR_CHAN_COMMON_COUNT`

Number of all common sensor channels.

enumerator `SENSOR_CHAN_PRIV_START` = [\*SENSOR\\_CHAN\\_COMMON\\_COUNT\*](#)

This and higher values are sensor specific. Refer to the sensor header file.

enumerator `SENSOR_CHAN_MAX` = `INT16_MAX`

Maximum value describing a sensor channel type.

enum `sensor_trigger_type`

Sensor trigger types.

*Values:*

enumerator `SENSOR_TRIG_TIMER`

Timer-based trigger, useful when the sensor does not have an interrupt line.

enumerator `SENSOR_TRIG_DATA_READY`

Trigger fires whenever new data is ready.

enumerator `SENSOR_TRIG_DELTA`

Trigger fires when the selected channel varies significantly. This includes any-motion detection when the channel is acceleration or gyro. If detection is based on slope between successive channel readings, the slope threshold is configured via the [SENSOR\\_ATTR\\_SLOPE\\_TH](#) and [SENSOR\\_ATTR\\_SLOPE\\_DUR](#) attributes.

enumerator `SENSOR_TRIG_NEAR_FAR`

Trigger fires when a near/far event is detected.

enumerator `SENSOR_TRIG_THRESHOLD`

Trigger fires when channel reading transitions configured thresholds. The thresholds are configured via the [SENSOR\\_ATTR\\_LOWER\\_THRESH](#), [SENSOR\\_ATTR\\_UPPER\\_THRESH](#), and [SENSOR\\_ATTR\\_HYSTERESIS](#) attributes.

enumerator `SENSOR_TRIG_TAP`

Trigger fires when a single tap is detected.

enumerator `SENSOR_TRIG_DOUBLE_TAP`

Trigger fires when a double tap is detected.

enumerator `SENSOR_TRIG_FREEFALL`

Trigger fires when a free fall is detected.

enumerator `SENSOR_TRIG_COMMON_COUNT`

Number of all common sensor triggers.

enumerator `SENSOR_TRIG_PRIV_START` = [SENSOR\\_TRIG\\_COMMON\\_COUNT](#)

This and higher values are sensor specific. Refer to the sensor header file.

enumerator `SENSOR_TRIG_MAX` = `INT16_MAX`

Maximum value describing a sensor trigger type.

enum `sensor_attribute`

Sensor attribute types.

*Values:*

enumerator `SENSOR_ATTR_SAMPLING_FREQUENCY`

Sensor sampling frequency, i.e. how many times a second the sensor takes a measurement.

enumerator `SENSOR_ATTR_LOWER_THRESH`

Lower threshold for trigger.

enumerator `SENSOR_ATTR_UPPER_THRESH`

Upper threshold for trigger.

enumerator `SENSOR_ATTR_SLOPE_TH`

Threshold for any-motion (slope) trigger.

enumerator `SENSOR_ATTR_SLOPE_DUR`

Duration for which the slope values needs to be outside the threshold for the trigger to fire.

enumerator `SENSOR_ATTR_HYSTERESIS`

enumerator `SENSOR_ATTR_OVERSAMPLING`

Oversampling factor

enumerator `SENSOR_ATTR_FULL_SCALE`

Sensor range, in SI units.

enumerator `SENSOR_ATTR_OFFSET`

The sensor value returned will be altered by the amount indicated by offset: `final_value = sensor_value + offset`.

enumerator `SENSOR_ATTR_CALIB_TARGET`

Calibration target. This will be used by the internal chip's algorithms to calibrate itself on a certain axis, or all of them.

enumerator `SENSOR_ATTR_CONFIGURATION`

Configure the operating modes of a sensor.

enumerator `SENSOR_ATTR_CALIBRATION`

Set a calibration value needed by a sensor.

enumerator `SENSOR_ATTR_FEATURE_MASK`

Enable/disable sensor features

enumerator `SENSOR_ATTR_ALERT`

Alert threshold or alert enable/disable

enumerator `SENSOR_ATTR_COMMON_COUNT`

Number of all common sensor attributes.

enumerator `SENSOR_ATTR_PRIV_START = SENSOR_ATTR_COMMON_COUNT`

This and higher values are sensor specific. Refer to the sensor header file.

enumerator `SENSOR_ATTR_MAX = INT16_MAX`

Maximum value describing a sensor attribute type.

## Functions

```
int sensor_attr_set(const struct device *dev, enum sensor_channel chan, enum sensor_attribute attr, const struct sensor_value *val)
```

Set an attribute for a sensor.

### Parameters

- `dev` – Pointer to the sensor device

- `chan` – The channel the attribute belongs to, if any. Some attributes may only be set for all channels of a device, depending on device capabilities.
- `attr` – The attribute to set
- `val` – The value to set the attribute to

**Returns** 0 if successful, negative `errno` code if failure.

```
int sensor_attr_get(const struct device *dev, enum sensor\_channel chan, enum sensor\_attribute attr, struct sensor\_value *val)
```

Get an attribute for a sensor.

#### Parameters

- `dev` – Pointer to the sensor device
- `chan` – The channel the attribute belongs to, if any. Some attributes may only be set for all channels of a device, depending on device capabilities.
- `attr` – The attribute to get
- `val` – Pointer to where to store the attribute

**Returns** 0 if successful, negative `errno` code if failure.

```
static inline int sensor_trigger_set(const struct device *dev, struct sensor\_trigger *trig, sensor\_trigger\_handler\_t handler)
```

Activate a sensor's trigger and set the trigger handler.

The handler will be called from a thread, so I2C or SPI operations are safe. However, the thread's stack is limited and defined by the driver. It is currently up to the caller to ensure that the handler does not overflow the stack.

### Function properties (list may not be complete) [supervisor](#)

#### Parameters

- `dev` – Pointer to the sensor device
- `trig` – The trigger to activate
- `handler` – The function that should be called when the trigger fires

**Returns** 0 if successful, negative `errno` code if failure.

```
int sensor_sample_fetch(const struct device *dev)
```

Fetch a sample from the sensor and store it in an internal driver buffer.

Read all of a sensor's active channels and, if necessary, perform any additional operations necessary to make the values useful. The user may then get individual channel values by calling [sensor\\_channel\\_get](#).

Since the function communicates with the sensor device, it is unsafe to call it in an ISR if the device is connected via I2C or SPI.

#### Parameters

- `dev` – Pointer to the sensor device

**Returns** 0 if successful, negative `errno` code if failure.

```
int sensor_sample_fetch_chan(const struct device *dev, enum sensor\_channel type)
```

Fetch a sample from the sensor and store it in an internal driver buffer.

Read and compute compensation for one type of sensor data (magnetometer, accelerometer, etc). The user may then get individual channel values by calling [sensor\\_channel\\_get](#).

This is mostly implemented by multi function devices enabling reading at different sampling rates.

Since the function communicates with the sensor device, it is unsafe to call it in an ISR if the device is connected via I2C or SPI.

**Parameters**

- `dev` – Pointer to the sensor device
- `type` – The channel that needs updated

**Returns** 0 if successful, negative `errno` code if failure.

```
int sensor_channel_get(const struct device *dev, enum sensor\_channel chan, struct sensor\_value *val)
```

Get a reading from a sensor device.

Return a useful value for a particular channel, from the driver's internal data. Before calling this function, a sample must be obtained by calling [sensor\\_sample\\_fetch](#) or [sensor\\_sample\\_fetch\\_chan](#). It is guaranteed that two subsequent calls of this function for the same channels will yield the same value, if [sensor\\_sample\\_fetch](#) or [sensor\\_sample\\_fetch\\_chan](#) has not been called in the meantime.

For vectorial data samples you can request all axes in just one call by passing the specific channel with `_XYZ` suffix. The sample will be returned at `val[0]`, `val[1]` and `val[2]` (X, Y and Z in that order).

**Parameters**

- `dev` – Pointer to the sensor device
- `chan` – The channel to read
- `val` – Where to store the value

**Returns** 0 if successful, negative `errno` code if failure.

```
static inline int32_t sensor_ms2_to_g(const struct sensor\_value *ms2)
```

Helper function to convert acceleration from  $\text{m/s}^2$  to Gs.

**Parameters**

- `ms2` – A pointer to a [sensor\\_value](#) struct holding the acceleration, in  $\text{m/s}^2$ .

**Returns** The converted value, in Gs.

```
static inline void sensor_g_to_ms2(int32_t g, struct sensor\_value *ms2)
```

Helper function to convert acceleration from Gs to  $\text{m/s}^2$ .

**Parameters**

- `g` – The G value to be converted.
- `ms2` – A pointer to a [sensor\\_value](#) struct, where the result is stored.

```
static inline int32_t sensor_rad_to_degrees(const struct sensor\_value *rad)
```

Helper function for converting radians to degrees.

**Parameters**

- `rad` – A pointer to a [sensor\\_value](#) struct, holding the value in radians.

**Returns** The converted value, in degrees.

```
static inline void sensor_degrees_to_rad(int32_t d, struct sensor\_value *rad)
```

Helper function for converting degrees to radians.

**Parameters**

- `d` – The value (in degrees) to be converted.

- `rad` – A pointer to a `sensor_value` struct, where the result is stored.

static inline double `sensor_value_to_double`(const struct `sensor_value` \*`val`)

Helper function for converting struct `sensor_value` to double.

#### Parameters

- `val` – A pointer to a `sensor_value` struct.

**Returns** The converted value.

static inline void `sensor_value_from_double`(struct `sensor_value` \*`val`, double `inp`)

Helper function for converting double to struct `sensor_value`.

#### Parameters

- `val` – A pointer to a `sensor_value` struct.
- `inp` – The converted value.

struct `sensor_value`

*#include <sensor.h>* Representation of a sensor readout value.

The value is represented as having an integer and a fractional part, and can be obtained using the formula `val1 + val2 * 10-6`. Negative values also adhere to the above formula, but may need special attention. Here are some examples of the value representation:

```
0.5: val1 = 0, val2 = 500000
-0.5: val1 = 0, val2 = -500000
-1.0: val1 = -1, val2 = 0
-1.5: val1 = -1, val2 = -500000
```

#### Public Members

int32\_t `val1`

Integer part of the value.

int32\_t `val2`

Fractional part of the value (in one-millionth parts).

struct `sensor_trigger`

*#include <sensor.h>* Sensor trigger spec.

#### Public Members

enum `sensor_trigger_type` `type`

Trigger type.

enum `sensor_channel` `chan`

Channel the trigger is set on.

struct `sensor_driver_api`

*#include <sensor.h>*

## 7.21.25 SPI

### Overview

### API Reference

*group* spi\_interface

SPI Interface.

#### Defines

SPI\_OP\_MODE\_MASTER

SPI operational mode.

SPI\_OP\_MODE\_SLAVE

SPI\_OP\_MODE\_MASK

SPI\_OP\_MODE\_GET(\_operation\_)

SPI\_MODE\_CPOL

SPI Polarity & Phase Modes.

Clock Polarity: if set, clock idle state will be 1 and active state will be 0. If untouched, the inverse will be true which is the default.

SPI\_MODE\_CPHA

Clock Phase: this dictates when is the data captured, and depends clock's polarity. When SPI\_MODE\_CPOL is set and this bit as well, capture will occur on low to high transition and high to low if this bit is not set (default). This is fully reversed if CPOL is not set.

SPI\_MODE\_LOOP

Whatever data is transmitted is looped-back to the receiving buffer of the controller. This is fully controller dependent as some may not support this, and can be used for testing purposes only.

SPI\_MODE\_MASK

SPI\_MODE\_GET(\_mode\_)

SPI\_TRANSFER\_MSB

SPI Transfer modes (host controller dependent)

SPI\_TRANSFER\_LSB

SPI\_WORD\_SIZE\_SHIFT

SPI word size.

SPI\_WORD\_SIZE\_MASK

`SPI_WORD_SIZE_GET(_operation_)`

`SPI_WORD_SET(_word_size_)`

`SPI_LINES_SINGLE`

SPI MISO lines.

Some controllers support dual, quad or octal MISO lines connected to slaves. Default is single, which is the case most of the time.

`SPI_LINES_DUAL`

`SPI_LINES_QUAD`

`SPI_LINES_OCTAL`

`SPI_LINES_MASK`

`SPI_HOLD_ON_CS`

Specific SPI devices control bits.

`SPI_LOCK_ON`

`SPI_CS_ACTIVE_HIGH`

`SPI_CS_CONTROL_PTR_DT(node_id, delay_)`

Initialize and get a pointer to a `spi_cs_control` from a devicetree node identifier.

This helper is useful for initializing a device on a SPI bus. It initializes a struct `spi_cs_control` and returns a pointer to it. Here, `node_id` is a node identifier for a SPI device, not a SPI controller.

Example devicetree fragment:

```
spi@... {
    cs-gpios = <&gpio0 1 GPIO_ACTIVE_LOW>;
    spidev: spi-device@0 { ... };
};
```

Assume that `gpio0` follows the standard convention for specifying GPIOs, i.e. it has the following in its binding:

```
gpio-cells:
- pin
- flags
```

Example usage:

```
struct spi_cs_control *ctrl =
    SPI_CS_CONTROL_PTR_DT(DT_NODELABEL(spidev), 2);
```

This example is equivalent to:

```
struct spi_cs_control *ctrl =
    &(struct spi_cs_control) {
        .gpio_dev = DEVICE_DT_GET(DT_NODELABEL(gpio0)),
```

(continues on next page)

(continued from previous page)

```

        .delay = 2,
        .gpio_pin = 1,
        .gpio_dt_flags = GPIO_ACTIVE_LOW
    };

```

This macro is not available in C++.

#### Parameters

- `node_id` – Devicetree node identifier for a device on a SPI bus
- `delay_` – The delay field to set in the `spi_cs_control`

**Returns** a pointer to the `spi_cs_control` structure

`SPI_CS_CONTROL_PTR_DT_INST(inst, delay_)`

Get a pointer to a `spi_cs_control` from a devicetree node.

This is equivalent to `SPI_CS_CONTROL_PTR_DT(DT_DRV_INST(inst), delay_)`.

Therefore, `DT_DRV_COMPAT` must already be defined before using this macro.

This macro is not available in C++.

#### Parameters

- `inst` – Devicetree node instance number
- `delay_` – The delay field to set in the `spi_cs_control`

**Returns** a pointer to the `spi_cs_control` structure

`SPI_CONFIG_DT(node_id, operation_, delay_)`

Structure initializer for `spi_config` from devicetree.

This helper macro expands to a static initializer for a struct `spi_config` by reading the relevant frequency, slave, and cs data from the devicetree.

Important: the `cs` field is initialized using `SPI_CS_CONTROL_PTR_DT()`. The `gpio_dev` value pointed to by this structure must be checked using `device_is_ready()` before use.

This macro is not available in C++.

#### Parameters

- `node_id` – Devicetree node identifier for the SPI device whose struct `spi_config` to create an initializer for
- `operation_` – the desired operation field in the struct `spi_config`
- `delay_` – the desired delay field in the struct `spi_config`'s `spi_cs_control`, if there is one

`SPI_CONFIG_DT_INST(inst, operation_, delay_)`

Structure initializer for `spi_config` from devicetree instance.

This is equivalent to `SPI_CONFIG_DT(DT_DRV_INST(inst), operation_, delay_)`.

This macro is not available in C++.

#### Parameters

- `inst` – Devicetree instance number
- `operation_` – the desired operation field in the struct `spi_config`
- `delay_` – the desired delay field in the struct `spi_config`'s `spi_cs_control`, if there is one

`SPI_DT_SPEC_GET(node_id, operation_, delay_)`

Structure initializer for `spi_dt_spec` from devicetree.

This helper macro expands to a static initializer for a struct `spi_dt_spec` by reading the relevant bus, frequency, slave, and cs data from the devicetree.

Important: multiple fields are automatically constructed by this macro which must be checked before use. `spi_is_ready` performs the required `device_is_ready` checks.

This macro is not available in C++.

#### Parameters

- `node_id` – Devicetree node identifier for the SPI device whose struct `spi_dt_spec` to create an initializer for
- `operation_` – the desired operation field in the struct `spi_config`
- `delay_` – the desired delay field in the struct `spi_config`'s `spi_cs_control`, if there is one

`SPI_DT_SPEC_INST_GET(inst, operation_, delay_)`

Structure initializer for `spi_dt_spec` from devicetree instance.

This is equivalent to `SPI_DT_SPEC_GET(DT_DRV_INST(inst), operation_, delay_)`.

This macro is not available in C++.

#### Parameters

- `inst` – Devicetree instance number
- `operation_` – the desired operation field in the struct `spi_config`
- `delay_` – the desired delay field in the struct `spi_config`'s `spi_cs_control`, if there is one

## Typedefs

```
typedef int (*spi_api_io)(const struct device *dev, const struct spi_config *config, const struct spi_buf_set *tx_bufs, const struct spi_buf_set *rx_bufs)
```

Callback API for I/O See `spi_transceive()` for argument descriptions.

Callback API for asynchronous I/O See `spi_transceive_async()` for argument descriptions.

```
typedef int (*spi_api_io_async)(const struct device *dev, const struct spi_config *config, const struct spi_buf_set *tx_bufs, const struct spi_buf_set *rx_bufs, struct k_poll_signal *async)
```

```
typedef int (*spi_api_release)(const struct device *dev, const struct spi_config *config)
```

Callback API for unlocking SPI device. See `spi_release()` for argument descriptions.

## Functions

```
static inline bool spi_is_ready(const struct spi_dt_spec *spec)
```

Validate that SPI bus is ready.

#### Parameters

- `spec` – SPI specification from devicetree

#### Return values

- `true` – if the SPI bus is ready for use.

- `false` – if the SPI bus is not ready for use.

```
int spi_transceive(const struct device *dev, const struct spi_config *config, const struct  
                  spi_buf_set *tx_bufs, const struct spi_buf_set *rx_bufs)
```

Read/write the specified amount of data from the SPI driver.

---

**Note:** This function is synchronous.

---

#### Parameters

- `dev` – Pointer to the device structure for the driver instance
- `config` – Pointer to a valid *spi\_config* structure instance. Pointer-comparison may be used to detect changes from previous operations.
- `tx_bufs` – Buffer array where data to be sent originates from, or NULL if none.
- `rx_bufs` – Buffer array where data to be read will be written to, or NULL if none.

#### Return values

- `frames` – Positive number of frames received in slave mode.
- `0` – If successful in master mode.
- `-errno` – Negative errno code on failure.

```
static inline int spi_transceive_dt(const struct spi_dt_spec *spec, const struct spi_buf_set  
                                   *tx_bufs, const struct spi_buf_set *rx_bufs)
```

Read/write data from an SPI bus specified in *spi\_dt\_spec*.

This is equivalent to:

```
spi_transceive(spec->bus, &spec->config, tx_bufs, rx_bufs);
```

#### Parameters

- `spec` – SPI specification from devicetree
- `tx_bufs` – Buffer array where data to be sent originates from, or NULL if none.
- `rx_bufs` – Buffer array where data to be read will be written to, or NULL if none.

**Returns** a value from *spi\_transceive()*.

```
static inline int spi_read(const struct device *dev, const struct spi_config *config, const struct  
                          spi_buf_set *rx_bufs)
```

Read the specified amount of data from the SPI driver.

---

**Note:** This function is synchronous.

---

---

**Note:** This function is an helper function calling *spi\_transceive*.

---

#### Parameters

- `dev` – Pointer to the device structure for the driver instance

- `config` – Pointer to a valid [spi\\_config](#) structure instance. Pointer-comparison may be used to detect changes from previous operations.
- `rx_bufs` – Buffer array where data to be read will be written to.

**Return values**

- 0 – If successful.
- `-errno` – Negative `errno` code on failure.

static inline int spi\_read\_dt(const struct [spi\\_dt\\_spec](#) \*spec, const struct [spi\\_buf\\_set](#) \*rx\_bufs)  
Read data from a SPI bus specified in [spi\\_dt\\_spec](#).

This is equivalent to:

```
spi_read(spec->bus, &spec->config, rx_bufs);
```

**Parameters**

- `spec` – SPI specification from devicetree
- `rx_bufs` – Buffer array where data to be read will be written to.

**Returns** a value from [spi\\_read\(\)](#).

static inline int spi\_write(const struct [device](#) \*dev, const struct [spi\\_config](#) \*config, const struct [spi\\_buf\\_set](#) \*tx\_bufs)  
Write the specified amount of data from the SPI driver.

---

**Note:** This function is synchronous.

---

---

**Note:** This function is an helper function calling `spi_transceive`.

---

**Parameters**

- `dev` – Pointer to the device structure for the driver instance
- `config` – Pointer to a valid [spi\\_config](#) structure instance. Pointer-comparison may be used to detect changes from previous operations.
- `tx_bufs` – Buffer array where data to be sent originates from.

**Return values**

- 0 – If successful.
- `-errno` – Negative `errno` code on failure.

static inline int spi\_write\_dt(const struct [spi\\_dt\\_spec](#) \*spec, const struct [spi\\_buf\\_set](#) \*tx\_bufs)  
Write data to a SPI bus specified in [spi\\_dt\\_spec](#).

This is equivalent to:

```
spi_write(spec->bus, &spec->config, tx_bufs);
```

**Parameters**

- `spec` – SPI specification from devicetree
- `tx_bufs` – Buffer array where data to be sent originates from.

**Returns** a value from [spi\\_write\(\)](#).

```
static inline int spi_transceive_async(const struct device *dev, const struct spi_config *config,  
                                     const struct spi_buf_set *tx_bufs, const struct spi_buf_set  
                                     *rx_bufs, struct k_poll_signal *async)
```

Read/write the specified amount of data from the SPI driver.

---

**Note:** This function is asynchronous.

---

---

**Note:** This function is available only if **:kconfig: `CONFIG\_SPI\_ASYNC`** is selected.

---

#### Parameters

- *dev* – Pointer to the device structure for the driver instance
- *config* – Pointer to a valid *spi\_config* structure instance. Pointer-comparison may be used to detect changes from previous operations.
- *tx\_bufs* – Buffer array where data to be sent originates from, or NULL if none.
- *rx\_bufs* – Buffer array where data to be read will be written to, or NULL if none.
- *async* – A pointer to a valid and ready to be signaled struct *k\_poll\_signal*. (Note: if NULL this function will not notify the end of the transaction, and whether it went successfully or not).

#### Return values

- *frames* – Positive number of frames received in slave mode.
- 0 – If successful in master mode.
- *-errno* – Negative errno code on failure.

```
static inline int spi_read_async(const struct device *dev, const struct spi_config *config, const  
                                struct spi_buf_set *rx_bufs, struct k_poll_signal *async)
```

Read the specified amount of data from the SPI driver.

---

**Note:** This function is asynchronous.

---

---

**Note:** This function is an helper function calling *spi\_transceive\_async*.

---

---

**Note:** This function is available only if **:kconfig: `CONFIG\_SPI\_ASYNC`** is selected.

---

#### Parameters

- *dev* – Pointer to the device structure for the driver instance
- *config* – Pointer to a valid *spi\_config* structure instance. Pointer-comparison may be used to detect changes from previous operations.
- *rx\_bufs* – Buffer array where data to be read will be written to.
- *async* – A pointer to a valid and ready to be signaled struct *k\_poll\_signal*. (Note: if NULL this function will not notify the end of the transaction, and whether it went successfully or not).

#### Return values

- 0 – If successful
- -errno – Negative errno code on failure.

```
static inline int spi_write_async(const struct device *dev, const struct spi_config *config, const
                                struct spi_buf_set *tx_bufs, struct k_poll_signal *async)
```

Write the specified amount of data from the SPI driver.

---

**Note:** This function is asynchronous.

---

---

**Note:** This function is an helper function calling `spi_transceive_async`.

---

---

**Note:** This function is available only if `:kconfig: `CONFIG_SPI_ASYNC`` is selected.

---

#### Parameters

- `dev` – Pointer to the device structure for the driver instance
- `config` – Pointer to a valid *spi\_config* structure instance. Pointer-comparison may be used to detect changes from previous operations.
- `tx_bufs` – Buffer array where data to be sent originates from.
- `async` – A pointer to a valid and ready to be signaled struct *k\_poll\_signal*. (Note: if NULL this function will not notify the end of the transaction, and whether it went successfully or not).

#### Return values

- 0 – If successful.
- -errno – Negative errno code on failure.

```
int spi_release(const struct device *dev, const struct spi_config *config)
```

Release the SPI device locked on by the current config.

Note: This synchronous function is used to release the lock on the SPI device that was kept if, and if only, given config parameter was the last one to be used (in any of the above functions) and if it has the SPI\_LOCK\_ON bit set into its operation bits field. This can be used if the caller needs to keep its hand on the SPI device for consecutive transactions.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance
- `config` – Pointer to a valid *spi\_config* structure instance. Pointer-comparison may be used to detect changes from previous operations.

#### Return values

- 0 – If successful.
- -errno – Negative errno code on failure.

```
static inline int spi_release_dt(const struct spi_dt_spec *spec)
```

Release the SPI device specified in *spi\_dt\_spec*.

This is equivalent to:

```
spi_release(spec->bus, &spec->config);
```

**Parameters**

- `spec` – SPI specification from devicetree

**Returns** a value from [spi\\_release\(\)](#).

```
struct spi_cs_control
```

`#include <spi.h>` SPI Chip Select control structure.

This can be used to control a CS line via a GPIO line, instead of using the controller inner CS logic.

**Param `gpio_dev`** is a valid pointer to an actual GPIO device. A NULL pointer can be provided to full inhibit CS control if necessary.

**Param `gpio_pin`** is a number representing the gpio PIN that will be used to act as a CS line

**Param `delay`** is a delay in microseconds to wait before starting the transmission and before releasing the CS line

**Param `gpio_dt_flags`** is the devicetree flags corresponding to how the CS line should be driven. `GPIO_ACTIVE_LOW`/`GPIO_ACTIVE_HIGH` should be equivalent to `SPI_CS_ACTIVE_HIGH`/`SPI_CS_ACTIVE_LOW` options in struct [spi\\_config](#).

```
struct spi_config
```

`#include <spi.h>` SPI controller configuration structure.

---

**Note:** Only `cs_hold` and `lock_on` can be changed between consecutive transceive call. Rest of the attributes are not meant to be tweaked.

---

**Warning:** Most drivers use pointer comparison to determine whether a passed configuration is different from one used in a previous transaction. Changes to fields in the structure may not be detected.

**Param `frequency`** is the bus frequency in Hertz

**Param `operation`** is a bit field with the following parts:

operational mode	[ 0 ]	- master or slave.
mode	[ 1 : 3 ]	- Polarity, phase and loop mode.
transfer	[ 4 ]	- LSB or MSB first.
word_size	[ 5 : 10 ]	- Size of a data frame in bits.
lines	[ 11 : 12 ]	- MISO lines: Single/Dual/Quad/ ↪ Octal.
cs_hold	[ 13 ]	- Hold on the CS line if possible.
lock_on	[ 14 ]	- Keep resource locked for the ↪ caller.
cs_active_high	[ 15 ]	- Active high CS logic.

**Param `slave`** is the slave number from 0 to host controller slave limit.

**Param `cs`** is a valid pointer on a struct [spi\\_cs\\_control](#) if CS line is emulated through a gpio line, or NULL otherwise.

```
struct spi_dt_spec
```

`#include <spi.h>` Complete SPI DT information.

**Param bus** is the SPI bus

**Param config** is the slave specific configuration

struct spi\_buf

*#include <spi.h>* SPI buffer structure.

**Param buf** is a valid pointer on a data buffer, or NULL otherwise.

**Param len** is the length of the buffer or, if buf is NULL, will be the length which as to be sent as dummy bytes (as TX buffer) or the length of bytes that should be skipped (as RX buffer).

struct spi\_buf\_set

*#include <spi.h>* SPI buffer array structure.

**Param buffers** is a valid pointer on an array of [spi\\_buf](#), or NULL.

**Param count** is the length of the array pointed by buffers.

struct spi\_driver\_api

*#include <spi.h>* SPI driver API This is the mandatory API any SPI driver needs to expose.

## 7.21.26 UART

### Overview

### API Reference

group uart\_interface

UART Interface.

### Typedefs

typedef void (\*uart\_callback\_t)(const struct [device](#) \*dev, struct [uart\\_event](#) \*evt, void \*user\_data)

Define the application callback function signature for [uart\\_callback\\_set\(\)](#) function.

**Param dev** UART device structure.

**Param evt** Pointer to [uart\\_event](#) structure.

**Param user\_data** Pointer to data specified by user.

typedef void (\*uart\_irq\_callback\_user\_data\_t)(const struct [device](#) \*dev, void \*user\_data)

Define the application callback function signature for [uart\\_irq\\_callback\\_user\\_data\\_set\(\)](#) function.

**Param dev** UART device structure.

**Param user\_data** Arbitrary user data.

typedef void (\*uart\_irq\_config\_func\_t)(const struct [device](#) \*dev)

For configuring IRQ on each individual UART device.

**Param dev** UART device structure.

## Enums

enum uart\_line\_ctrl

Line control signals.

Values:

enumerator UART\_LINE\_CTRL\_BAUD\_RATE = *BIT*(0)

enumerator UART\_LINE\_CTRL\_RTS = *BIT*(1)

enumerator UART\_LINE\_CTRL\_DTR = *BIT*(2)

enumerator UART\_LINE\_CTRL\_DCD = *BIT*(3)

enumerator UART\_LINE\_CTRL\_DSR = *BIT*(4)

enum uart\_event\_type

Types of events passed to callback in UART\_ASYNC\_API.

Receiving:

- a. To start receiving, `uart_rx_enable` has to be called with first buffer
- b. When receiving starts to current buffer, `uart_event_type::UART_RX_BUF_REQUEST` will be generated, in response to that user can either:
  - Provide second buffer using `uart_rx_buf_rsp`, when first buffer is filled, receiving will automatically start to second buffer.
  - Ignore the event, this way when current buffer is filled `uart_event_type::UART_RX_RDY` event will be generated and receiving will be stopped.
- c. If some data was received and timeout occurred `uart_event_type::UART_RX_RDY` event will be generated. It can happen multiples times for the same buffer. RX timeout is counted from last byte received i.e. if no data was received, there won't be any timeout event.
- d. After buffer is filled `uart_event_type::UART_RX_RDY` will be generated, immediately followed by `uart_event_type::UART_RX_BUF_RELEASED` indicating that current buffer is no longer used.
- e. If there was second buffer provided, it will become current buffer and we start again at point 2. If no second buffer was specified receiving is stopped and `uart_event_type::UART_RX_DISABLED` event is generated. After that whole process can be repeated.

Any time during reception `uart_event_type::UART_RX_STOPPED` event can occur. if there is any data received, `uart_event_type::UART_RX_RDY` event will be generated. It will be followed by `uart_event_type::UART_RX_BUF_RELEASED` event for every buffer currently passed to driver and finally by `uart_event_type::UART_RX_DISABLED` event.

Receiving can be disabled using `uart_rx_disable`, after calling that function, if there is any data received, `uart_event_type::UART_RX_RDY` event will be generated. `uart_event_type::UART_RX_BUF_RELEASED` event will be generated for every buffer currently passed to driver and finally `uart_event_type::UART_RX_DISABLED` event will occur.

Transmitting:

- a. Transmitting starts by `uart_tx` function.
- b. If whole buffer was transmitted `uart_event_type::UART_TX_DONE` is generated. If timeout occurred `uart_event_type::UART_TX_ABORTED` will be generated.

Transmitting can be aborted using `uart_tx_abort`, after calling that function `uart_event_type::UART_TX_ABORTED` event will be generated.

Values:

enumerator `UART_TX_DONE`

Whole TX buffer was transmitted.

enumerator `UART_TX_ABORTED`

Transmitting aborted due to timeout or `uart_tx_abort` call.

When flow control is enabled, there is a possibility that TX transfer won't finish in the allotted time. Some data may have been transferred, information about it can be found in event data.

enumerator `UART_RX_RDY`

Received data is ready for processing.

This event is generated in the following cases:

- When RX timeout occurred, and data was stored in provided buffer. This can happen multiple times in the same buffer.
- When provided buffer is full.
- After `uart_rx_disable()`.
- After stopping due to external event (`uart_event_type::UART_RX_STOPPED`).

enumerator `UART_RX_BUF_REQUEST`

Driver requests next buffer for continuous reception.

This event is triggered when receiving has started for a new buffer, i.e. it's time to provide a next buffer for a seamless switchover to it. For continuous reliable receiving, user should provide another RX buffer in response to this event, using `uart_rx_buf_rsp` function

If `uart_rx_buf_rsp` is not called before current buffer is filled up, receiving will stop.

enumerator `UART_RX_BUF_RELEASED`

Buffer is no longer used by UART driver.

enumerator `UART_RX_DISABLED`

RX has been disabled and can be reenabled.

This event is generated whenever receiver has been stopped, disabled or finished its operation and can be enabled again using `uart_rx_enable`

enumerator `UART_RX_STOPPED`

RX has stopped due to external event.

Reason is one of `uart_rx_stop_reason`.

enum `uart_rx_stop_reason`

Reception stop reasons.

Values that correspond to events or errors responsible for stopping receiving.

Values:

enumerator UART\_ERROR\_OVERRUN = (1 << 0)

Overrun error.

enumerator UART\_ERROR\_PARITY = (1 << 1)

Parity error.

enumerator UART\_ERROR\_FRAMING = (1 << 2)

Framing error.

enumerator UART\_BREAK = (1 << 3)

Break interrupt.

A break interrupt was received. This happens when the serial input is held at a logic '0' state for longer than the sum of start time + data bits + parity + stop bits.

enumerator UART\_ERROR\_COLLISION = (1 << 4)

Collision error.

This error is raised when transmitted data does not match received data. Typically this is useful in scenarios where the TX and RX lines maybe connected together such as RS-485 half-duplex. This error is only valid on UARTs that support collision checking.

enum uart\_config\_parity

Parity modes.

*Values:*

enumerator UART\_CFG\_PARITY\_NONE

enumerator UART\_CFG\_PARITY\_ODD

enumerator UART\_CFG\_PARITY\_EVEN

enumerator UART\_CFG\_PARITY\_MARK

enumerator UART\_CFG\_PARITY\_SPACE

enum uart\_config\_stop\_bits

Number of stop bits.

*Values:*

enumerator UART\_CFG\_STOP\_BITS\_0\_5

enumerator UART\_CFG\_STOP\_BITS\_1

enumerator UART\_CFG\_STOP\_BITS\_1\_5

enumerator UART\_CFG\_STOP\_BITS\_2

enum uart\_config\_data\_bits

Number of data bits.

*Values:*

enumerator UART\_CFG\_DATA\_BITS\_5

enumerator UART\_CFG\_DATA\_BITS\_6

enumerator UART\_CFG\_DATA\_BITS\_7

enumerator UART\_CFG\_DATA\_BITS\_8

enumerator UART\_CFG\_DATA\_BITS\_9

enum uart\_config\_flow\_control

Hardware flow control options.

With flow control set to none, any operations related to flow control signals can be managed by user with `uart_line_ctrl` functions. In other cases, flow control is managed by hardware/driver.

*Values:*

enumerator UART\_CFG\_FLOW\_CTRL\_NONE

enumerator UART\_CFG\_FLOW\_CTRL\_RTS\_CTS

enumerator UART\_CFG\_FLOW\_CTRL\_DTR\_DSR

## Functions

static inline int `uart_callback_set`(const struct [device](#) \*dev, [uart\\_callback\\_t](#) callback, void \*user\_data)

Set event handler function.

### Parameters

- `dev` – UART device structure.
- `callback` – Event handler.
- `user_data` – Data to pass to event handler function.

### Return values

- `-ENOTSUP` – If not supported.
- `0` – If successful, negative `errno` code otherwise.

int `uart_tx`(const struct [device](#) \*dev, const uint8\_t \*buf, size\_t len, int32\_t timeout)

Send given number of bytes from buffer through UART.

Function returns immediately and event handler, set using [uart\\_callback\\_set](#), is called after transfer is finished.

### Parameters

- `dev` – UART device structure.
- `buf` – Pointer to transmit buffer.
- `len` – Length of transmit buffer.
- `timeout` – Timeout in milliseconds. Valid only if flow control is enabled. `SYS_FOREVER_MS` disables timeout.

**Return values**

- `-ENOTSUP` – If not supported.
- `-EBUSY` – There is already an ongoing transfer.
- `0` – If successful, negative `errno` code otherwise.

`int uart_tx_abort(const struct device *dev)`

Abort current TX transmission.

`uart_event_type::UART_TX_DONE` event will be generated with amount of data sent.

**Parameters**

- `dev` – UART device structure.

**Return values**

- `-ENOTSUP` – If not supported.
- `-EFAULT` – There is no active transmission.
- `0` – If successful, negative `errno` code otherwise.

`int uart_rx_enable(const struct device *dev, uint8_t *buf, size_t len, int32_t timeout)`

Start receiving data through UART.

Function sets given buffer as first buffer for receiving and returns immediately. After that event handler, set using [uart\\_callback\\_set](#), is called with `uart_event_type::UART_RX_RDY` or `uart_event_type::UART_RX_BUF_REQUEST` events.

**Parameters**

- `dev` – UART device structure.
- `buf` – Pointer to receive buffer.
- `len` – Buffer length.
- `timeout` – Inactivity period after receiving at least a byte which triggers `uart_event_type::UART_RX_RDY` event. Given in milliseconds. `SYS_FOREVER_MS` disables timeout. See [uart\\_event\\_type](#) for details.

**Return values**

- `-ENOTSUP` – If not supported.
- `-EBUSY` – RX already in progress.
- `0` – If successful, negative `errno` code otherwise.

`static inline int uart_rx_buf_rsp(const struct device *dev, uint8_t *buf, size_t len)`

Provide receive buffer in response to `uart_event_type::UART_RX_BUF_REQUEST` event.

Provide pointer to RX buffer, which will be used when current buffer is filled.

---

**Note:** Providing buffer that is already in usage by driver leads to undefined behavior. Buffer can be reused when it has been released by driver.

---

**Parameters**

- dev – UART device structure.
- buf – Pointer to receive buffer.
- len – Buffer length.

**Return values**

- -ENOTSUP – If not supported.
- -EBUSY – Next buffer already set.
- -EACCES – Receiver is already disabled (function called too late?).
- 0 – If successful, negative errno code otherwise.

int uart\_rx\_disable(const struct *device* \*dev)

Disable RX.

*uart\_event\_type::UART\_RX\_BUF\_RELEASED* event will be generated for every buffer scheduled, after that *uart\_event\_type::UART\_RX\_DISABLED* event will be generated. Additionally, if there is any pending received data, the *uart\_event\_type::UART\_RX\_RDY* event for that data will be generated before the *uart\_event\_type::UART\_RX\_BUF\_RELEASED* events.

**Parameters**

- dev – UART device structure.

**Return values**

- -ENOTSUP – If not supported.
- -EFAULT – There is no active reception.
- 0 – If successful, negative errno code otherwise.

int uart\_err\_check(const struct *device* \*dev)

Check whether an error was detected.

**Parameters**

- dev – UART device structure.

**Return values**

- uart\_rx\_stop\_reason – If error during receiving occurred.
- 0 – Otherwise.

int uart\_poll\_in(const struct *device* \*dev, unsigned char \*p\_char)

Poll the device for input.

**Parameters**

- dev – UART device structure.
- p\_char – Pointer to character.

**Return values**

- 0 – If a character arrived.
- -1 – If no character was available to read (i.e., the UART input buffer was empty).
- -ENOTSUP – If the operation is not supported.
- -EBUSY – If reception was enabled using `uart_rx_enabled`

`void uart_poll_out(const struct device *dev, unsigned char out_char)`

Output a character in polled mode.

This routine checks if the transmitter is empty. When the transmitter is empty, it writes a character to the data register.

To send a character when hardware flow control is enabled, the handshake signal CTS must be asserted.

#### Parameters

- `dev` – UART device structure.
- `out_char` – Character to send.

`int uart_configure(const struct device *dev, const struct uart\_config *cfg)`

Set UART configuration.

Sets UART configuration using data from `*cfg`.

#### Parameters

- `dev` – UART device structure.
- `cfg` – UART configuration structure.

#### Return values

- `-ENOSYS` – If configuration is not supported by device. or driver does not support setting configuration in runtime.
- `0` – If successful, negative `errno` code otherwise.

`int uart_config_get(const struct device *dev, struct uart\_config *cfg)`

Get UART configuration.

Stores current UART configuration to `*cfg`, can be used to retrieve initial configuration after device was initialized using data from DTS.

#### Parameters

- `dev` – UART device structure.
- `cfg` – UART configuration structure.

#### Return values

- `-ENOTSUP` – If driver does not support getting current configuration.
- `0` – If successful, negative `errno` code otherwise.

`static inline int uart_fifo_fill(const struct device *dev, const uint8_t *tx_data, int size)`

Fill FIFO with data.

This function is expected to be called from UART interrupt handler (ISR), if `uart_irq_tx_ready()` returns true. Result of calling this function not from an ISR is undefined (hardware-dependent). Likewise, *not* calling this function from an ISR if `uart_irq_tx_ready()` returns true may lead to undefined behavior, e.g. infinite interrupt loops. It's mandatory to test return value of this function, as different hardware has different FIFO depth (oftentimes just 1).

#### Parameters

- `dev` – UART device structure.
- `tx_data` – Data to transmit.
- `size` – Number of bytes to send.

**Returns** Number of bytes sent.

```
static inline int uart_fifo_read(const struct device *dev, uint8_t *rx_data, const int size)
```

Read data from FIFO.

This function is expected to be called from UART interrupt handler (ISR), if *uart\_irq\_rx\_ready()* returns true. Result of calling this function not from an ISR is undefined (hardware-dependent). It's unspecified whether "RX ready" condition as returned by *uart\_irq\_rx\_ready()* is level- or edge- triggered. That means that once *uart\_irq\_rx\_ready()* is detected, *uart\_fifo\_read()* must be called until it reads all available data in the FIFO (i.e. until it returns less data than was requested).

Note that the calling context only applies to physical UARTs and no to the virtual ones found in USB CDC ACM code.

#### Parameters

- *dev* – UART device structure.
- *rx\_data* – Data container.
- *size* – Container size.

**Returns** Number of bytes read.

```
void uart_irq_tx_enable(const struct device *dev)
```

Enable TX interrupt in IER.

#### Parameters

- *dev* – UART device structure.

**Returns** N/A

```
void uart_irq_tx_disable(const struct device *dev)
```

Disable TX interrupt in IER.

#### Parameters

- *dev* – UART device structure.

**Returns** N/A

```
static inline int uart_irq_tx_ready(const struct device *dev)
```

Check if UART TX buffer can accept a new char.

Check if UART TX buffer can accept at least one character for transmission (i.e. *uart\_fifo\_fill()* will succeed and return non-zero). This function must be called in a UART interrupt handler, or its result is undefined. Before calling this function in the interrupt handler, *uart\_irq\_update()* must be called once per the handler invocation.

#### Parameters

- *dev* – UART device structure.

#### Return values

- 1 – If at least one char can be written to UART.
- 0 – Otherwise.

```
void uart_irq_rx_enable(const struct device *dev)
```

Enable RX interrupt.

#### Parameters

- *dev* – UART device structure.

**Returns** N/A

```
void uart_irq_rx_disable(const struct device *dev)
```

Disable RX interrupt.

**Parameters**

- dev – UART device structure.

**Returns** N/A

```
static inline int uart_irq_tx_complete(const struct device *dev)
```

Check if UART TX block finished transmission.

Check if any outgoing data buffered in UART TX block was fully transmitted and TX block is idle. When this condition is true, UART device (or whole system) can be power off. Note that this function is *not* useful to check if UART TX can accept more data, use [uart\\_irq\\_tx\\_ready\(\)](#) for that. This function must be called in a UART interrupt handler, or its result is undefined. Before calling this function in the interrupt handler, [uart\\_irq\\_update\(\)](#) must be called once per the handler invocation.

**Parameters**

- dev – UART device structure.

**Return values**

- 1 – If nothing remains to be transmitted.
- 0 – Otherwise.
- -ENOTSUP – if this function is not supported

```
static inline int uart_irq_rx_ready(const struct device *dev)
```

Check if UART RX buffer has a received char.

Check if UART RX buffer has at least one pending character (i.e. [uart\\_fifo\\_read\(\)](#) will succeed and return non-zero). This function must be called in a UART interrupt handler, or its result is undefined. Before calling this function in the interrupt handler, [uart\\_irq\\_update\(\)](#) must be called once per the handler invocation. It's unspecified whether condition as returned by this function is level- or edge- triggered (i.e. if this function returns true when RX FIFO is non-empty, or when a new char was received since last call to it). See description of [uart\\_fifo\\_read\(\)](#) for implication of this.

**Parameters**

- dev – UART device structure.

**Return values**

- 1 – If a received char is ready.
- 0 – Otherwise.
- -ENOTSUP – if this function is not supported

```
void uart_irq_err_enable(const struct device *dev)
```

Enable error interrupt.

**Parameters**

- dev – UART device structure.

**Returns** N/A

```
void uart_irq_err_disable(const struct device *dev)
```

Disable error interrupt.

**Parameters**

- dev – UART device structure.

**Return values**

- 1 – If an IRQ is ready.
- 0 – Otherwise.

```
int uart_irq_is_pending(const struct device *dev)
```

Check if any IRQs is pending.

**Parameters**

- dev – UART device structure.

**Return values**

- 1 – If an IRQ is pending.
- 0 – Otherwise.

```
int uart_irq_update(const struct device *dev)
```

Start processing interrupts in ISR.

This function should be called the first thing in the ISR. Calling [uart\\_irq\\_rx\\_ready\(\)](#), [uart\\_irq\\_tx\\_ready\(\)](#), [uart\\_irq\\_tx\\_complete\(\)](#) allowed only after this.

The purpose of this function is:

- For devices with auto-acknowledge of interrupt status on register read to cache the value of this register (rx\_ready, etc. then use this case).
- For devices with explicit acknowledgement of interrupts, to ack any pending interrupts and likewise to cache the original value.
- For devices with implicit acknowledgement, this function will be empty. But the ISR must perform the actions needs to ack the interrupts (usually, call [uart\\_fifo\\_read\(\)](#) on rx\_ready, and [uart\\_fifo\\_fill\(\)](#) on tx\_ready).

**Parameters**

- dev – UART device structure.

**Return values** 1 – Always.

```
static inline void uart_irq_callback_user_data_set(const struct device *dev,  
                                                  uart\_irq\_callback\_user\_data\_t cb, void  
                                                  *user_data)
```

Set the IRQ callback function pointer.

This sets up the callback for IRQ. When an IRQ is triggered, the specified function will be called with specified user data. See description of [uart\\_irq\\_update\(\)](#) for the requirements on ISR.

**Parameters**

- dev – UART device structure.
- cb – Pointer to the callback function.
- user\_data – Data to pass to callback function.

**Returns** N/A

```
static inline void uart_irq_callback_set(const struct device *dev, uart\_irq\_callback\_user\_data\_t  
                                       cb)
```

Set the IRQ callback function pointer (legacy).

This sets up the callback for IRQ. When an IRQ is triggered, the specified function will be called with the device pointer.

**Parameters**

- `dev` – UART device structure.
- `cb` – Pointer to the callback function.

**Returns** N/A

```
int uart_line_ctrl_set(const struct device *dev, uint32_t ctrl, uint32_t val)
```

Manipulate line control for UART.

**Parameters**

- `dev` – UART device structure.
- `ctrl` – The line control to manipulate (see enum `uart_line_ctrl`).
- `val` – Value to set to the line control.

**Return values**

- 0 – If successful.
- `failed` – Otherwise.

```
int uart_line_ctrl_get(const struct device *dev, uint32_t ctrl, uint32_t *val)
```

Retrieve line control for UART.

**Parameters**

- `dev` – UART device structure.
- `ctrl` – The line control to retrieve (see enum `uart_line_ctrl`).
- `val` – Pointer to variable where to store the line control value.

**Return values**

- 0 – If successful.
- `failed` – Otherwise.

```
int uart_drv_cmd(const struct device *dev, uint32_t cmd, uint32_t p)
```

Send extra command to driver.

Implementation and accepted commands are driver specific. Refer to the drivers for more information.

**Parameters**

- `dev` – UART device structure.
- `cmd` – Command to driver.
- `p` – Parameter to the command.

**Return values**

- 0 – If successful.
- `failed` – Otherwise.

```
struct uart_event_tx
```

*#include <uart.h>* UART TX event data.

**Public Members**

```
const uint8_t *buf
```

Pointer to current buffer.

size\_t len

Number of bytes sent.

struct uart\_event\_rx

*#include <uart.h>* UART RX event data.

The data represented by the event is stored in rx.buf[rx.offset] to rx.buf[rx.offset+rx.len]. That is, the length is relative to the offset.

### Public Members

uint8\_t \*buf

Pointer to current buffer.

size\_t offset

Currently received data offset in bytes.

size\_t len

Number of new bytes received.

struct uart\_event\_rx\_buf

*#include <uart.h>* UART RX buffer released event data.

struct uart\_event\_rx\_stop

*#include <uart.h>* UART RX stopped data.

### Public Members

enum [uart\\_rx\\_stop\\_reason](#) reason

Reason why receiving stopped.

struct [uart\\_event\\_rx](#) data

Last received data.

struct uart\_event

*#include <uart.h>* Structure containing information about current event.

### Public Members

enum [uart\\_event\\_type](#) type

Type of event.

union uart\_event\_data

*#include <uart.h>* Event data.

## Public Members

struct `uart_event_tx` tx  
     [uart\\_event\\_type::UART\\_TX\\_DONE](#) and [uart\\_event\\_type::UART\\_TX\\_ABORTED](#) events data.

struct `uart_event_rx` rx  
     [uart\\_event\\_type::UART\\_RX\\_RDY](#) event data.

struct `uart_event_rx_buf` rx\_buf  
     [uart\\_event\\_type::UART\\_RX\\_BUF\\_RELEASED](#) event data.

struct `uart_event_rx_stop` rx\_stop  
     [uart\\_event\\_type::UART\\_RX\\_STOPPED](#) event data.

struct `uart_config`  
     #include <uart.h> UART controller configuration structure.  
     **Param baudrate** Baudrate setting in bps  
     **Param parity** Parity bit, use [uart\\_config\\_parity](#)  
     **Param stop\_bits** Stop bits, use [uart\\_config\\_stop\\_bits](#)  
     **Param data\_bits** Data bits, use [uart\\_config\\_data\\_bits](#)  
     **Param flow\_ctrl** Flow control setting, use [uart\\_config\\_flow\\_control](#)

struct `uart_device_config`  
     #include <uart.h> UART device configuration.  
     **Param port** Base port number  
     **Param base** Memory mapped base address  
     **Param regs** Register address  
     **Param sys\_clk\_freq** System clock frequency in Hz

struct `uart_driver_api`  
     #include <uart.h> Driver API structure.

## Public Members

int (\*poll\_in)(const struct [device](#) \*dev, unsigned char \*p\_char)  
     Console I/O function

int (\*err\_check)(const struct [device](#) \*dev)  
     Console I/O function

int (\*configure)(const struct [device](#) \*dev, const struct [uart\\_config](#) \*cfg)  
     UART configuration functions

int (\*fifo\_fill)(const struct [device](#) \*dev, const uint8\_t \*tx\_data, int len)  
     Interrupt driven FIFO fill function

`int (*fifo_read)(const struct device *dev, uint8_t *rx_data, const int size)`  
Interrupt driven FIFO read function

`void (*irq_tx_enable)(const struct device *dev)`  
Interrupt driven transfer enabling function

`void (*irq_tx_disable)(const struct device *dev)`  
Interrupt driven transfer disabling function

`int (*irq_tx_ready)(const struct device *dev)`  
Interrupt driven transfer ready function

`void (*irq_rx_enable)(const struct device *dev)`  
Interrupt driven receiver enabling function

`void (*irq_rx_disable)(const struct device *dev)`  
Interrupt driven receiver disabling function

`int (*irq_tx_complete)(const struct device *dev)`  
Interrupt driven transfer complete function

`int (*irq_rx_ready)(const struct device *dev)`  
Interrupt driven receiver ready function

`void (*irq_err_enable)(const struct device *dev)`  
Interrupt driven error enabling function

`void (*irq_err_disable)(const struct device *dev)`  
Interrupt driven error disabling function

`int (*irq_is_pending)(const struct device *dev)`  
Interrupt driven pending status function

`int (*irq_update)(const struct device *dev)`  
Interrupt driven interrupt update function

`void (*irq_callback_set)(const struct device *dev, uart_irq_callback_user_data_t cb, void *user_data)`  
Set the irq callback function

## 7.21.27 MDIO

### Overview

MDIO is a bus that is commonly used to communicate with ethernet PHY devices. Many ethernet MAC controllers also provide hardware to communicate over MDIO bus with a peripheral device.

This API is intended to be used primarily by PHY drivers but can also be used by user firmware.

## API Reference

*group* mdio\_interface

MDIO Interface.

### Functions

void mdio\_bus\_enable(const struct *device* \*dev)

Enable MDIO bus.

#### Parameters

- dev – **[in]** Pointer to the device structure for the controller

void mdio\_bus\_disable(const struct *device* \*dev)

Disable MDIO bus and tri-state drivers.

#### Parameters

- dev – **[in]** Pointer to the device structure for the controller

int mdio\_read(const struct *device* \*dev, uint8\_t prtad, uint8\_t devad, uint16\_t \*data)

Read from MDIO Bus.

This routine provides a generic interface to perform a read on the MDIO bus.

#### Parameters

- dev – **[in]** Pointer to the device structure for the controller
- prtad – **[in]** Port address
- devad – **[in]** Device address
- data – Pointer to receive read data

#### Return values

- 0 – If successful.
- -EIO – General input / output error.
- -ETIMEDOUT – If transaction timedout on the bus

int mdio\_write(const struct *device* \*dev, uint8\_t prtad, uint8\_t devad, uint16\_t data)

Write to MDIO bus.

This routine provides a generic interface to perform a write on the MDIO bus.

#### Parameters

- dev – **[in]** Pointer to the device structure for the controller
- prtad – **[in]** Port address
- devad – **[in]** Device address
- data – **[in]** Data to write

#### Return values

- 0 – If successful.
- -EIO – General input / output error.
- -ETIMEDOUT – If transaction timedout on the bus

## 7.21.28 Watchdog

### Overview

### API Reference

*group* watchdog\_interface

Watchdog Interface.

#### Watchdog Reset Behavior.

Reset behavior after timeout.

WDT\_FLAG\_RESET\_NONE

No reset

WDT\_FLAG\_RESET\_CPU\_CORE

CPU core reset

WDT\_FLAG\_RESET\_SOC

Global SoC reset

#### Defines

WDT\_OPT\_PAUSE\_IN\_SLEEP

Pause watchdog timer when CPU is in sleep state.

WDT\_OPT\_PAUSE\_HALTED\_BY\_DBG

Pause watchdog timer when CPU is halted by the debugger.

WDT\_FLAG\_RESET\_SHIFT

Watchdog reset flag bit field mask shift.

WDT\_FLAG\_RESET\_MASK

Watchdog reset flag bit field mask.

#### Typedefs

typedef void (\*wdt\_callback\_t)(const struct *device* \*dev, int channel\_id)

Watchdog callback.

typedef int (\*wdt\_api\_setup)(const struct *device* \*dev, uint8\_t options)

Callback API for setting up watchdog instance. See [wdt\\_setup\(\)](#) for argument descriptions.

typedef int (\*wdt\_api\_disable)(const struct *device* \*dev)

Callback API for disabling watchdog instance. See [wdt\\_disable\(\)](#) for argument descriptions.

```
typedef int (*wdt_api_install_timeout)(const struct device *dev, const struct wdt\_timeout\_cfg *cfg)
```

Callback API for installing new timeout. See [wdt\\_install\\_timeout\(\)](#) for argument descriptions.

```
typedef int (*wdt_api_feed)(const struct device *dev, int channel_id)
```

Callback API for feeding specified watchdog timeout. See [\(wdt\\_feed\)](#) for argument descriptions.

## Functions

```
int wdt_setup(const struct device *dev, uint8_t options)
```

Set up watchdog instance.

This function is used for configuring global watchdog settings that affect all timeouts. It should be called after installing timeouts. After successful return, all installed timeouts are valid and must be serviced periodically by calling [wdt\\_feed\(\)](#).

### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `options` – Configuration options as defined by the `WDT_OPT_*` constants

### Return values

- 0 – If successful.
- `-ENOTSUP` – If any of the set options is not supported.
- `-EBUSY` – If watchdog instance has been already setup.

```
int wdt_disable(const struct device *dev)
```

Disable watchdog instance.

This function disables the watchdog instance and automatically uninstalls all timeouts. To set up a new watchdog, install timeouts and call [wdt\\_setup\(\)](#) again. Not all watchdogs can be restarted after they are disabled.

### Parameters

- `dev` – Pointer to the device structure for the driver instance.

### Return values

- 0 – If successful.
- `-EFAULT` – If watchdog instance is not enabled.
- `-EPERM` – If watchdog can not be disabled directly by application code.

```
static inline int wdt_install_timeout(const struct device *dev, const struct wdt\_timeout\_cfg *cfg)
```

Install new timeout.

This function must be used before [wdt\\_setup\(\)](#). Changes applied here have no effects until [wdt\\_setup\(\)](#) is called.

### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `cfg` – Pointer to timeout configuration structure.

### Return values

- `channel_id` – If successful, a non-negative value indicating the index of the channel to which the timeout was assigned. This value is supposed to be used as the parameter in calls to [wdt\\_feed\(\)](#).

- `-EBUSY` – If timeout can not be installed while watchdog has already been setup.
- `-ENOMEM` – If no more timeouts can be installed.
- `-ENOTSUP` – If any of the set flags is not supported.
- `-EINVAL` – If any of the window timeout value is out of possible range. This value is also returned if watchdog supports only one timeout value for all timeouts and the supplied timeout window differs from windows for alarms installed so far.

```
int wdt_feed(const struct device *dev, int channel_id)
```

Feed specified watchdog timeout.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `channel_id` – Index of the fed channel.

#### Return values

- 0 – If successful.
- `-EAGAIN` – If completing the feed operation would stall the caller, for example due to an in-progress watchdog operation such as a previous `wdt_feed()`.
- `-EINVAL` – If there is no installed timeout for supplied channel.

```
struct wdt_window
```

`#include <watchdog.h>` Watchdog timeout window.

Each installed timeout needs feeding within the specified time window, otherwise the watchdog will trigger. If the watchdog instance does not support window timeouts then min value must be equal to 0.

---

**Note:** If specified values can not be precisely set they are always rounded up.

---

**Param min** Lower limit of watchdog feed timeout in milliseconds.

**Param max** Upper limit of watchdog feed timeout in milliseconds.

```
struct wdt_timeout_cfg
```

`#include <watchdog.h>` Watchdog timeout configuration struct.

**Param window** Timing parameters of watchdog timeout.

**Param callback** Timeout callback. Passing NULL means that no callback will be run.

**Param next** Pointer to the next timeout configuration. This pointer is used for watchdogs with staged timeouts functionality. Value must be NULL for single stage timeout.

**Param flags** Bit field with following parts:

```
reset      [ 0 : 1 ] - perform specified reset after timeout/  
↪callback
```

## 7.21.29 Video

The video driver API offers a generic interface to video devices.

## Basic Operation

**Video Device** A video device is the abstraction of a hardware or software video function, which can produce, process, consume or transform video data. The video API is designed to offer flexible way to create, handle and combine various video devices.

**Endpoint** Each video device can have one or more endpoints. Output endpoints configure video output function and generate data. Input endpoints configure video input function and consume data.

**Video Buffer** A video buffer provides the transport mechanism for the data. There is no particular requirement on the content. The requirement for the content is defined by the endpoint format. A video buffer can be queued to a device endpoint for filling (input ep) or consuming (output ep) operation, once the operation is achieved, buffer can be dequeued for post-processing, release or reuse.

**Controls** A video control is accessed and identified by a CID (control identifier). It represents a video control property. Different devices will have different controls available which can be generic, related to a device class or vendor specific. The set/get control functions provide a generic scalable interface to handle and create controls.

## Configuration Options

Related configuration options:

- `:kconfig: `CONFIG_VIDEO``

## API Reference

## Typedefs

typedef int (\*video\_api\_set\_format\_t)(const struct [device](#) \*dev, enum [video\\_endpoint\\_id](#) ep, struct [video\\_format](#) \*fmt)

Set video format See [video\\_set\\_format\(\)](#) for argument descriptions.

typedef int (\*video\_api\_get\_format\_t)(const struct [device](#) \*dev, enum [video\\_endpoint\\_id](#) ep, struct [video\\_format](#) \*fmt)

get current video format See [video\\_get\\_format\(\)](#) for argument descriptions.

typedef int (\*video\_api\_enqueue\_t)(const struct [device](#) \*dev, enum [video\\_endpoint\\_id](#) ep, struct [video\\_buffer](#) \*\*buf)

Enqueue a buffer in the driver's incoming queue. See [video\\_enqueue\(\)](#) for argument descriptions.

typedef int (\*video\_api\_dequeue\_t)(const struct [device](#) \*dev, enum [video\\_endpoint\\_id](#) ep, struct [video\\_buffer](#) \*\*buf, [k\\_timeout\\_t](#) timeout)

Dequeue a buffer from the driver's outgoing queue. See [video\\_dequeue\(\)](#) for argument descriptions.

typedef int (\*video\_api\_flush\_t)(const struct [device](#) \*dev, enum [video\\_endpoint\\_id](#) ep, bool cancel)

Flush endpoint buffers, buffer are moved from incoming queue to outgoing queue. See [video\\_flush\(\)](#) for argument descriptions.

typedef int (\*video\_api\_stream\_start\_t)(const struct [device](#) \*dev)

Start the capture or output process. See [video\\_stream\\_start\(\)](#) for argument descriptions.

typedef int (\*video\_api\_stream\_stop\_t)(const struct [device](#) \*dev)

Stop the capture or output process. See [video\\_stream\\_stop\(\)](#) for argument descriptions.

typedef int (\*video\_api\_set\_ctrl\_t)(const struct [device](#) \*dev, unsigned int cid, void \*value)

set a video control value. See [video\\_set\\_ctrl\(\)](#) for argument descriptions.

typedef int (\*video\_api\_get\_ctrl\_t)(const struct [device](#) \*dev, unsigned int cid, void \*value)

get a video control value. See [video\\_get\\_ctrl\(\)](#) for argument descriptions.

typedef int (\*video\_api\_get\_caps\_t)(const struct [device](#) \*dev, enum [video\\_endpoint\\_id](#) ep, struct [video\\_caps](#) \*caps)

Get capabilities of a video endpoint. See [video\\_get\\_caps\(\)](#) for argument descriptions.

typedef int (\*video\_api\_set\_signal\_t)(const struct [device](#) \*dev, enum [video\\_endpoint\\_id](#) ep, struct [k\\_poll\\_signal](#) \*signal)

Register/Unregister poll signal for buffer events. See [video\\_set\\_signal\(\)](#) for argument descriptions.

## Enums

enum video\_endpoint\_id

video\_endpoint\_id enum Identify the video device endpoint.

*Values:*

enumerator VIDEO\_EP\_NONE

enumerator VIDEO\_EP\_ANY

enumerator VIDEO\_EP\_IN

enumerator VIDEO\_EP\_OUT

enum video\_signal\_result

video\_event enum Identify video event.

*Values:*

enumerator VIDEO\_BUF\_DONE

enumerator VIDEO\_BUF\_ABORTED

enumerator VIDEO\_BUF\_ERROR

## Functions

static inline int video\_set\_format(const struct [device](#) \*dev, enum [video\\_endpoint\\_id](#) ep, struct [video\\_format](#) \*fmt)

Set video format.

Configure video device with a specific format.

### Parameters

- dev – Pointer to the device structure for the driver instance.
- ep – Endpoint ID.
- fmt – Pointer to a video format struct.

### Return values

- 0 – Is successful.
- -EINVAL – If parameters are invalid.
- -ENOTSUP – If format is not supported.
- -EIO – General input / output error.

```
static inline int video_get_format(const struct device *dev, enum video_endpoint_id ep, struct video_format *fmt)
```

Get video format.

Get video device current video format.

#### Parameters

- dev – Pointer to the device structure for the driver instance.
- ep – Endpoint ID.
- fmt – Pointer to video format struct.

**Return values** pointer – to video format

```
static inline int video_enqueue(const struct device *dev, enum video_endpoint_id ep, struct video_buffer *buf)
```

Enqueue a video buffer.

Enqueue an empty (capturing) or filled (output) video buffer in the driver's endpoint incoming queue.

#### Parameters

- dev – Pointer to the device structure for the driver instance.
- ep – Endpoint ID.
- buf – Pointer to the video buffer.

#### Return values

- 0 – Is successful.
- -EINVAL – If parameters are invalid.
- -EIO – General input / output error.

```
static inline int video_dequeue(const struct device *dev, enum video_endpoint_id ep, struct video_buffer **buf, k_timeout_t timeout)
```

Dequeue a video buffer.

Dequeue a filled (capturing) or displayed (output) buffer from the driver's endpoint outgoing queue.

#### Parameters

- dev – Pointer to the device structure for the driver instance.
- ep – Endpoint ID.
- buf – Pointer a video buffer pointer.
- timeout – Timeout

#### Return values

- 0 – Is successful.
- -EINVAL – If parameters are invalid.
- -EIO – General input / output error.

```
static inline int video_flush(const struct device *dev, enum video_endpoint_id ep, bool cancel)
```

Flush endpoint buffers.

A call to flush finishes when all endpoint buffers have been moved from incoming queue to outgoing queue. Either because canceled or fully processed through the video function.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `ep` – Endpoint ID.
- `cancel` – If true, cancel buffer processing instead of waiting for completion.

**Return values** 0 – Is successful, -ERRNO code otherwise.

static inline int `video_stream_start`(const struct *device* \*dev)

Start the video device function.

`video_stream_start` is called to enter ‘streaming’ state (capture, output...). The driver may receive buffers with *video\_enqueue()* before `video_stream_start` is called. If driver/device needs a minimum number of buffers before being able to start streaming, then driver set the `min_vbuf_count` to the related endpoint capabilities.

**Return values**

- 0 – Is successful.
- -EIO – General input / output error.

static inline int `video_stream_stop`(const struct *device* \*dev)

Stop the video device function.

On `video_stream_stop`, driver must stop any transactions or wait until they finish.

**Return values**

- 0 – Is successful.
- -EIO – General input / output error.

static inline int `video_get_caps`(const struct *device* \*dev, enum *video\_endpoint\_id* ep, struct *video\_caps* \*caps)

Get the capabilities of a video endpoint.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.
- `ep` – Endpoint ID.
- `caps` – Pointer to the *video\_caps* struct to fill.

**Return values** 0 – Is successful, -ERRNO code otherwise.

static inline int `video_set_ctrl`(const struct *device* \*dev, unsigned int cid, void \*value)

Set the value of a control.

This set the value of a video control, value type depends on control ID, and must be interpreted accordingly.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.
- `cid` – Control ID.
- `value` – Pointer to the control value.

**Return values**

- 0 – Is successful.
- -EINVAL – If parameters are invalid.
- -ENOTSUP – If format is not supported.
- -EIO – General input / output error.

```
static inline int video_get_ctrl(const struct device *dev, unsigned int cid, void *value)
```

Get the current value of a control.

This retrieve the value of a video control, value type depends on control ID, and must be interpreted accordingly.

#### Parameters

- *dev* – Pointer to the device structure for the driver instance.
- *cid* – Control ID.
- *value* – Pointer to the control value.

#### Return values

- 0 – Is successful.
- -EINVAL – If parameters are invalid.
- -ENOTSUP – If format is not supported.
- -EIO – General input / output error.

```
static inline int video_set_signal(const struct device *dev, enum video_endpoint_id ep, struct k_poll_signal *signal)
```

Register/Unregister *k\_poll* signal for a video endpoint.

Register a poll signal to the endpoint, which will be signaled on frame completion (done, aborted, error). Registering a NULL poll signal unregisters any previously registered signal.

#### Parameters

- *dev* – Pointer to the device structure for the driver instance.
- *ep* – Endpoint ID.
- *signal* – Pointer to *k\_poll\_signal*

**Return values** 0 – Is successful, -ERRNO code otherwise.

```
struct video_buffer *video_buffer_alloc(size_t size)
```

Allocate video buffer.

#### Parameters

- *size* – Size of the video buffer.

**Return values** *pointer* – to allocated video buffer

```
void video_buffer_release(struct video_buffer *buf)
```

Release a video buffer.

#### Parameters

- *buf* – Pointer to the video buffer to release.

```
struct video_format
```

*#include <video.h>* video format structure

Used to configure frame format.

**Param *pixelformat*** is the fourcc pixel format value.

**Param *width*** is the frame width in pixels.

**Param *height*** is the frame height in pixels.

**Param *pitch*** is the line stride, the number of bytes that needs to be added to the address in the first pixel of a row in order to go to the address of the first pixel of the next row ( $\geq$  width).

struct video\_format\_cap

*#include <video.h>* video format capability

Used to describe a video endpoint format capability.

**Param pixelformat** is a list of supported pixel formats (0 terminated).

**Param width\_min** is the minimum supported frame width.

**Param width\_max** is the maximum supported frame width.

**Param height\_min** is the minimum supported frame width.

**Param height\_max** is the maximum supported frame width.

**Param width\_step** is the width step size.

**Param height\_step** is the height step size.

struct video\_caps

*#include <video.h>* video capabilities

Used to describe video endpoint capabilities.

**Param format\_caps** is a list of video format capabilities (zero terminated).

**Param min\_vbuf\_count** is the minimal count of video buffers to enqueue before being able to start the stream.

struct video\_buffer

*#include <video.h>* video buffer structure

Represent a video frame.

**Param driver\_data** is a pointer to driver specific data.

**Param buffer** is a pointer to the start of the buffer.

**Param size** is the size in bytes of the buffer.

**Param bytesused** is the number of bytes occupied by the valid data in the buffer.

**Param timestamp** is a time reference in milliseconds at which the last data byte was actually received for input endpoints or to be consumed for output endpoints.

struct video\_driver\_api

*#include <video.h>*

group video\_controls

Video controls.

### 7.21.30 eSPI

#### Overview

The eSPI (enhanced serial peripheral interface) is a serial bus that is based on SPI. It also features a four-wire interface (receive, transmit, clock and slave select) and three configurations: single IO, dual IO and quad IO.

The technical advancements include lower voltage signal levels (1.8V vs. 3.3V), lower pin count, and the frequency is twice as fast (66MHz vs. 33MHz) Because of its enhancements, the eSPI is used to replace the LPC (lower pin count) interface, SPI, SMBus and sideband signals.

See [eSPI interface specification](#) for additional details.

#### API Reference

*group* `espi_interface`

eSPI Driver APIs

eSPI SAF Driver APIs

## Defines

HOST\_KBC\_EVT\_IBF

HOST\_KBC\_EVT\_OBE

## Typedefs

```
typedef void (*espi_callback_handler_t)(const struct device *dev, struct espi_callback *cb,
struct espi_event espi_evt)
```

Define the application callback handler function signature.

**Param dev** Device struct for the eSPI device.

**Param cb** Original struct `espi_callback` owning this handler.

**Param `espi_evt`** event details that trigger the callback handler.

## Enums

```
enum espi_io_mode
```

## eSPI I/O mode capabilities

*Values:*

```
enumerator ESPI_IO_MODE_SINGLE_LINE = BIT(0)
```

```
enumerator ESPI_IO_MODE_DUAL_LINES = BIT(1)
```

```
enumerator ESPI_IO_MODE_QUAD_LINES = BIT(2)
```

```
enum espi_channel
```

eSPI channel.

[illegible]

Identifies each eSPI logical channel supported by eSPI controller. Each channel allows independent traffic, but the assignment of channel type to channel number is fixed.

Note that generic commands are not associated with any channel, so traffic over eSPI can occur if all channels are disabled or not ready.

*Values:*

enumerator ESPI\_CHANNEL\_PERIPHERAL = *BIT*(0)

enumerator ESPI\_CHANNEL\_VWIRE = *BIT*(1)

enumerator ESPI\_CHANNEL\_OOB = *BIT*(2)

enumerator ESPI\_CHANNEL\_FLASH = *BIT*(3)

enum espi\_bus\_event

eSPI bus event.

eSPI bus event to indicate events for which user can register callbacks.

*Values:*

## Functions

`int espi_config(const struct device *dev, struct espi\_cfg *cfg)`

Configure operation of a eSPI controller.

This routine provides a generic interface to override eSPI controller capabilities.

If this eSPI controller is acting as slave, the values set here will be discovered as part through the GET\_CONFIGURATION command issued by the eSPI master during initialization.

If this eSPI controller is acting as master, the values set here will be used by eSPI master to determine minimum common capabilities with eSPI slave then send via SET\_CONFIGURATION command.

```
+-----+ +-----+ +-----+ +-----+ +-----+ + eSPI
| | eSPI | | eSPI | | eSPI | | eSPI | | slave | | driver | | bus | | driver | | host |
+-----+ +-----+ +-----+ +-----+ +-----+ + | |
| | | espi_config | Set eSPI | Set eSPI | espi_config | +-----+ ctrl regs | cap ctrl
reg | +-----+ +-----+ +-----+ +-----+ +-----+ + |
```

	<-----+ +-----+>	
	GET_CONFIGURATION	

```
| | +<-----&#8212;+ | | |<-----&#8212;| | | | eSPI caps | | | |
|-----&#8212;>+ response | | | | |-----&#8212;>+ | | | | | | | |
SET_CONFIGURATION | | | | +<-----&#8212;+ | | | | accept | | | |
+-----&#8212;>+ |
```

- + + + +

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `cfg` – the device runtime configuration for the eSPI controller.

#### Return values

- 0 – If successful.
- -EIO – General input / output error, failed to configure device.
- -EINVAL – invalid capabilities, failed to configure device.
- -ENOTSUP – capability not supported by eSPI slave.

`bool espi_get_channel_status(const struct device *dev, enum espi\_channel ch)`

Query to see if it a channel is ready.

This routine allows to check if logical channel is ready before use. Note that queries for channels not supported will always return false.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `ch` – the eSPI channel for which status is to be retrieved.

#### Return values

- `true` – If eSPI channel is ready.
- `false` – otherwise.

`int espi_read_request(const struct device *dev, struct espi\_request\_packet *req)`

Sends memory, I/O or message read request over eSPI.

This routines provides a generic interface to send a read request packet.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `req` – Address of structure representing a memory, I/O or message read request.

#### Return values

- 0 – If successful.
- -ENOTSUP – if eSPI controller doesn't support raw packets and instead low memory transactions are handled by controller hardware directly.
- -EIO – General input / output error, failed to send over the bus.

`int espi_write_request(const struct device *dev, struct espi\_request\_packet *req)`

Sends memory, I/O or message write request over eSPI.

This routines provides a generic interface to send a write request packet.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `req` – Address of structure representing a memory, I/O or message write request.

**Return values**

- 0 – If successful.
- -ENOTSUP – if eSPI controller doesn't support raw packets and instead low memory transactions are handled by controller hardware directly.
- -EINVAL – General input / output error, failed to send over the bus.

```
int espi_read_lpc_request(const struct device *dev, enum lpc_peripheral_opcode op, uint32_t *data)
```

Reads SOC data from a LPC peripheral with information updated over eSPI.

This routine provides a generic interface to read a block whose information was updated by an eSPI transaction. Reading may trigger a transaction. The eSPI packet is assembled by the HW block.

**Parameters**

- dev – Pointer to the device structure for the driver instance.
- op – Enum representing opcode for peripheral type and read request.
- data – Parameter to be read from to the LPC peripheral.

**Return values**

- 0 – If successful.
- -ENOTSUP – if eSPI peripheral is off or not supported.
- -EINVAL – for unimplemented lpc opcode, but in range.

```
int espi_write_lpc_request(const struct device *dev, enum lpc_peripheral_opcode op, uint32_t *data)
```

Writes data to a LPC peripheral which generates an eSPI transaction.

This routine provides a generic interface to write data to a block which triggers an eSPI transaction. The eSPI packet is assembled by the HW block.

**Parameters**

- dev – Pointer to the device structure for the driver instance.
- op – Enum representing an opcode for peripheral type and write request.
- data – Represents the parameter passed to the LPC peripheral.

**Return values**

- 0 – If successful.
- -ENOTSUP – if eSPI peripheral is off or not supported.
- -EINVAL – for unimplemented lpc opcode, but in range.

```
int espi_send_vwire(const struct device *dev, enum espi_vwire_signal signal, uint8_t level)
```

Sends system/platform signal as a virtual wire packet.

This routines provides a generic interface to send a virtual wire packet from slave to master.

**Parameters**

- dev – Pointer to the device structure for the driver instance.
- signal – The signal to be send to eSPI master.
- level – The level of signal requested LOW or HIGH.

**Return values**

- 0 – If successful.

- -EIO – General input / output error, failed to send over the bus.

int espi\_receive\_vwire(const struct [device](#) \*dev, enum [espi\\_vwire\\_signal](#) signal, uint8\_t \*level)

Retrieves level status for a signal encapsulated in a virtual wire.

This routines provides a generic interface to request a virtual wire packet from eSPI master and retrieve the signal level.

#### Parameters

- dev – Pointer to the device structure for the driver instance.
- signal – the signal to be requested from eSPI master.
- level – the level of signal requested 0b LOW, 1b HIGH.

**Return values** -EIO – General input / output error, failed request to master.

int espi\_send\_oob(const struct [device](#) \*dev, struct [espi\\_oob\\_packet](#) \*pkt)

Sends SMBus transaction (out-of-band) packet over eSPI bus.

This routines provides an interface to encapsulate a SMBus transaction and send into packet over eSPI bus

#### Parameters

- dev – Pointer to the device structure for the driver instance.
- pkt – Address of the packet representation of SMBus transaction.

**Return values** -EIO – General input / output error, failed request to master.

int espi\_receive\_oob(const struct [device](#) \*dev, struct [espi\\_oob\\_packet](#) \*pkt)

Receives SMBus transaction (out-of-band) packet from eSPI bus.

This routines provides an interface to receive and decoded a SMBus transaction from eSPI bus

#### Parameters

- dev – Pointer to the device structure for the driver instance.
- pkt – Address of the packet representation of SMBus transaction.

**Return values** -EIO – General input / output error, failed request to master.

int espi\_read\_flash(const struct [device](#) \*dev, struct [espi\\_flash\\_packet](#) \*pkt)

Sends a read request packet for shared flash.

This routines provides an interface to send a request to read the flash component shared between the eSPI master and eSPI slaves.

#### Parameters

- dev – Pointer to the device structure for the driver instance.
- pkt – Address of the representation of read flash transaction.

#### Return values

- -ENOTSUP – eSPI flash logical channel transactions not supported.
- -EBUSY – eSPI flash channel is not ready or disabled by master.
- -EIO – General input / output error, failed request to master.

int espi\_write\_flash(const struct [device](#) \*dev, struct [espi\\_flash\\_packet](#) \*pkt)

Sends a write request packet for shared flash.

This routines provides an interface to send a request to write to the flash components shared between the eSPI master and eSPI slaves.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `pckt` – Address of the representation of write flash transaction.

#### Return values

- `-ENOTSUP` – eSPI flash logical channel transactions not supported.
- `-EBUSY` – eSPI flash channel is not ready or disabled by master.
- `-EIO` – General input / output error, failed request to master.

`int espi_flash_erase(const struct device *dev, struct espi\_flash\_packet *pckt)`

Sends a write request packet for shared flash.

This routines provides an interface to send a request to write to the flash components shared between the eSPI master and eSPI slaves.

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `pckt` – Address of the representation of write flash transaction.

#### Return values

- `-ENOTSUP` – eSPI flash logical channel transactions not supported.
- `-EBUSY` – eSPI flash channel is not ready or disabled by master.
- `-EIO` – General input / output error, failed request to master.

`static inline void espi_init_callback(struct espi_callback *callback, espi\_callback\_handler\_t handler, enum espi\_bus\_event evt_type)`

Helper to initialize a struct `espi_callback` properly.

Callback model

```

- power mgmt policy | | |

#### Parameters

- `callback` – A valid Application’s callback structure pointer.
- `handler` – A valid handler function pointer.
- `evt_type` – indicates the eSPI event relevant for the handler. for `VWIRE_RECEIVED` event the data will indicate the new level asserted

static inline int espi\_add\_callback(const struct [device](#) \*dev, struct espi\_callback \*callback)  
Add an application callback.

Note: enables to add as many callback as needed on the same device.

---

**Note:** Callbacks may be added to the device from within a callback handler invocation, but whether they are invoked for the current eSPI event is not specified.

---

#### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `callback` – A valid Application’s callback structure pointer.

**Returns** 0 if successful, negative errno code on failure.

```
static inline int espi_remove_callback(const struct device *dev, struct espi_callback *callback)
```

Remove an application callback.

Note: enables to remove as many callbacks as added through *espi\_add\_callback()*.

**Warning:** It is explicitly permitted, within a callback handler, to remove the registration for the callback that is running, i.e. *callback*. Attempts to remove other registrations on the same device may result in undefined behavior, including failure to invoke callbacks that remain registered and unintended invocation of removed callbacks.

#### Parameters

- *dev* – Pointer to the device structure for the driver instance.
- *callback* – A valid application's callback structure pointer.

**Returns** 0 if successful, negative *errno* code on failure.

```
int espi_saf_config(const struct device *dev, const struct espi_saf_cfg *cfg)
```

Configure operation of a eSPI controller.

This routine provides a generic interface to override eSPI controller capabilities.

If this eSPI controller is acting as slave, the values set here will be discovered as part through the GET\_CONFIGURATION command issued by the eSPI master during initialization.

If this eSPI controller is acting as master, the values set here will be used by eSPI master to determine minimum common capabilities with eSPI slave then send via SET\_CONFIGURATION command.

```

reg | +-----+ +-----+ +-----+ +-----+ +-----+ |
```

	<-----+ +-----+>	
	GET_CONFIGURATION	

```
| | +<-----+ +-----+ | | |<-----+ +-----+ | eSPI caps | | |
|-----+ + response | | | |-----+ +-----+ | | | | |
SET_CONFIGURATION | | | +<-----+ +-----+ | | | | accept | | |
+-----+ +-----+ +-----+ +-----+ +-----+ |
```

- + + + +

#### Parameters

- *dev* – Pointer to the device structure for the driver instance.
- *cfg* – the device runtime configuration for the eSPI controller.

#### Return values

- 0 – If successful.
- -EIO – General input / output error, failed to configure device.

- -EINVAL – invalid capabilities, failed to configure device.
- -ENOTSUP – capability not supported by eSPI slave.

```
int espi_saf_set_protection_regions(const struct device *dev, const struct espi_saf_protection
                                   *pr)
```

Set one or more SAF protection regions.

This routine provides an interface to override the default flash protection regions of the SAF controller.

#### Parameters

- dev – Pointer to the device structure for the driver instance.
- pr – Pointer to the SAF protection region structure.

#### Return values

- 0 – If successful.
- -EIO – General input / output error, failed to configure device.
- -EINVAL – invalid capabilities, failed to configure device.
- -ENOTSUP – capability not supported by eSPI slave.

```
int espi_saf_activate(const struct device *dev)
```

Activate SAF block.

This routine activates the SAF block and should only be called after SAF has been configured and the eSPI Master has enabled the Flash Channel.

#### Parameters

- dev – Pointer to the device structure for the driver instance.

#### Return values

- 0 – If successful
- -EINVAL – if failed to activate SAF.

```
bool espi_saf_get_channel_status(const struct device *dev)
```

Query to see if SAF is ready.

This routine allows to check if SAF is ready before use.

#### Parameters

- dev – Pointer to the device structure for the driver instance.

#### Return values

- true – If eSPI SAF is ready.
- false – otherwise.

```
int espi_saf_flash_read(const struct device *dev, struct espi_saf_packet *pkt)
```

Sends a read request packet for slave attached flash.

This routines provides an interface to send a request to read the flash component shared between the eSPI master and eSPI slaves.

#### Parameters

- dev – Pointer to the device structure for the driver instance.
- pkt – Address of the representation of read flash transaction.

#### Return values

- -ENOTSUP – eSPI flash logical channel transactions not supported.

- -EBUSY – eSPI flash channel is not ready or disabled by master.
- -EIO – General input / output error, failed request to master.

```
int espi_saf_flash_write(const struct device *dev, struct espi_saf_packet *pckt)
```

Sends a write request packet for slave attached flash.

This routines provides an interface to send a request to write to the flash components shared between the eSPI master and eSPI slaves.

## Parameters

- dev – Pointer to the device structure for the driver instance.
- pkt – Address of the representation of write flash transaction.

## Return values

- -ENOTSUP – eSPI flash logical channel transactions not supported.
- -EBUSY – eSPI flash channel is not ready or disabled by master.
- -EIO – General input / output error, failed request to master.

```
int espi_saf_flash_erase(const struct device *dev, struct espi_saf_packet *pckt)
```

Sends a write request packet for slave attached flash.

This routines provides an interface to send a request to write to the flash components shared between the eSPI master and eSPI slaves.

## Parameters

- dev – Pointer to the device structure for the driver instance.
- pkt – Address of the representation of erase flash transaction.

## Return values

- -ENOTSUP – eSPI flash logical channel transactions not supported.
- -EBUSY – eSPI flash channel is not ready or disabled by master.
- -EIO – General input / output error, failed request to master.

```
static inline void espi_saf_init_callback(struct espi_callback *callback,
                                         espi_callback_handler_t handler, enum espi_bus_event
                                         evt type)
```

Helper to initialize a struct `espi` callback properly.

## Callback model

```

+-----+> +-----+> +-----+> +-----+> | App

## Parameters

- `callback` – A valid Application's callback structure pointer.
- `handler` – A valid handler function pointer.
- `evt_type` – indicates the eSPI event relevant for the handler. for VWIRE\_RECEIVED event the data will indicate the new level asserted

static inline int espi\_saf\_add\_callback(const struct *device* \*dev, struct espi\_callback \*callback)  
Add an application callback.

Note: enables to add as many callback as needed on the same device.

**Note:** Callbacks may be added to the device from within a callback handler invocation, but whether they are invoked for the current eSPI event is not specified.

## Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `callback` – A valid Application's callback structure pointer.

**Returns** 0 if successful, negative errno code on failure.

```
static inline int espi_saf_remove_callback(const struct device *dev, struct espi_callback
                                         *callback)
```

Remove an application callback.

Note: enables to remove as many callbacks as added through *espi\_add\_callback()*.

**Warning:** It is explicitly permitted, within a callback handler, to remove the registration for the callback that is running, i.e. `callback`. Attempts to remove other registrations on the same device may result in undefined behavior, including failure to invoke callbacks that remain registered and unintended invocation of removed callbacks.

### Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `callback` – A valid application's callback structure pointer.

**Returns** 0 if successful, negative `errno` code on failure.

```
struct espi_evt_data_kbc
```

*#include <espi.h>* Bit field definition of `evt_data` in struct *espi\_event* for KBC.

```
struct espi_evt_data_acpi
```

*#include <espi.h>* Bit field definition of `evt_data` in struct *espi\_event* for ACPI.

```
struct espi_event
```

*#include <espi.h>* eSPI event

### Public Members

```
enum espi_bus_event evt_type

```

## 7.22 Power Management

Zephyr RTOS power management subsystem provides several means for a system integrator to implement power management support that can take full advantage of the power saving features of SOC.

### 7.22.1 Terminology

**SOC interface** This is a general term for the components that have knowledge of the SOC and provide interfaces to the hardware features. It will abstract the SOC specific implementations to the applications and the OS.

**Idle Thread** A system thread that runs when there are no other threads ready to run.

**Power gating** Power gating reduces power consumption by shutting off current to blocks of the integrated circuit that are not in use.

**Power State** SOC Power State describes processor and device power states implemented at the SOC level. Power states are represented by `pm_state` and each one has a different meaning.

**Device Runtime Power Management** Device Runtime Power Management (PM) refers the capability of devices be able of saving energy independently of the the system. Devices will keep reference of their usage and will automatically be suspended or resumed. This feature is enabled via the `::kconfig: `CONFIG_PM_DEVICE_RUNTIME`` Kconfig option.

### 7.22.2 Overview

The interfaces and APIs provided by the power management subsystem are designed to be architecture and SOC independent. This enables power management implementations to be easily adapted to different SOC and architectures.

The architecture and SOC independence is achieved by separating the core infrastructure and the SOC specific implementations. The SOC specific implementations are abstracted to the application and the OS using hardware abstraction layers.

The power management features are classified into the following categories.

- System Power Management
- Device Power Management

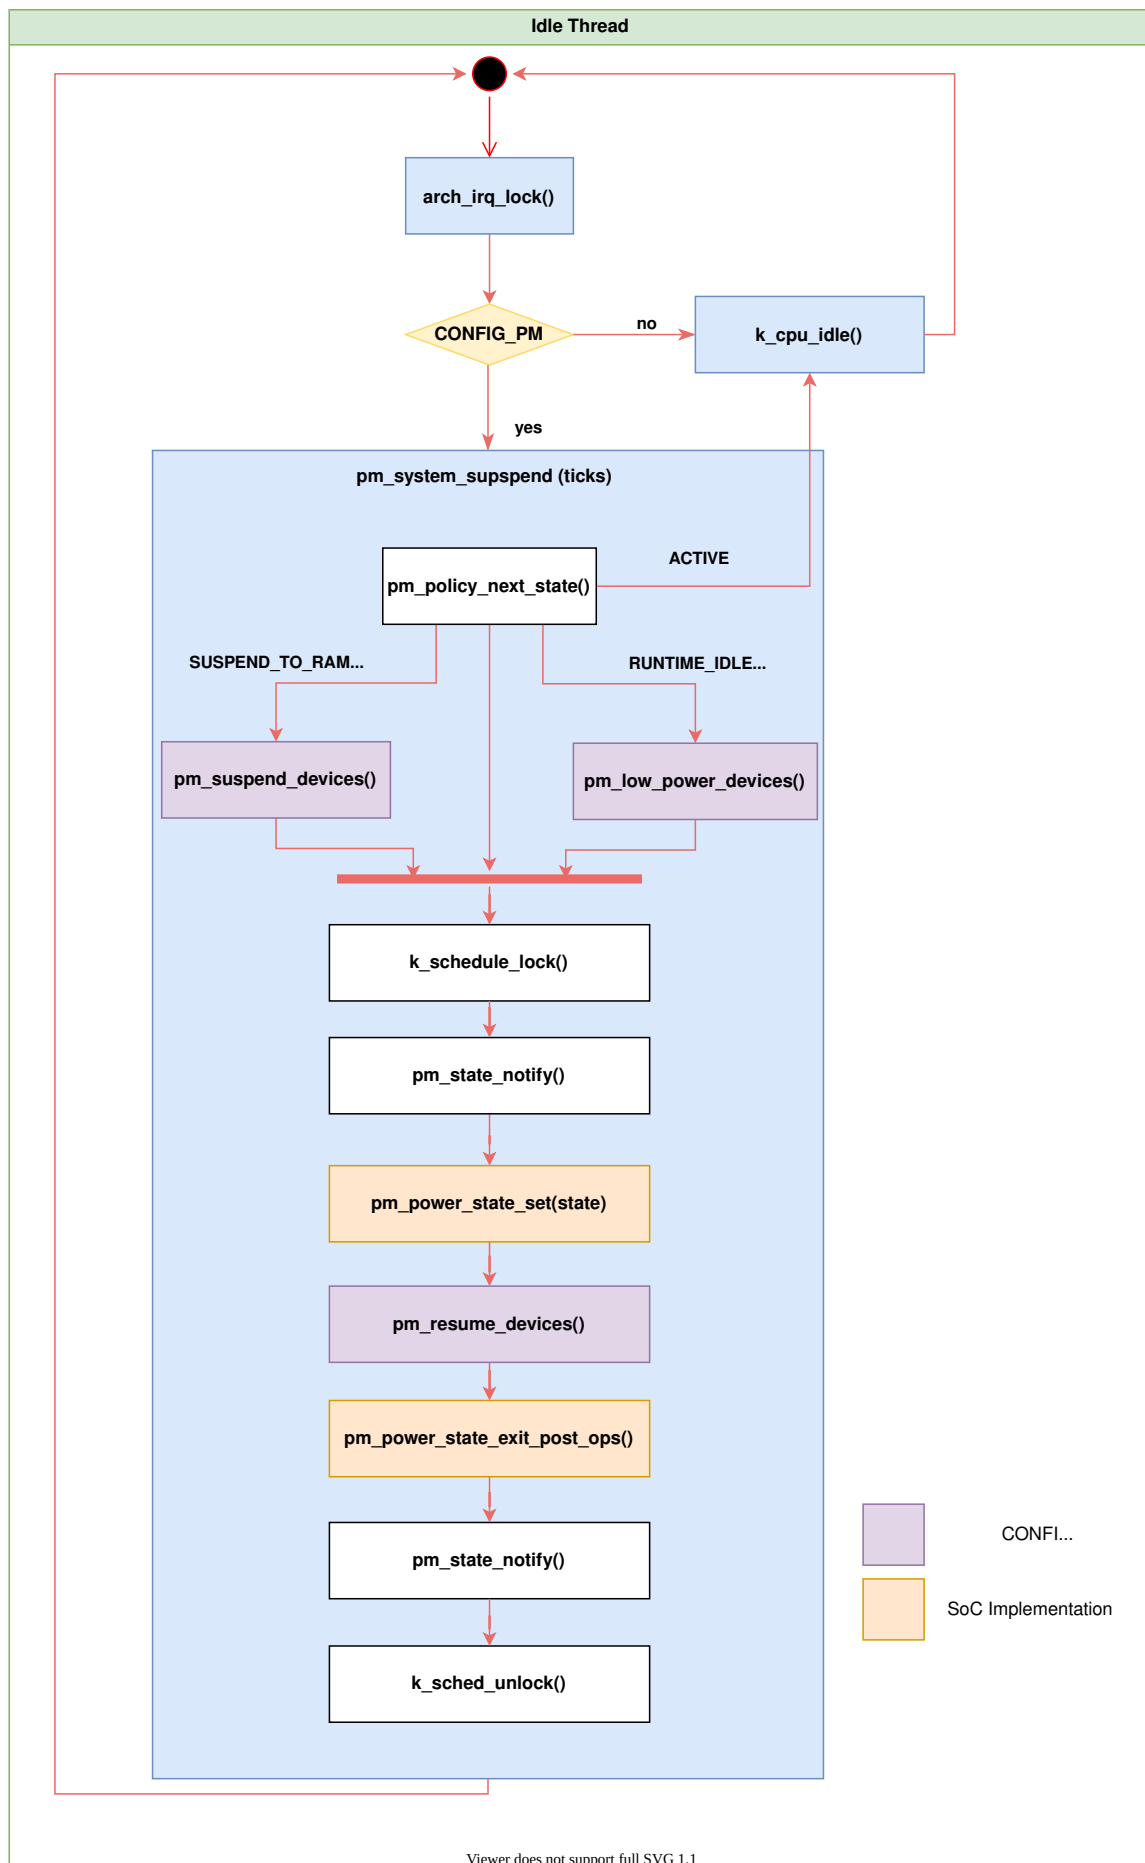

### 7.22.3 System Power Management

The kernel enters the idle state when it has nothing to schedule. If enabled via the **:kconfig: `CONFIG\_PM`** Kconfig option, the Power Management Subsystem can put an idle system in one of the supported power states, based on the selected power management policy and the duration of the idle time allotted by the kernel.

It is an application responsibility to set up a wake up event. A wake up event will typically be an interrupt triggered by one of the SoC peripheral modules such as a SysTick, RTC, counter, or GPIO. Depending on the power mode entered, only some SoC peripheral modules may be active and can be used as a wake up source.

The following diagram describes system power management:

Some handful examples using different power management features:

- [samples/boards/stm32/power\\_mgmt/blinky/](#)
- [samples/boards/nrf/system\\_off/](#)
- [samples/subsys/pm/device\\_pm/](#)
- [tests/subsys/pm/power\\_mgmt/](#)

- [tests/subsys/pm/power\\_state\\_api/](#)

## Power States

The power management subsystem contains a set of states based on power consumption and context retention.

The list of available power states is defined by `pm_state`. In general power states with higher indexes will offer greater power savings and have higher wake latencies. Following is a thorough list of available states:

enumerator `PM_STATE_ACTIVE`

Runtime active state.

The system is fully powered and active.

---

**Note:** This state is correlated with ACPI G0/S0 state

---

enumerator `PM_STATE_RUNTIME_IDLE`

Runtime idle state.

Runtime idle is a system sleep state in which all of the cores enter deepest possible idle state and wait for interrupts, no requirements for the devices, leaving them at the states where they are.

---

**Note:** This state is correlated with ACPI S0ix state

---

enumerator `PM_STATE_SUSPEND_TO_IDLE`

Suspend to idle state.

The system goes through a normal platform suspend where it puts all of the cores in deepest possible idle state and *may* puts peripherals into low-power states. No operating state is lost (ie. the cpu core does not lose execution context), so the system can go back to where it left off easily enough.

---

**Note:** This state is correlated with ACPI S1 state

---

enumerator `PM_STATE_STANDBY`

Standby state.

In addition to putting peripherals into low-power states all non-boot CPUs are powered off. It should allow more energy to be saved relative to suspend to idle, but the resume latency will generally be greater than for that state. But it should be the same state with suspend to idle state on uniprocessor system.

---

**Note:** This state is correlated with ACPI S2 state

---

enumerator PM\_STATE\_SUSPEND\_TO\_RAM

Suspend to ram state.

This state offers significant energy savings by powering off as much of the system as possible, where memory should be placed into the self-refresh mode to retain its contents. The state of devices and CPUs is saved and held in memory, and it may require some boot-strapping code in ROM to resume the system from it.

---

**Note:** This state is correlated with ACPI S3 state

---

enumerator PM\_STATE\_SUSPEND\_TO\_DISK

Suspend to disk state.

This state offers significant energy savings by powering off as much of the system as possible, including the memory. The contents of memory are written to disk or other non-volatile storage, and on resume it's read back into memory with the help of boot-strapping code, restores the system to the same point of execution where it went to suspend to disk.

---

**Note:** This state is correlated with ACPI S4 state

---

enumerator PM\_STATE\_SOFT\_OFF

Soft off state.

This state consumes a minimal amount of power and requires a large latency in order to return to runtime active state. The contents of system(CPU and memory) will not be preserved, so the system will be restarted as if from initial power-up and kernel boot.

---

**Note:** This state is correlated with ACPI G2/S5 state

---

## Power States Constraint

The power management subsystem allows different Zephyr components and applications to set constraints on various power states preventing the system from transitioning into these states. This can be used by devices when executing tasks in background to avoid the system to go to a specific state where it would lose context. Constraints can be set, released and checked using the follow APIs:

**Warning:** doxygenfunction: Cannot find function “pm\_constraint\_set” in doxygen xml output for project “Zephyr” from directory: /build/doc/\_build/latex/doxygen/xml

**Warning:** doxygenfunction: Cannot find function “pm\_constraint\_release” in doxygen xml output for project “Zephyr” from directory: /build/doc/\_build/latex/doxygen/xml

**Warning:** doxygenfunction: Cannot find function “pm\_constraint\_get” in doxygen xml output for project “Zephyr” from directory: /build/doc/\_build/latex/doxygen/xml

## Power Management Policies

The power management subsystem supports the following power management policies:

- Residency based
- Application defined

The policy manager is responsible for informing the power subsystem which power state the system should transition to based on states defined by the platform and possible runtime [constraints](#)

Information about states can be found in the device tree, see [dts/bindings/power/state.yaml](#).

**Residency** The power management system enters the power state which offers the highest power savings, and with a minimum residency value (in device tree, see [dts/bindings/power/state.yaml](#)) less than or equal to the scheduled system idle time duration.

This policy also accounts for the time necessary to become active again. The core logic used by this policy to select the best power state is:

```
if (time_to_next_scheduled_event >= (state.min_residency_us + state.exit_latency)) {
    return state
}
```

**Application** The power management policy is defined by the application which has to implement the following function.

```
struct pm_state_info pm_policy_next_state(int32_t ticks);
```

In this policy the application is free to decide which power state the system should transition to based on the remaining time for the next scheduled timeout.

An example of an application that defines its own policy can be found in [tests/subsys/pm/power\\_mgmt/](#).

### 7.22.4 Device Power Management Infrastructure

The device power management infrastructure consists of interfaces to the [Device Driver Model](#). These APIs send control commands to the device driver to update its power state or to get its current power state.

Zephyr RTOS supports two methods of doing device power management.

- Runtime Device Power Management
- System Power Management

#### Runtime Device Power Management

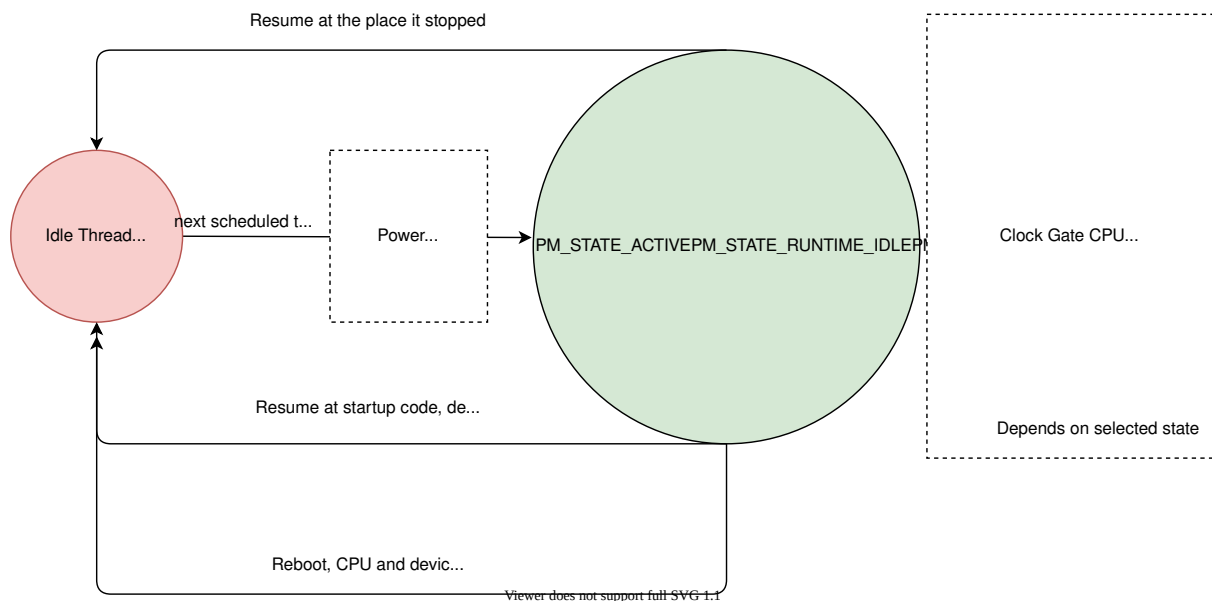

In this method, the application or any component that deals with devices directly and has the best knowledge of their use, performs the device power management. This saves power if some devices that are not in use can be turned off or put in power saving mode. This method allows saving power even when the CPU is active. The components that use the devices need to be power aware and should be able to make decisions related to managing device power.

In this method, the SOC interface can enter CPU or SOC power states quickly when `pm_system_suspend()` gets called. This is because it does not need to spend time doing device power management if the devices are already put in the appropriate power state by the application or component managing the devices.

## System Power Management

In this method device power management is mostly done inside `pm_system_suspend()` along with entering a CPU or SOC power state.

If a decision to enter a lower power state is made, the implementation would enter it only after checking if the devices are not in the middle of a hardware transaction that cannot be interrupted. This method can be used in implementations where the applications and components using devices are not expected to be power aware and do not implement runtime device power management.

This method can also be used to emulate a hardware feature supported by some SOCs which triggers automatic entry to a lower power state when all devices are idle. Refer to [Busy Status Indication](#) to see how to indicate whether a device is busy or idle.

## Device Power Management States

The power management subsystem defines four device states. These states are classified based on the degree of device context that gets lost in those states, kind of operations done to save power, and the impact on the device behavior due to the state transition. Device context includes device registers, clocks, memory etc.

The four device power states:

`PM_DEVICE_STATE_ACTIVE`

Normal operation of the device. All device context is retained.

`PM_DEVICE_STATE_LOW_POWER`

Device context is preserved by the HW and need not be restored by the driver.

`PM_DEVICE_STATE_SUSPENDED`

Most device context is lost by the hardware. Device drivers must save and restore or reinitialize any context lost by the hardware.

`PM_DEVICE_STATE_OFF`

Power has been fully removed from the device. The device context is lost when this state is entered. Need to reinitialize the device when powering it back on.

### Device Power Management Operations

Zephyr RTOS power management subsystem provides a control function interface to device drivers to indicate power management operations to perform. Each device driver defines:

- The device's supported power states.
- The device's supported transitions between power states.
- The device's necessary operations to handle the transition between power states.

The following are some examples of operations that the device driver may perform in transition between power states:

- Save/Restore device states.
- Gate/Un-gate clocks.
- Gate/Un-gate power.
- Mask/Un-mask interrupts.

### Device Model with Power Management Support

Drivers initialize the devices using macros. See [Device Driver Model](#) for details on how these macros are used. Use the `DEVICE_DEFINE` macro to initialize drivers providing power management support via the PM control function. One of the macro parameters is the pointer to the `pm_control` handler function. If the driver doesn't implement any power control operations, it can initialize the corresponding pointer with `NULL`.

### Device Power Management API

The SOC interface and application use these APIs to perform power management operations on the devices.

#### Get Device List

```
size_t z_device_get_all_static(struct device const **device_list);
```

The Zephyr RTOS kernel internally maintains a list of all devices in the system. The SOC interface uses this API to get the device list. The SOC interface can use the list to identify the devices on which to execute power management operations.

---

**Note:** Ensure that the SOC interface does not alter the original list. Since the kernel uses the original list, it must remain unchanged.

---

#### Device Set Power State

```
int pm_device_state_set(const struct device *dev, enum pm_device_state state);
```

Calls the `pm_control()` handler function implemented by the device driver with the provided state.

## Device Get Power State

```
int pm_device_state_get(const struct device *dev, enum pm_device_state *state);
```

## Busy Status Indication

The SOC interface executes some power policies that can turn off power to devices, causing them to lose their state. If the devices are in the middle of some hardware transaction, like writing to flash memory when the power is turned off, then such transactions would be left in an inconsistent state. This infrastructure guards such transactions by indicating to the SOC interface that the device is in the middle of a hardware transaction.

When the `pm_system_suspend()` is called, depending on the power state returned by the policy manager, the system may suspend or put devices in low power if they are not marked as busy.

Here are the APIs used to set, clear, and check the busy status of devices.

### Indicate Busy Status API

```
void device_busy_set(const struct device *busy_dev);
```

Sets a bit corresponding to the device, in a data structure maintained by the kernel, to indicate whether or not it is in the middle of a transaction.

### Clear Busy Status API

```
void device_busy_clear(const struct device *busy_dev);
```

Clears the bit corresponding to the device in a data structure maintained by the kernel to indicate that the device is not in the middle of a transaction.

### Check Busy Status of Single Device API

```
int device_busy_check(const struct device *chk_dev);
```

Checks whether a device is busy. The API returns 0 if the device is not busy.

This API is used by the system power management.

### Check Busy Status of All Devices API

```
int device_any_busy_check(void);
```

Checks if any device is busy. The API returns 0 if no device in the system is busy.

**Wakeup capability** Some devices are capable of waking the system up from a sleep state. When a device has such capability, applications can enable or disable this feature on a device dynamically using `pm_device_wakeup_enable()`.

This property can be set on device declaring the property `wakeup-source` in the device node in device-tree. For example, this devicetree fragment sets the `gpio0` device as a “wakeup” source:

```
gpio0: gpio@40022000 {
    compatible = "ti,cc13xx-cc26xx-gpio";
    reg = <0x40022000 0x400>;
    interrupts = <0 0>;
    status = "disabled";
    label = "GPIO_0";
```

(continues on next page)

(continued from previous page)

```

    gpio-controller;
    wakeup-source;
    #gpio-cells = <2>;
};

```

By default, “wakeup” capable devices do not have this functionality enabled during the device initialization. Applications can enable this functionality later calling `pm_device_wakeup_enable()`.

---

**Note:** This property is **only** used by the system power management to identify devices that should not be suspended. It is responsibility of driver or the application to do any additional configuration required by the device to support it.

---

### 7.22.5 Device Runtime Power Management

The Device Runtime Power Management framework is an Active Power Management mechanism which reduces the overall system Power consumption by suspending the devices which are idle or not being used while the System is active or running.

The framework uses `pm_device_state_set()` API set the device power state accordingly based on the usage count.

The interfaces and APIs provided by the Device Runtime PM are designed to be generic and architecture independent.

#### Device Runtime Power Management API

The Device Drivers use these APIs to perform device runtime power management operations on the devices.

#### Enable Device Runtime Power Management of a Device API

```
void pm_device_enable(const struct device *dev);
```

Enables Runtime Power Management of the device.

#### Disable Device Runtime Power Management of a Device API

```
void pm_device_disable(const struct device *dev);
```

Disables Runtime Power Management of the device.

#### Resume Device asynchronously API

```
int pm_device_get_async(const struct device *dev);
```

Marks the device as being used. This API will asynchronously bring the device to resume state if it was suspended. If the device was already active, it just increments the device usage count. The API returns 0 on success.

Device drivers can monitor this operation to finish calling `pm_device_wait()`.

### Resume Device synchronously API

```
int pm_device_get(const struct device *dev);
```

Marks the device as being used. It will bring up or resume the device if it is in suspended state based on the device usage count. This call is blocked until the device PM state is changed to active. The API returns 0 on success.

### Suspend Device asynchronously API

```
int pm_device_put_async(const struct device *dev);
```

Releases a device. This API asynchronously puts the device to suspend state if not already in suspend state if the usage count of this device reaches 0.

Device drivers can monitor this operation to finish calling `pm_device_wait()`.

### Suspend Device synchronously API

```
int pm_device_put(const struct device *dev);
```

Marks the device as being released. It will put the device to suspended state if it is in active state based on the device usage count. This call is blocked until the device PM state is changed to resume. The API returns 0 on success. This call is blocked until the device is suspended.

## 7.22.6 Power Management Configuration Flags

The Power Management features can be individually enabled and disabled using the following configuration flags.

**:kconfig: `CONFIG\_PM`**

This flag enables the power management subsystem.

**:kconfig: `CONFIG\_PM\_DEVICE`**

This flag is enabled if the SOC interface and the devices support device power management.

**:kconfig: `CONFIG\_PM\_DEVICE\_RUNTIME`**

This flag enables the Runtime Power Management.

## 7.22.7 API Reference

### Power Management Hook Interface

**Warning:** doxyengroup: Cannot find group “power\_management\_hook\_interface” in doxygen xml output for project “Zephyr” from directory: /build/doc/\_build/latex/doxygen/xml

### System Power Management APIs

group system\_power\_management\_api

System Power Management API.

## Defines

```
pm_notifier_register(notifier)
pm_notifier_unregister(notifier)
pm_constraint_set(pm_state)
pm_constraint_release(pm_state)
pm_constraint_get(pm_state)
pm_power_state_set(info)
pm_power_state_exit_post_ops(info)
```

## Variables

```
void (*state_entry)(enum pm_state state)
    Application defined function for doing any target specific operations for power state entry.
```

```
void (*state_exit)(enum pm_state state)
    Application defined function for doing any target specific operations for power state exit.
```

```
struct pm_notifier
```

*#include <pm.h>* Power management notifier struct

This struct contains callbacks that are called when the target enters and exits power states.

As currently implemented the entry callback is invoked when transitioning from PM\_STATE\_ACTIVE to another state, and the exit callback is invoked when transitioning from a non-active state to PM\_STATE\_ACTIVE. This behavior may change in the future.

---

**Note:** These callbacks can be called from the ISR of the event that caused the kernel exit from idling.

---

---

**Note:** It is not allowed to call [pm\\_notifier\\_unregister](#) or [pm\\_notifier\\_register](#) from these callbacks because they are called with the spin locked in those functions.

---

## Public Members

```
void (*state_entry)(enum pm_state state)
    Application defined function for doing any target specific operations for power state entry.
```

```
void (*state_exit)(enum pm_state state)
    Application defined function for doing any target specific operations for power state exit.
```

## Device Power Management APIs

```
group device_power_management_api
    Device Power Management API.
```

## Defines

`device_pm_control_nop`

Alias for legacy use of `device_pm_control_nop`

## Typedefs

`typedef int (*pm_device_control_callback_t)(const struct device *dev, enum pm_device_action action)`

Device power management control function callback.

**Param dev** Device instance.

**Param action** Requested action.

**Retval 0** If successful.

**Retval -ENOTSUP** If the requested action is not supported.

**Retval Errno** Other negative errno on failure.

## Enums

`enum pm_device_state`

Device power states.

*Values:*

enumerator `PM_DEVICE_STATE_ACTIVE`

Device is in active or regular state.

enumerator `PM_DEVICE_STATE_LOW_POWER`

Device is in low power state.

---

**Note:** Device context is preserved.

---

enumerator `PM_DEVICE_STATE_SUSPENDED`

Device is suspended.

---

**Note:** Device context may be lost.

---

enumerator `PM_DEVICE_STATE_OFF`

Device is turned off (power removed).

---

**Note:** Device context is lost.

---

`enum pm_device_flag`

Device PM flags.

*Values:*

enumerator PM\_DEVICE\_FLAG\_BUSY

Indicate if the device is busy or not.

enumerator PM\_DEVICE\_FLAGS\_WS\_CAPABLE

Indicates whether or not the device is capable of waking the system up.

enumerator PM\_DEVICE\_FLAGS\_WS\_ENABLED

Indicates if the device is being used as wakeup source.

enumerator PM\_DEVICE\_FLAG\_TRANSITIONING

Indicates that the device is changing its state

enumerator PM\_DEVICE\_FLAG\_COUNT

Number of flags (internal use only).

enum pm\_device\_action

Device PM actions.

*Values:*

enumerator PM\_DEVICE\_ACTION\_SUSPEND

Suspend.

enumerator PM\_DEVICE\_ACTION\_RESUME

Resume.

enumerator PM\_DEVICE\_ACTION\_TURN\_OFF

Turn off.

enumerator PM\_DEVICE\_ACTION\_FORCE\_SUSPEND

Force suspend.

enumerator PM\_DEVICE\_ACTION\_LOW\_POWER

Low power.

## Functions

const char \*pm\_device\_state\_str(enum *pm\_device\_state* state)

Get name of device PM state.

### Parameters

- state – State id which name should be returned

int pm\_device\_state\_set(const struct *device* \*dev, enum *pm\_device\_state* state)

Set the power state of a device.

This function calls the device PM control callback so that the device does the necessary operations to put the device into the given state.

---

**Note:** Some devices may not support all device power states.

---

**Parameters**

- `dev` – Device instance.
- `state` – Device power state to be set.

**Return values**

- 0 – If successful.
- `-ENOTSUP` – If requested state is not supported.
- `-EALREADY` – If device is already at the requested state.
- `-EBUSY` – If device is changing its state.
- `Errno` – Other negative errno on failure.

`int pm_device_state_get(const struct device *dev, enum pm\_device\_state *state)`  
Obtain the power state of a device.

**Parameters**

- `dev` – Device instance.
- `state` – Pointer where device power state will be stored.

**Return values**

- 0 – If successful.
- `-ENOSYS` – If device does not implement power management.

`static inline void pm_device_busy_set(const struct device *dev)`

`static inline void pm_device_busy_clear(const struct device *dev)`

`static inline bool pm_device_is_any_busy(void)`

`static inline bool pm_device_is_busy(const struct device *dev)`

`static inline void device_busy_set(const struct device *dev)`

`static inline void device_busy_clear(const struct device *dev)`

`static inline int device_any_busy_check(void)`

`static inline int device_busy_check(const struct device *dev)`

`bool pm_device_wakeup_enable(struct device *dev, bool enable)`

Enable a power management wakeup source.

Enable a wakeup source. This will keep the current device active when the system is suspended, allowing it to be used to wake up the system.

**Parameters**

- `dev` – device object to enable.
- `enable` – `true` to enable or `false` to disable

**Return values**

- `true` – if the wakeup source was successfully enabled.
- `false` – if the wakeup source was not successfully enabled.

bool pm\_device\_wakeup\_is\_enabled(const struct *device* \*dev)

Check if a power management wakeup source is enabled.

Checks if a wake up source is enabled.

**Parameters**

- dev – device object to check.

**Return values**

- true – if the wakeup source is enabled.
- false – if the wakeup source is not enabled.

bool pm\_device\_wakeup\_is\_capable(const struct *device* \*dev)

Check if a device is wake up capable.

**Parameters**

- dev – device object to check.

**Return values**

- true – if the device is wake up capable.
- false – if the device is not wake up capable.

struct pm\_device

*#include <device.h>* Device PM info.

**Public Members**

const struct *device* \*dev

Pointer to the device

struct *k\_mutex* lock

Lock to synchronize the get/put operations

bool enable

Device pm enable flag

uint32\_t usage

Device usage count

enum *pm\_device\_state* state

Device power state

struct *k\_work\_delayable* work

Work object for asynchronous calls

struct k\_condvar condvar

Event conditional var to listen to the sync request events

## 7.23 Random Number Generation

The random API subsystem provides random number generation APIs in both cryptographically and non-cryptographically secure instances. Which random API to use is based on the cryptographic requirements of the random number. The non-cryptographic APIs will return random values much faster if non-cryptographic values are needed.

The cryptographically secure random functions shall be compliant to the FIPS 140-2 [?] recommended algorithms. Hardware based random-number generators (RNG) can be used on platforms with appropriate hardware support. Platforms without hardware RNG support shall use the [CTR-DRBG algorithm](#). The algorithm can be provided by [TinyCrypt](#) or [mbedTLS](#) depending on your application performance and resource requirements.

---

**Note:** The CTR-DRBG generator needs an entropy source to establish and maintain the cryptographic security of the PRNG.

---

### 7.23.1 Kconfig Options

These options can be found in the following path [subsys/random/Kconfig](#).

**:kconfig: `CONFIG\_TEST\_RANDOM\_GENERATOR`** For testing, this option permits random number APIs to return values that are not truly random.

The random number generator choice group allows selection of the RNG source function for the system via the RNG\_GENERATOR\_CHOICE choice group. An override of the default value can be specified in the SOC or board .defconfig file by using:

```
choice RNG_GENERATOR_CHOICE
    default XOSHIRO_RANDOM_GENERATOR
endchoice
```

The random number generators available include:

**:kconfig: `CONFIG\_TIMER\_RANDOM\_GENERATOR`** enables number generator based on system timer clock. This number generator is not random and used for testing only.

**:kconfig: `CONFIG\_ENTROPY\_DEVICE\_RANDOM\_GENERATOR`** enables a random number generator that uses the enabled hardware entropy gathering driver to generate random numbers.

**:kconfig: `CONFIG\_XOSHIRO\_RANDOM\_GENERATOR`** enables the Xoshiro128++ pseudo-random number generator, that uses the entropy driver as a seed source.

The CSPRNG\_GENERATOR\_CHOICE choice group provides selection of the cryptographically secure random number generator source function. An override of the default value can be specified in the SOC or board .defconfig file by using:

```
choice CSPRNG_GENERATOR_CHOICE
    default CTR_DRBG_CSPRNG_GENERATOR
endchoice
```

The cryptographically secure random number generators available include:

**:kconfig: `CONFIG\_HARDWARE\_DEVICE\_CS\_GENERATOR`** enables a cryptographically secure random number generator using the hardware random generator driver

**:kconfig: `CONFIG\_CTR\_DRBG\_CSPRNG\_GENERATOR`** enables the CTR-DRBG pseudo-random number generator. The CTR-DRBG is a FIPS140-2 recommended cryptographically secure random number generator.

Personalization data can be provided in addition to the entropy source to make the initialization of the CTR-DRBG as unique as possible.

**:kconfig:** `CONFIG_CS_CTR_DRBG_PERSONALIZATION` CTR-DRBG Initialization Personalization string

### 7.23.2 API Reference

group random\_api

Random Function APIs.

#### Functions

uint32\_t sys\_rand32\_get(void)

Return a 32-bit random value that should pass general randomness tests.

---

**Note:** The random value returned is not a cryptographically secure random number value.

---

**Returns** 32-bit random value.

void sys\_rand\_get(void \*dst, size\_t len)

Fill the destination buffer with random data values that should pass general randomness tests.

---

**Note:** The random values returned are not considered cryptographically secure random number values.

---

#### Parameters

- `dst` – **[out]** destination buffer to fill with random data.
- `len` – size of the destination buffer.

int sys\_csrand\_get(void \*dst, size\_t len)

Fill the destination buffer with cryptographically secure random data values.

---

**Note:** If the random values requested do not need to be cryptographically secure then use [sys\\_rand\\_get\(\)](#) instead.

---

#### Parameters

- `dst` – **[out]** destination buffer to fill.
- `len` – size of the destination buffer.

**Returns** 0 if success, -EIO if entropy reseed error

## 7.24 Resource Management

There are various situations where it's necessary to coordinate resource use at runtime among multiple clients. These include power rails, clocks, other peripherals, and binary device power management. The complexity of properly managing multiple consumers of a device in a multithreaded system, especially when transitions may be asynchronous, suggests that a shared implementation is desirable.

Zephyr provides managers for several coordination policies. These managers are embedded into services that use them for specific functions.

- [On-Off Manager](#)

### 7.24.1 On-Off Manager

An on-off manager supports an arbitrary number of clients of a service which has a binary state. Example applications are power rails, clocks, and binary device power management.

The manager has the following properties:

- The stable states are off, on, and error. The service always begins in the off state. The service may also be in a transition to a given state.
- The core operations are request (add a dependency) and release (remove a dependency). Supporting operations are reset (to clear an error state) and cancel (to reclaim client data from an in-progress transition). The service manages the state based on calls to functions that initiate these operations.
- The service transitions from off to on when first client request is received.
- The service transitions from on to off when last client release is received.
- Each service configuration provides functions that implement the transition from off to on, from on to off, and optionally from an error state to off. Transitions must be invocable from both thread and interrupt context.
- The request and reset operations are asynchronous using [Asynchronous Notification APIs](#). Both operations may be cancelled, but cancellation has no effect on the in-progress transition.
- Requests to turn on may be queued while a transition to off is in progress: when the service has turned off successfully it will be immediately turned on again (where context allows) and waiting clients notified when the start completes.

Requests are reference counted, but not tracked. That means clients are responsible for recording whether their requests were accepted, and for initiating a release only if they have previously successfully completed a request. Improper use of the API can cause an active client to be shut out, and the manager does not maintain a record of specific clients that have been granted a request.

Failures in executing a transition are recorded and inhibit further requests or releases until the manager is reset. Pending requests are notified (and cancelled) when errors are discovered.

Transition operation completion notifications are provided through [Asynchronous Notification APIs](#).

Clients and other components interested in tracking all service state changes, including when a service begins turning off or enters an error state, can be informed of state transitions by registering a monitor with `onoff_monitor_register()`. Notification of changes are provided before issuing completion notifications associated with the new state.

---

**Note:** A generic API may be implemented by multiple drivers where the common case is asynchronous. The on-off client structure may be an appropriate solution for the generic API. Where drivers that can guarantee synchronous context-independent transitions a driver may use [onoff\\_sync\\_service](#) and its supporting API rather than [onoff\\_manager](#), with only a small reduction in functionality (primarily no support for the monitor API).

---

`group resource_mgmt_onoff_apis`

## Defines

ONOFF\_FLAG\_ERROR

Flag indicating an error state.

Error states are cleared using [onoff\\_reset\(\)](#).

ONOFF\_FLAG\_ONOFF

ONOFF\_FLAG\_TRANSITION

ONOFF\_STATE\_MASK

Mask used to isolate bits defining the service state.

Mask a value with this then test for ONOFF\_FLAG\_ERROR to determine whether the machine has an unfixed error, or compare against ONOFF\_STATE\_ON, ONOFF\_STATE\_OFF, ONOFF\_STATE\_TO\_ON, ONOFF\_STATE\_TO\_OFF, or ONOFF\_STATE\_RESETTING.

ONOFF\_STATE\_OFF

Value exposed by ONOFF\_STATE\_MASK when service is off.

ONOFF\_STATE\_ON

Value exposed by ONOFF\_STATE\_MASK when service is on.

ONOFF\_STATE\_ERROR

Value exposed by ONOFF\_STATE\_MASK when the service is in an error state (and not in the process of resetting its state).

ONOFF\_STATE\_TO\_ON

Value exposed by ONOFF\_STATE\_MASK when service is transitioning to on.

ONOFF\_STATE\_TO\_OFF

Value exposed by ONOFF\_STATE\_MASK when service is transitioning to off.

ONOFF\_STATE\_RESETTING

Value exposed by ONOFF\_STATE\_MASK when service is in the process of resetting.

ONOFF\_TRANSITIONS\_INITIALIZER(\_start, \_stop, \_reset)

Initializer for a [onoff\\_transitions](#) object.

### Parameters

- `_start` – a function used to transition from off to on state.
- `_stop` – a function used to transition from on to off state.
- `_reset` – a function used to clear errors and force the service to an off state. Can be null.

ONOFF\_MANAGER\_INITIALIZER(\_transitions)

ONOFF\_CLIENT\_EXTENSION\_POS

Identify region of [sys\\_notify](#) flags available for containing services.

Bits of the flags field of the [sys\\_notify](#) structure contained within the `queued_operation` structure at and above this position may be used by extensions to the [onoff\\_client](#) structure.

These bits are intended for use by containing service implementations to record client-specific information and are subject to other conditions of use specified on the [sys\\_notify](#) API.

## Typedefs

```
typedef void (*onoff_notify_fn)(struct onoff\_manager *mgr, int res)
```

Signature used to notify an on-off manager that a transition has completed.

Functions of this type are passed to service-specific transition functions to be used to report the completion of the operation. The functions may be invoked from any context.

**Param mgr** the manager for which transition was requested.

**Param res** the result of the transition. This shall be non-negative on success, or a negative error code. If an error is indicated the service shall enter an error state.

```
typedef void (*onoff_transition_fn)(struct onoff\_manager *mgr, onoff\_notify\_fn notify)
```

Signature used by service implementations to effect a transition.

Service definitions use two required function pointers of this type to be notified that a transition is required, and a third optional one to reset the service when it is in an error state.

The start function will be called only from the off state.

The stop function will be called only from the on state.

The reset function (where supported) will be called only when [onoff\\_has\\_error\(\)](#) returns true.

---

**Note:** All transitions functions must be isr-ok.

---

**Param mgr** the manager for which transition was requested.

**Param notify** the function to be invoked when the transition has completed. If the transition is synchronous, notify shall be invoked by the implementation before the transition function returns. Otherwise the implementation shall capture this parameter and invoke it when the transition completes.

```
typedef void (*onoff_client_callback)(struct onoff\_manager *mgr, struct onoff\_client *cli, uint32_t state, int res)
```

Signature used to notify an on-off service client of the completion of an operation.

These functions may be invoked from any context including pre-kernel, ISR, or cooperative or pre-emptible threads. Compatible functions must be isr-ok and not sleep.

**Param mgr** the manager for which the operation was initiated. This may be null if the on-off service uses synchronous transitions.

**Param cli** the client structure passed to the function that initiated the operation.

**Param state** the state of the machine at the time of completion, restricted by `ONOFF_STATE_MASK`. `ONOFF_FLAG_ERROR` must be checked independently of whether res is negative as a machine error may indicate that all future operations except [onoff\\_reset\(\)](#) will fail.

**Param res** the result of the operation. Expected values are service-specific, but the value shall be non-negative if the operation succeeded, and negative if the operation failed. If res is negative `ONOFF_FLAG_ERROR` will be set in state, but if res is non-negative `ONOFF_FLAG_ERROR` may still be set in state.

```
typedef void (*onoff_monitor_callback)(struct onoff_manager *mgr, struct onoff_monitor *mon,
uint32_t state, int res)
```

Signature used to notify a monitor of an onoff service of errors or completion of a state transition.

This is similar to `onoff_client_callback` but provides information about all transitions, not just ones associated with a specific client. Monitor callbacks are invoked before any completion notifications associated with the state change are made.

These functions may be invoked from any context including pre-kernel, ISR, or cooperative or pre-emptible threads. Compatible functions must be `isr-ok` and not sleep.

The callback is permitted to unregister itself from the manager, but must not register or unregister any other monitors.

**Param mgr** the manager for which a transition has completed.

**Param mon** the monitor instance through which this notification arrived.

**Param state** the state of the machine at the time of completion, restricted by `ONOFF_STATE_MASK`. All valid states may be observed.

**Param res** the result of the operation. Expected values are service- and state-specific, but the value shall be non-negative if the operation succeeded, and negative if the operation failed.

## Functions

```
int onoff_manager_init(struct onoff_manager *mgr, const struct onoff_transitions *transitions)
```

Initialize an on-off service to off state.

This function must be invoked exactly once per service instance, by the infrastructure that provides the service, and before any other on-off service API is invoked on the service.

This function should never be invoked by clients of an on-off service.

### Parameters

- `mgr` – the manager definition object to be initialized.
- `transitions` – pointer to a structure providing transition functions. The referenced object must persist as long as the manager can be referenced.

### Return values

- 0 – on success
- `-EINVAL` – if start, stop, or flags are invalid

```
static inline bool onoff_has_error(const struct onoff_manager *mgr)
```

Test whether an on-off service has recorded an error.

This function can be used to determine whether the service has recorded an error. Errors may be cleared by invoking `onoff_reset()`.

This is an unlocked convenience function suitable for use only when it is known that no other process might invoke an operation that transitions the service between an error and non-error state.

**Returns** true if and only if the service has an uncleared error.

```
int onoff_request(struct onoff_manager *mgr, struct onoff_client *cli)
```

Request a reservation to use an on-off service.

The return value indicates the success or failure of an attempt to initiate an operation to request the resource be made available. If initiation of the operation succeeds the result of

the request operation is provided through the configured client notification method, possibly before this call returns.

Note that the call to this function may succeed in a case where the actual request fails. Always check the operation completion result.

#### Parameters

- `mgr` – the manager that will be used.
- `cli` – a non-null pointer to client state providing instructions on synchronous expectations and how to notify the client when the request completes. Behavior is undefined if client passes a pointer object associated with an incomplete service operation.

#### Return values

- `non-negative` – the observed state of the machine at the time the request was processed, if successful.
- `-EIO` – if service has recorded an an error.
- `-EINVAL` – if the parameters are invalid.
- `-EAGAIN` – if the reference count would overflow.

```
int onoff_release(struct onoff\_manager *mgr)
```

Release a reserved use of an on-off service.

This synchronously releases the caller's previous request. If the last request is released the manager will initiate a transition to off, which can be observed by registering an [onoff\\_monitor](#).

---

**Note:** Behavior is undefined if this is not paired with a preceding [onoff\\_request\(\)](#) call that completed successfully.

---

#### Parameters

- `mgr` – the manager for which a request was successful.

#### Return values

- `non-negative` – the observed state (`ONOFF_STATE_ON`) of the machine at the time of the release, if the release succeeds.
- `-EIO` – if service has recorded an an error.
- `-ENOTSUP` – if the machine is not in a state that permits release.

```
int onoff_cancel(struct onoff\_manager *mgr, struct onoff\_client *cli)
```

Attempt to cancel an in-progress client operation.

It may be that a client has initiated an operation but needs to shut down before the operation has completed. For example, when a request was made and the need is no longer present.

Cancelling is supported only for [onoff\\_request\(\)](#) and [onoff\\_reset\(\)](#) operations, and is a synchronous operation. Be aware that any transition that was initiated on behalf of the client will continue to progress to completion: it is only notification of transition completion that may be eliminated. If there are no active requests when a transition to on completes the manager will initiate a transition to off.

Client notification does not occur for cancelled operations.

#### Parameters

- `mgr` – the manager for which an operation is to be cancelled.

- `cli` – a pointer to the same client state that was provided when the operation to be cancelled was issued.

#### Return values

- `non-negative` – the observed state of the machine at the time of the cancellation, if the cancellation succeeds. On successful cancellation ownership of `*cli` reverts to the client.
- `-EINVAL` – if the parameters are invalid.
- `-EALREADY` – if `cli` was not a record of an uncompleted notification at the time the cancellation was processed. This likely indicates that the operation and client notification had already completed.

static inline int onoff\_cancel\_or\_release(struct [onoff\\_manager](#) \*mgr, struct [onoff\\_client](#) \*cli)

Helper function to safely cancel a request.

Some applications may want to issue requests on an asynchronous event (such as connection to a USB bus) and to release on a paired event (such as loss of connection to a USB bus). Applications cannot precisely determine that an in-progress request is still pending without using [onoff\\_monitor](#) and carefully avoiding race conditions.

This function is a helper that attempts to cancel the operation and issues a release if cancellation fails because the request was completed. This synchronously ensures that ownership of the client data reverts to the client so is available for a future request.

#### Parameters

- `mgr` – the manager for which an operation is to be cancelled.
- `cli` – a pointer to the same client state that was provided when [onoff\\_request\(\)](#) was invoked. Behavior is undefined if this is a pointer to client data associated with an [onoff\\_reset\(\)](#) request.

#### Return values

- `ONOFF_STATE_TO_ON` – if the cancellation occurred before the transition completed.
- `ONOFF_STATE_ON` – if the cancellation occurred after the transition completed.
- `-EINVAL` – if the parameters are invalid.
- `negative` – other errors produced by [onoff\\_release\(\)](#).

int onoff\_reset(struct [onoff\\_manager](#) \*mgr, struct [onoff\\_client](#) \*cli)

Clear errors on an on-off service and reset it to its off state.

A service can only be reset when it is in an error state as indicated by [onoff\\_has\\_error\(\)](#).

The return value indicates the success or failure of an attempt to initiate an operation to reset the resource. If initiation of the operation succeeds the result of the reset operation itself is provided through the configured client notification method, possibly before this call returns. Multiple clients may request a reset; all are notified when it is complete.

Note that the call to this function may succeed in a case where the actual reset fails. Always check the operation completion result.

---

**Note:** Due to the conditions on state transition all incomplete asynchronous operations will have been informed of the error when it occurred. There need be no concern about dangling requests left after a reset completes.

---

#### Parameters

- `mgr` – the manager to be reset.

- `cli` – pointer to client state, including instructions on how to notify the client when reset completes. Behavior is undefined if `cli` references an object associated with an incomplete service operation.

**Return values**

- `non-negative` – the observed state of the machine at the time of the reset, if the reset succeeds.
- `-ENOTSUP` – if reset is not supported by the service.
- `-EINVAL` – if the parameters are invalid.
- `-EALREADY` – if the service does not have a recorded error.

```
int onoff_monitor_register(struct onoff_manager *mgr, struct onoff_monitor *mon)
```

Add a monitor of state changes for a manager.

**Parameters**

- `mgr` – the manager for which a state changes are to be monitored.
- `mon` – a linkable node providing a non-null callback to be invoked on state changes.

**Returns** non-negative on successful addition, or a negative error code.

```
int onoff_monitor_unregister(struct onoff_manager *mgr, struct onoff_monitor *mon)
```

Remove a monitor of state changes from a manager.

**Parameters**

- `mgr` – the manager for which a state changes are to be monitored.
- `mon` – a linkable node providing the callback to be invoked on state changes.

**Returns** non-negative on successful removal, or a negative error code.

```
int onoff_sync_lock(struct onoff_sync_service *srv, k_spinlock_key_t *keyp)
```

Lock a synchronous onoff service and provide its state.

---

**Note:** If an error state is returned it is the caller's responsibility to decide whether to preserve it (finalize with the same error state) or clear the error (finalize with a non-error result).

---

**Parameters**

- `srv` – pointer to the synchronous service state.
- `keyp` – pointer to where the lock key should be stored

**Returns** negative if the service is in an error state, otherwise the number of active requests at the time the lock was taken. The lock is held on return regardless of whether a negative state is returned.

```
int onoff_sync_finalize(struct onoff_sync_service *srv, k_spinlock_key_t key, struct onoff_client *cli, int res, bool on)
```

Process the completion of a transition in a synchronous service and release lock.

This function updates the service state on the `res` and on parameters then releases the lock. If `cli` is not null it finalizes the client notification using `res`.

If the service was in an error state when locked, and `res` is non-negative when finalized, the count is reset to zero before completing finalization.

**Parameters**

- `srv` – pointer to the synchronous service state

- `key` – the key returned by the preceding invocation of `onoff_sync_lock()`.
- `cli` – pointer to the onoff client through which completion information is returned. If a null pointer is passed only the state of the service is updated. For compatibility with the behavior of callbacks used with the manager API `cli` must be null when `on` is false (the manager does not support callbacks when turning off devices).
- `res` – the result of the transition. A negative value places the service into an error state. A non-negative value increments or decrements the reference count as specified by `on`.
- `on` – Only when `res` is non-negative, the service reference count will be incremented if `on` is true, and decremented if `on` is false.

**Returns** negative if the service is left or put into an error state, otherwise the number of active requests at the time the lock was released.

struct onoff\_transitions

`#include <onoff.h>` On-off service transition functions.

struct onoff\_manager

`#include <onoff.h>` State associated with an on-off manager.

No fields in this structure are intended for use by service providers or clients. The state is to be initialized once, using `onoff_manager_init()`, when the service provider is initialized. In case of error it may be reset through the `onoff_reset()` API.

struct onoff\_client

`#include <onoff.h>` State associated with a client of an on-off service.

Objects of this type are allocated by a client, which is responsible for zero-initializing the node field and invoking the appropriate `sys_notify` init function to configure notification.

Control of the object content transfers to the service provider when a pointer to the object is passed to any on-off manager function. While the service provider controls the object the client must not change any object fields. Control reverts to the client concurrent with release of the owned `sys_notify` structure, or when indicated by an `onoff_cancel()` return value.

After control has reverted to the client the notify field must be reinitialized for the next operation.

## Public Members

struct `sys_notify` notify

Notification configuration.

struct onoff\_monitor

`#include <onoff.h>` Registration state for notifications of onoff service transitions.

Any given `onoff_monitor` structure can be associated with at most one `onoff_manager` instance.

## Public Members

`onoff_monitor_callback` callback

Callback to be invoked on state change.

This must not be null.

```
struct onoff_sync_service
```

*#include <onoff.h>* State used when a driver uses the on-off service API for synchronous operations.

This is useful when a subsystem API uses the on-off API to support asynchronous operations but the transitions required by a particular driver are isr-ok and not sleep. It serves as a substitute for [onoff\\_manager](#), with locking and persisted state updates supported by [onoff\\_sync\\_lock\(\)](#) and [onoff\\_sync\\_finalize\(\)](#).

## 7.25 Shell

- [Overview](#)
  - [Connecting to Segger RTT via TCP \(on macOS, for example\)](#)
- [Commands](#)
  - [Creating commands](#)
  - [Dictionary commands](#)
  - [Commands execution](#)
  - [Built-in commands](#)
- [Tab Feature](#)
- [History Feature](#)
- [Wildcards Feature](#)
- [Meta Keys Feature](#)
- [Getopt Feature](#)
- [Obscured Input Feature](#)
- [Shell Logger Backend Feature](#)
- [Usage](#)
- [API Reference](#)

### 7.25.1 Overview

This module allows you to create and handle a shell with a user-defined command set. You can use it in examples where more than simple button or LED user interaction is required. This module is a Unix-like shell with these features:

- Support for multiple instances.
- Advanced cooperation with the [Logging](#).
- Support for static and dynamic commands.
- Support for dictionary commands.
- Smart command completion with the Tab key.
- Built-in commands: `clear`, `shell`, `colors`, `echo`, `history` and `resize`.
- Viewing recently executed commands using keys: `↑` `↓` or meta keys.
- Text edition using keys: `←`, `→`, `Backspace`, `Delete`, `End`, `Home`, `Insert`.

- Support for ANSI escape codes: VT100 and ESC[n~ for cursor control and color printing.
- Support for editing multiline commands.
- Built-in handler to display help for the commands.
- Support for wildcards: \* and ?.
- Support for meta keys.
- Support for getopt.
- Kconfig configuration to optimize memory usage.

---

**Note:** Some of these features have a significant impact on RAM and flash usage, but many can be disabled when not needed. To default to options which favor reduced RAM and flash requirements instead of features, you should enable `:kconfig: `CONFIG_SHELL_MINIMAL`` and selectively enable just the features you want.

---

The module can be connected to any transport for command input and output. At this point, the following transport layers are implemented:

- Segger RTT
- SMP
- Telnet
- UART
- USB
- DUMMY - not a physical transport layer.

### Connecting to Segger RTT via TCP (on macOS, for example)

On macOS JLinkRTTClient won't let you enter input. Instead, please use following procedure:

- Open up a first Terminal window and enter:

```
JLinkRTTLogger -Device NRF52840_XXAA -RTTChannel 1 -if SWD -Speed 4000 ~/rtt.log
```

(change device if required)

- Open up a second Terminal window and enter:

```
nc localhost 19021
```

- Now you should have a network connection to RTT that will let you enter input to the shell.

## 7.25.2 Commands

Shell commands are organized in a tree structure and grouped into the following types:

- Root command (level 0): Gathered and alphabetically sorted in a dedicated memory section.
- Static subcommand (level > 0): Number and syntax must be known during compile time. Created in the software module.
- Dynamic subcommand (level > 0): Number and syntax does not need to be known during compile time. Created in the software module.

## Creating commands

Use the following macros for adding shell commands:

- `SHELL_CMD_REGISTER` - Create root command. All root commands must have different name.
- `SHELL_COND_CMD_REGISTER` - Conditionally (if compile time flag is set) create root command. All root commands must have different name.
- `SHELL_CMD_ARG_REGISTER` - Create root command with arguments. All root commands must have different name.
- `SHELL_COND_CMD_ARG_REGISTER` - Conditionally (if compile time flag is set) create root command with arguments. All root commands must have different name.
- `SHELL_CMD` - Initialize a command.
- `SHELL_COND_CMD` - Initialize a command if compile time flag is set.
- `SHELL_EXPR_CMD` - Initialize a command if compile time expression is non-zero.
- `SHELL_CMD_ARG` - Initialize a command with arguments.
- `SHELL_COND_CMD_ARG` - Initialize a command with arguments if compile time flag is set.
- `SHELL_EXPR_CMD_ARG` - Initialize a command with arguments if compile time expression is non-zero.
- `SHELL_STATIC_SUBCMD_SET_CREATE` - Create a static subcommands array.
- `SHELL_SUBCMD_DICT_SET_CREATE` - Create a dictionary subcommands array.
- `SHELL_DYNAMIC_CMD_CREATE` - Create a dynamic subcommands array.

Commands can be created in any file in the system that includes `include/shell/shell.h`. All created commands are available for all shell instances.

**Static commands** Example code demonstrating how to create a root command with static subcommands.

```
/* Creating subcommands (level 1 command) array for command "demo". */
SHELL_STATIC_SUBCMD_SET_CREATE(sub_demo,
    SHELL_CMD(params, NULL, "Print params command.",
                                     cmd_demo_params),
    SHELL_CMD(ping, NULL, "Ping command.", cmd_demo_ping),
    SHELL_SUBCMD_SET_END
);
/* Creating root (level 0) command "demo" */
SHELL_CMD_REGISTER(demo, &sub_demo, "Demo commands", NULL);
```

Example implementation can be found under following location: `samples/subsys/shell/shell_module/src/main.c`.

## Dictionary commands

This is a special kind of static commands. Dictionary commands can be used every time you want to use a pair: (string <-> corresponding data) in a command handler. The string is usually a verbal description of a given data. The idea is to use the string as a command syntax that can be prompted by the shell and corresponding data can be used to process the command.

Let's use an example. Suppose you created a command to set an ADC gain. It is a perfect place where a dictionary can be used. The dictionary would be a set of pairs: (string: gain\_value, int: value) where int value could be used with the ADC driver API.

Abstract code for this task would look like this:

```
static int gain_cmd_handler(const struct shell *shell,
                           size_t argc, char **argv, void *data)
{
    int gain;

    /* data is a value corresponding to called command syntax */
    gain = (int)data;
    adc_set_gain(gain);

    shell_print(shell, "ADC gain set to: %s\n"
                  "Value send to ADC driver: %d",
                  argv[0],
                  gain);

    return 0;
}

SHELL_SUBCMD_DICT_SET_CREATE(sub_gain, gain_cmd_handler,
                             (gain_1, 1), (gain_2, 2), (gain_1_2, 3), (gain_1_4, 4)
);
SHELL_CMD_REGISTER(gain, &sub_gain, "Set ADC gain", NULL);
```

This is how it would look like in the shell:

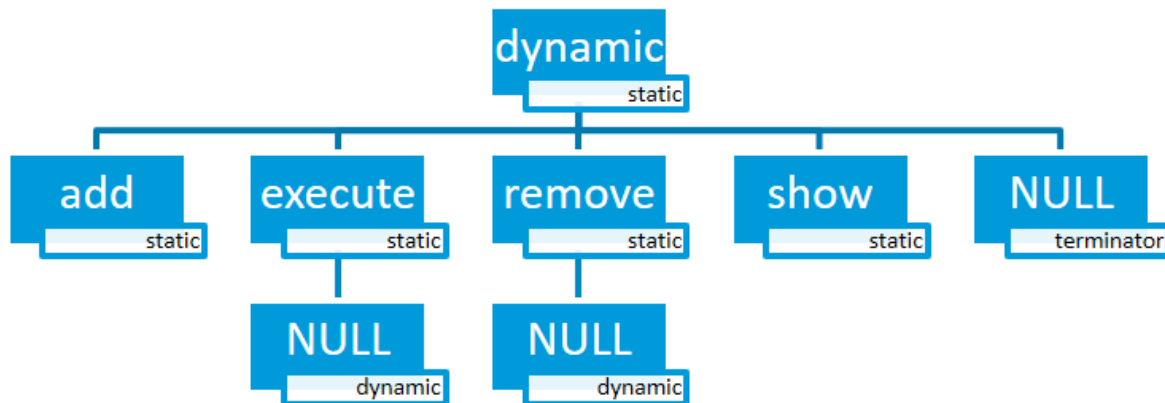

```
uart:~$ gain ga
   gain_1   gain_2   gain_1_2   gain_1_4
uart:~$ gain gain_1
ADC gain set to: gain_1
Value send to ADC driver: 1
uart:~$ gain gain_2
ADC gain set to: gain_2
Value send to ADC driver: 2
uart:~$ gain gain_1_2
ADC gain set to: gain_1_2
Value send to ADC driver: 3
uart:~$ gain gain_1_4
ADC gain set to: gain_1_4
Value send to ADC driver: 4
uart:~$
```

**Dynamic commands** Example code demonstrating how to create a root command with static and dynamic subcommands. At the beginning dynamic command list is empty. New commands can be added by typing:

```
dynamic add <new_dynamic_command>
```

Newly added commands can be prompted or autocompleted with the Tab key.

```

/* Buffer for 10 dynamic commands */
static char dynamic_cmd_buffer[10][50];

/* commands counter */
static uint8_t dynamic_cmd_cnt;

/* Function returning command dynamically created
 * in dynamic_cmd_buffer.
 */
static void dynamic_cmd_get(size_t idx,
                           struct shell_static_entry *entry)
{
    if (idx < dynamic_cmd_cnt) {
        entry->syntax = dynamic_cmd_buffer[idx];
        entry->handler = NULL;
        entry->subcmd = NULL;
        entry->help = "Show dynamic command name.";
    } else {
        /* if there are no more dynamic commands available
         * syntax must be set to NULL.
         */
        entry->syntax = NULL;
    }
}

SHELL_DYNAMIC_CMD_CREATE(m_sub_dynamic_set, dynamic_cmd_get);
SHELL_STATIC_SUBCMD_SET_CREATE(m_sub_dynamic,
    SHELL_CMD(add, NULL, "Add new command to dynamic_cmd_buffer and"
              " sort them alphabetically.",
              cmd_dynamic_add),
    SHELL_CMD(execute, &m_sub_dynamic_set,
              "Execute a command.", cmd_dynamic_execute),
    SHELL_CMD(remove, &m_sub_dynamic_set,
              "Remove a command from dynamic_cmd_buffer.",
              cmd_dynamic_remove),
    SHELL_CMD(show, NULL,
              "Show all commands in dynamic_cmd_buffer.",
              cmd_dynamic_show),

```

(continues on next page)

(continued from previous page)

```

        SHELL_SUBCMD_SET_END
    );
    SHELL_CMD_REGISTER(dynamic, &m_sub_dynamic,
        "Demonstrate dynamic command usage.", cmd_dynamic);

```

Example implementation can be found under following location: [samples/subsys/shell/shell\\_module/src/dynamic\\_cmd.c](#).

## Commands execution

Each command or subcommand may have a handler. The shell executes the handler that is found deepest in the command tree and further subcommands (without a handler) are passed as arguments. Characters within parentheses are treated as one argument. If shell won't find a handler it will display an error message.

Commands can be also executed from a user application using any active backend and a function `shell_execute_cmd()`, as shown in this example:

```

void main(void)
{
    /* Below code will execute "clear" command on a DUMMY backend */
    shell_execute_cmd(NULL, "clear");

    /* Below code will execute "shell colors off" command on
     * an UART backend
     */
    shell_execute_cmd(shell_backend_uart_get_ptr(),
        "shell colors off");
}

```

Enable the DUMMY backend by setting the Kconfig `:kconfig: `CONFIG_SHELL_BACKEND_DUMMY`` option.

**Command handler** Simple command handler implementation:

```

static int cmd_handler(const struct shell *shell, size_t argc,
    char **argv)
{
    ARG_UNUSED(argc);
    ARG_UNUSED(argv);

    shell_fprintf(shell, SHELL_INFO, "Print info message\n");

    shell_print(shell, "Print simple text.");

    shell_warn(shell, "Print warning text.");

    shell_error(shell, "Print error text.");

    return 0;
}

```

Function `shell_fprintf()` or the shell print macros: `shell_print`, `shell_info`, `shell_warn` and `shell_error` can be used from the command handler or from threads, but not from an interrupt context. Instead, interrupt handlers should use [Logging](#) for printing.

**Command help** Every user-defined command or subcommand can have its own help description. The help for commands and subcommands can be created with respective macros: `SHELL_CMD_REGISTER`, `SHELL_CMD_ARG_REGISTER`, `SHELL_CMD`, and `SHELL_CMD_ARG`.

Shell prints this help message when you call a command or subcommand with `-h` or `--help` parameter.

**Parent commands** In the subcommand handler, you can access both the parameters passed to commands or the parent commands, depending on how you index `argv`.

- When indexing `argv` with positive numbers, you can access the parameters.
- When indexing `argv` with negative numbers, you can access the parent commands.
- The subcommand to which the handler belongs has the `argv` index of 0.

```
static int cmd_handler(const struct shell *shell, size_t argc,
                      char **argv)
{
    ARG_UNUSED(argc);

    /* If it is a subcommand handler parent command syntax
     * can be found using argv[-1].
     */
    shell_print(shell, "This command has a parent command: %s",
                argv[-1]);

    /* Print this command syntax */
    shell_print(shell, "This command syntax is: %s", argv[0]);

    /* Print first argument */
    shell_print(shell, "%s", argv[1]);

    return 0;
}
```

## Built-in commands

These commands are activated by `:kconfig: `CONFIG_SHELL_CMDS`` set to y.

- `clear` - Clears the screen.
- `history` - Shows the recently entered commands.
- `resize` - Must be executed when terminal width is different than 80 characters or after each change of terminal width. It ensures proper multiline text display and `←`, `→`, End, Home keys handling. Currently this command works only with UART flow control switched on. It can be also called with a subcommand:
  - `default` - Shell will send terminal width = 80 to the terminal and assume successful delivery.

These command needs extra activation: `:kconfig: `CONFIG_SHELL_CMDS_RESIZE`` set to y.

- `select` - It can be used to set new root command. Exit to main command tree is with `alt+r`. This command needs extra activation: `:kconfig: `CONFIG_SHELL_CMDS_SELECT`` set to y.
- `shell` - Root command with useful shell-related subcommands like:
  - `echo` - Toggles shell echo.
  - `colors` - Toggles colored syntax. This might be helpful in case of Bluetooth shell to limit the amount of transferred bytes.
  - `stats` - Shows shell statistics.

### 7.25.3 Tab Feature

The Tab button can be used to suggest commands or subcommands. This feature is enabled by `:kconfig:CONFIG_SHELL_TAB` set to y. It can also be used for partial or complete auto-completion of commands. This feature is activated by `:kconfig:CONFIG_SHELL_TAB_AUTOCOMPLETION` set to y. When user starts writing a command and presses the Tab button then the shell will do one of 3 possible things:

- Autocomplete the command.
- Prompts available commands and if possible partly completes the command.
- Will not do anything if there are no available or matching commands.

```
uart:~$ log
  backend      disable      enable      go      halt
  list_backends status
uart:~$ log enable
  dbg  err  inf  none  wrn
uart:~$ log enable err
  app      app_test      log      os
  shell.shell_uart shell_uart
uart:~$ log enable err shell
  shell.shell_uart shell_uart
uart:~$ log enable err shell
```

### 7.25.4 History Feature

This feature enables commands history in the shell. It is activated by: `:kconfig:CONFIG_SHELL_HISTORY` set to y. History can be accessed using keys: `↑ ↓` or `Ctrl + n` and `Ctrl + p` if meta keys are active. Number of commands that can be stored depends on size of `:kconfig:CONFIG_SHELL_HISTORY_BUFFER` parameter.

### 7.25.5 Wildcards Feature

The shell module can handle wildcards. Wildcards are interpreted correctly when expanded command and its subcommands do not have a handler. For example, if you want to set logging level to `err` for the `app` and `app_test` modules you can execute the following command:

```
log enable err a*
```

```
uart:~$ log status
module_name      | current | built-in
-----
app               | inf     | inf
app test         | inf     | inf
shell_uart_shell | inf     | inf
uart:~$ log enable err a*
uart:~$ log status
module_name      | current | built-in
-----
app               | err     | inf
app test         | err     | inf
shell_uart_shell | inf     | inf
uart:~$
```

This feature is activated by `:kconfig: `CONFIG_SHELL_WILDCARD`` set to `y`.

### 7.25.6 Meta Keys Feature

The shell module supports the following meta keys:

Table 7: Implemented meta keys

Meta keys	Action
Ctrl + a	Moves the cursor to the beginning of the line.
Ctrl + b	Moves the cursor backward one character.
Ctrl + c	Preserves the last command on the screen and starts a new command in a new line.
Ctrl + d	Deletes the character under the cursor.
Ctrl + e	Moves the cursor to the end of the line.
Ctrl + f	Moves the cursor forward one character.
Ctrl + k	Deletes from the cursor to the end of the line.
Ctrl + l	Clears the screen and leaves the currently typed command at the top of the screen.
Ctrl + n	Moves in history to next entry.
Ctrl + p	Moves in history to previous entry.
Ctrl + u	Clears the currently typed command.
Ctrl + w	Removes the word or part of the word to the left of the cursor. Words separated by period instead of space are treated as one word.
Alt + b	Moves the cursor backward one word.
Alt + f	Moves the cursor forward one word.

This feature is activated by `:kconfig: `CONFIG_SHELL_METAKEYS`` set to `y`.

### 7.25.7 Getopt Feature

Some shell users apart from subcommands might need to use options as well. the arguments string, looking for supported options. Typically, this task is accomplished by the `getopt` function.

For this purpose shell supports the `getopt` library available in the FreeBSD project. I was modified so that it can be used by all instances of the shell at the same time, hence its call requires one more parameter.

An example usage:

```
while ((char c = shell_getopt(shell, argc, argv, "abhc:")) != -1) {  
    /* some code */  
}
```

This module is activated by `:kconfig: `CONFIG_SHELL_GETOPT`` set to `y`.

### 7.25.8 Obscured Input Feature

With the obscured input feature, the shell can be used for implementing a login prompt or other user interaction whereby the characters the user types should not be revealed on screen, such as when entering a password.

Once the obscured input has been accepted, it is normally desired to return the shell to normal operation. Such runtime control is possible with the `shell_obscure_set` function.

An example of login and logout commands using this feature is located in `samples/subsys/shell/shell_module/src/main.c` and the config file `samples/subsys/shell/shell_module/prj_login.conf`.

This feature is activated upon startup by `:kconfig: `CONFIG_SHELL_START_OBSCURED`` set to `y`. With this set either way, the option can still be controlled later at runtime. `:kconfig: `CONFIG_SHELL_CMDS_SELECT`` is useful to prevent entry of any other command besides a login command, by means of the `shell_set_root_cmd` function. Likewise, `:kconfig: `CONFIG_SHELL_PROMPT_UART`` allows you to set the prompt upon startup, but it can be changed later with the `shell_prompt_change` function.

### 7.25.9 Shell Logger Backend Feature

Shell instance can act as the *Logging* backend. Shell ensures that log messages are correctly multiplexed with shell output. Log messages from logger thread are enqueued and processed in the shell thread. Logger thread will block for configurable amount of time if queue is full, blocking logger thread context for that time. Oldest log message is removed from the queue after timeout and new message is enqueued. Use the `shell stats show` command to retrieve number of log messages dropped by the shell instance. Log queue size and timeout are `SHELL_DEFINE` arguments.

This feature is activated by: `:kconfig: `CONFIG_SHELL_LOG_BACKEND`` set to `y`.

**Warning:** Enqueuing timeout must be set carefully when multiple backends are used in the system. The shell instance could have a slow transport or could block, for example, by a UART with hardware flow control. If timeout is set too high, the logger thread could be blocked and impact other logger backends.

**Warning:** As the shell is a complex logger backend, it can not output logs if the application crashes before the shell thread is running. In this situation, you can enable one of the simple logging backends instead, such as UART (`:kconfig: `CONFIG_LOG_BACKEND_UART``) or RTT (`:kconfig: `CONFIG_LOG_BACKEND_RTT``), which are available earlier during system initialization.

### 7.25.10 Usage

To create a new shell instance user needs to activate requested backend using `menuconfig`.

The following code shows a simple use case of this library:

```
void main(void)
{
}

static int cmd_demo_ping(const struct shell *shell, size_t argc,
                        char **argv)
{
    ARG_UNUSED(argc);
    ARG_UNUSED(argv);

    shell_print(shell, "pong");
    return 0;
}

static int cmd_demo_params(const struct shell *shell, size_t argc,
                          char **argv)
{
    int cnt;
```

(continues on next page)

(continued from previous page)

```
    shell_print(shell, "argc = %d", argc);
    for (cnt = 0; cnt < argc; cnt++) {
        shell_print(shell, "  argv[%d] = %s", cnt, argv[cnt]);
    }
    return 0;
}

/* Creating subcommands (level 1 command) array for command "demo". */
SHELL_STATIC_SUBCMD_SET_CREATE(sub_demo,
    SHELL_CMD(params, NULL, "Print params command.",
                                   cmd_demo_params),
    SHELL_CMD(ping, NULL, "Ping command.", cmd_demo_ping),
    SHELL_SUBCMD_SET_END
);
/* Creating root (level 0) command "demo" without a handler */
SHELL_CMD_REGISTER(demo, &sub_demo, "Demo commands", NULL);

/* Creating root (level 0) command "version" */
SHELL_CMD_REGISTER(version, NULL, "Show kernel version", cmd_version);
```

Users may use the Tab key to complete a command/subcommand or to see the available subcommands for the currently entered command level. For example, when the cursor is positioned at the beginning of the command line and the Tab key is pressed, the user will see all root (level 0) commands:

```
clear demo shell history log resize version
```

---

**Note:** To view the subcommands that are available for a specific command, you must first type a space after this command and then hit Tab.

---

These commands are registered by various modules, for example:

- clear, shell, history, and resize are built-in commands which have been registered by `subsys/shell/shell.c`
- demo and version have been registered in example code above by `main.c`
- log has been registered by `subsys/logging/log_cmds.c`

Then, if a user types a demo command and presses the Tab key, the shell will only print the subcommands registered for this command:

```
params ping
```

## 7.25.11 API Reference

group shell\_api  
Shell API.

### Defines

SHELL\_CMD\_ARG\_REGISTER(syntax, subcmd, help, handler, mandatory, optional)

Macro for defining and adding a root command (level 0) with required number of arguments.

---

**Note:** Each root command shall have unique syntax. If a command will be called with wrong number of arguments shell will print an error message and command handler will not be called.

---

#### Parameters

- `syntax` – **[in]** Command syntax (for example: history).
- `subcmd` – **[in]** Pointer to a subcommands array.
- `help` – **[in]** Pointer to a command help string.
- `handler` – **[in]** Pointer to a function handler.
- `mandatory` – **[in]** Number of mandatory arguments including command name.
- `optional` – **[in]** Number of optional arguments.

`SHELL_COND_CMD_ARG_REGISTER(flag, syntax, subcmd, help, handler, mandatory, optional)`

Macro for defining and adding a conditional root command (level 0) with required number of arguments.

Macro can be used to create a command which can be conditionally present. It is an alternative to `#ifdefs` around command registration and command handler. If command is disabled handler and subcommands are removed from the application.

**See also:**

[\*SHELL\\_CMD\\_ARG\\_REGISTER\*](#) for details.

#### Parameters

- `flag` – **[in]** Compile time flag. Command is present only if flag exists and equals 1.
- `syntax` – **[in]** Command syntax (for example: history).
- `subcmd` – **[in]** Pointer to a subcommands array.
- `help` – **[in]** Pointer to a command help string.
- `handler` – **[in]** Pointer to a function handler.
- `mandatory` – **[in]** Number of mandatory arguments including command name.
- `optional` – **[in]** Number of optional arguments.

`SHELL_CMD_REGISTER(syntax, subcmd, help, handler)`

Macro for defining and adding a root command (level 0) with arguments.

---

**Note:** All root commands must have different name.

---

#### Parameters

- `syntax` – **[in]** Command syntax (for example: history).
- `subcmd` – **[in]** Pointer to a subcommands array.
- `help` – **[in]** Pointer to a command help string.
- `handler` – **[in]** Pointer to a function handler.

SHELL\_COND\_CMD\_REGISTER(flag, syntax, subcmd, help, handler)

Macro for defining and adding a conditional root command (level 0) with arguments.

**See also:**

[\*SHELL\\_COND\\_CMD\\_ARG\\_REGISTER.\*](#)

#### Parameters

- flag – **[in]** Compile time flag. Command is present only if flag exists and equals 1.
- syntax – **[in]** Command syntax (for example: history).
- subcmd – **[in]** Pointer to a subcommands array.
- help – **[in]** Pointer to a command help string.
- handler – **[in]** Pointer to a function handler.

SHELL\_STATIC\_SUBCMD\_SET\_CREATE(name, ...)

Macro for creating a subcommand set. It must be used outside of any function body.

Example usage: SHELL\_STATIC\_SUBCMD\_SET\_CREATE( foo, [\*SHELL\\_CMD\(abc, ...\)\*](#), [\*SHELL\\_CMD\(def, ...\)\*](#), SHELL\_SUBCMD\_SET\_END )

#### Parameters

- name – **[in]** Name of the subcommand set.
- ... – **[in]** List of commands created with [\*SHELL\\_CMD\\_ARG\*](#) or or [\*SHELL\\_CMD\*](#)

SHELL\_SUBCMD\_SET\_END

Define ending subcommands set.

SHELL\_DYNAMIC\_CMD\_CREATE(name, get)

Macro for creating a dynamic entry.

#### Parameters

- name – **[in]** Name of the dynamic entry.
- get – **[in]** Pointer to the function returning dynamic commands array

SHELL\_CMD\_ARG(syntax, subcmd, help, handler, mand, opt)

Initializes a shell command with arguments.

---

**Note:** If a command will be called with wrong number of arguments shell will print an error message and command handler will not be called.

---

#### Parameters

- syntax – **[in]** Command syntax (for example: history).
- subcmd – **[in]** Pointer to a subcommands array.
- help – **[in]** Pointer to a command help string.
- handler – **[in]** Pointer to a function handler.
- mand – **[in]** Number of mandatory arguments including command name.
- opt – **[in]** Number of optional arguments.

`SHELL_COND_CMD_ARG(flag, syntax, subcmd, help, handler, mand, opt)`

Initializes a conditional shell command with arguments.

**See also:**

[`SHELL\_CMD\_ARG`](#). Based on the flag, creates a valid entry or an empty command which is ignored by the [`shell`](#). It is an alternative to `#ifdefs` around command registration and command handler. However, empty structure is present in the flash even if command is disabled (subcommands and handler are removed). Macro internally handles case if flag is not defined so flag must be provided without any wrapper, e.g.: [`SHELL\_COND\_CMD\_ARG\(CONFIG\_FOO, ...\)`](#)

**Parameters**

- `flag` – **[in]** Compile time flag. Command is present only if flag exists and equals 1.
- `syntax` – **[in]** Command syntax (for example: history).
- `subcmd` – **[in]** Pointer to a subcommands array.
- `help` – **[in]** Pointer to a command help string.
- `handler` – **[in]** Pointer to a function handler.
- `mand` – **[in]** Number of mandatory arguments including command name.
- `opt` – **[in]** Number of optional arguments.

`SHELL_EXPR_CMD_ARG(_expr, _syntax, _subcmd, _help, _handler, _mand, _opt)`

Initializes a conditional shell command with arguments if expression gives non-zero result at compile time.

**See also:**

[`SHELL\_CMD\_ARG`](#). Based on the expression, creates a valid entry or an empty command which is ignored by the [`shell`](#). It should be used instead of [`SHELL\_COND\_CMD\_ARG`](#) if condition is not a single configuration flag, e.g.: [`SHELL\_EXPR\_CMD\_ARG\(IS\_ENABLED\(CONFIG\_FOO\) && IS\_ENABLED\(CONFIG\_FOO\_SETTING\_1\), ...\)`](#)

**Parameters**

- `_expr` – **[in]** Expression.
- `_syntax` – **[in]** Command syntax (for example: history).
- `_subcmd` – **[in]** Pointer to a subcommands array.
- `_help` – **[in]** Pointer to a command help string.
- `_handler` – **[in]** Pointer to a function handler.
- `_mand` – **[in]** Number of mandatory arguments including command name.
- `_opt` – **[in]** Number of optional arguments.

`SHELL_CMD(_syntax, _subcmd, _help, _handler)`

Initializes a shell command.

**Parameters**

- `_syntax` – **[in]** Command syntax (for example: history).
- `_subcmd` – **[in]** Pointer to a subcommands array.

- `_help` – **[in]** Pointer to a command help string.
- `_handler` – **[in]** Pointer to a function handler.

`SHELL_COND_CMD(_flag, _syntax, _subcmd, _help, _handler)`

Initializes a conditional shell command.

**See also:**

[\*SHELL\\_COND\\_CMD\\_ARG.\*](#)

#### Parameters

- `_flag` – **[in]** Compile time flag. Command is present only if flag exists and equals 1.
- `_syntax` – **[in]** Command syntax (for example: history).
- `_subcmd` – **[in]** Pointer to a subcommands array.
- `_help` – **[in]** Pointer to a command help string.
- `_handler` – **[in]** Pointer to a function handler.

`SHELL_EXPR_CMD(_expr, _syntax, _subcmd, _help, _handler)`

Initializes shell command if expression gives non-zero result at compile time.

**See also:**

[\*SHELL\\_EXPR\\_CMD\\_ARG.\*](#)

#### Parameters

- `_expr` – **[in]** Compile time expression. Command is present only if expression is non-zero.
- `_syntax` – **[in]** Command syntax (for example: history).
- `_subcmd` – **[in]** Pointer to a subcommands array.
- `_help` – **[in]** Pointer to a command help string.
- `_handler` – **[in]** Pointer to a function handler.

`SHELL_CMD_DICT_CREATE(_data)`

`SHELL_SUBCMD_DICT_SET_CREATE(_name, _handler, ...)`

Initializes shell dictionary commands.

This is a special kind of static commands. Dictionary commands can be used every time you want to use a pair: (string <-> corresponding data) in a command handler. The string is usually a verbal description of a given data. The idea is to use the string as a command syntax that can be prompted by the shell and corresponding data can be used to process the command.

Example usage: `static int my_handler(const struct shell *shell, size_t argc, char **argv, void *data) { int val = (int)data;`

**See also:**

[\*shell\\_dict\\_cmd\\_handler\*](#)

`shell_print(shell, "(syntax, value) : (%s, %d)", argv[0], val); return 0; }`

```
SHELL_SUBCMD_DICT_SET_CREATE(sub_dict_cmds, my_handler, (value_0, 0), (value_1, 1), (value_2, 2), (value_3, 3) ); SHELL_CMD_REGISTER(dictionary, &sub_dict_cmds, NULL, NULL);
```

#### Parameters

- `_name` – **[in]** Name of the dictionary subcommand set
- `_handler` – **[in]** Command handler common for all dictionary commands.
- ... – **[in]** Dictionary pairs: (command\_syntax, value). Value will be passed to the `_handler` as user data.

`SHELL_DEFINE(_name, _prompt, _transport_iface, _log_queue_size, _log_timeout, _shell_flag)`  
Macro for defining a shell instance.

#### Parameters

- `_name` – **[in]** Instance name.
- `_prompt` – **[in]** Shell default prompt string.
- `_transport_iface` – **[in]** Pointer to the transport interface.
- `_log_queue_size` – **[in]** Logger processing queue size.
- `_log_timeout` – **[in]** Logger thread timeout in milliseconds on full log queue. If queue is full logger thread is blocked for given amount of time before log message is dropped.
- `_shell_flag` – **[in]** Shell output newline sequence.

`SHELL_NORMAL`

Terminal default text color for `shell_fprintf` function.

`SHELL_INFO`

Green text color for `shell_fprintf` function.

`SHELL_OPTION`

Cyan text color for `shell_fprintf` function.

`SHELL_WARNING`

Yellow text color for `shell_fprintf` function.

`SHELL_ERROR`

Red text color for `shell_fprintf` function.

`shell_info(_sh, _ft, ...)`

Print info message to the shell.

See `shell_fprintf`.

#### Parameters

- `_sh` – **[in]** Pointer to the shell instance.
- `_ft` – **[in]** Format string.
- ... – **[in]** List of parameters to print.

`shell_print(_sh, _ft, ...)`

Print normal message to the shell.

See `shell_fprintf`.

**Parameters**

- `_sh` – **[in]** Pointer to the shell instance.
- `_ft` – **[in]** Format string.
- `...` – **[in]** List of parameters to print.

`shell_warn(_sh, _ft, ...)`

Print warning message to the shell.

See `shell_fprintf`.

**Parameters**

- `_sh` – **[in]** Pointer to the shell instance.
- `_ft` – **[in]** Format string.
- `...` – **[in]** List of parameters to print.

`shell_error(_sh, _ft, ...)`

Print error message to the shell.

See `shell_fprintf`.

**Parameters**

- `_sh` – **[in]** Pointer to the shell instance.
- `_ft` – **[in]** Format string.
- `...` – **[in]** List of parameters to print.

`SHELL_CMD_HELP_PRINTED`

## Typedefs

`typedef void (*shell_dynamic_get)(size_t idx, struct shell\_static\_entry *entry)`

Shell dynamic command descriptor.

Function shall fill the received [shell\\_static\\_entry](#) structure with requested (idx) dynamic subcommand data. If there is more than one dynamic subcommand available, the function shall ensure that the returned commands: `entry->syntax` are sorted in alphabetical order. If idx exceeds the available dynamic subcommands, the function must write to `entry->syntax` NULL value. This will indicate to the shell module that there are no more dynamic commands to read.

`typedef int (*shell_cmd_handler)(const struct shell *shell, size_t argc, char **argv)`

Shell command handler prototype.

**Param shell** Shell instance.

**Param argc** Arguments count.

**Param argv** Arguments.

**Retval 0** Successful command execution.

**Retval 1** Help printed and command not executed.

**Retval -EINVAL** Argument validation failed.

**Retval -ENOEXEC** Command not executed.

```
typedef int (*shell_dict_cmd_handler)(const struct shell *shell, size_t argc, char **argv, void *data)
```

Shell dictionary command handler prototype.

**Param shell** Shell instance.

**Param argc** Arguments count.

**Param argv** Arguments.

**Param data** Pointer to the user data.

**Retval 0** Successful command execution.

**Retval 1** Help printed and command not executed.

**Retval -EINVAL** Argument validation failed.

**Retval -ENOEXEC** Command not executed.

```
typedef void (*shell_transport_handler_t)(enum shell_transport_evt evt, void *context)
```

```
typedef void (*shell_uninit_cb_t)(const struct shell *shell, int res)
```

```
typedef void (*shell_bypass_cb_t)(const struct shell *shell, uint8_t *data, size_t len)
```

Bypass callback.

**Param shell** Shell instance.

**Param data** Raw data from transport.

**Param len** Data length.

## Enums

```
enum shell_receive_state
```

*Values:*

enumerator SHELL\_RECEIVE\_DEFAULT

enumerator SHELL\_RECEIVE\_ESC

enumerator SHELL\_RECEIVE\_ESC\_SEQ

enumerator SHELL\_RECEIVE\_TILDE\_EXP

```
enum shell_state
```

*Values:*

enumerator SHELL\_STATE\_UNINITIALIZED

enumerator SHELL\_STATE\_INITIALIZED

enumerator SHELL\_STATE\_ACTIVE

enumerator SHELL\_STATE\_PANIC\_MODE\_ACTIVE

Panic activated.

enumerator SHELL\_STATE\_PANIC\_MODE\_INACTIVE

Panic requested, not supported.

enum shell\_transport\_evt

Shell transport event.

*Values:*

enumerator SHELL\_TRANSPORT\_EVT\_RX\_RDY

enumerator SHELL\_TRANSPORT\_EVT\_TX\_RDY

enum shell\_signal

*Values:*

enumerator SHELL\_SIGNAL\_RXRDY

enumerator SHELL\_SIGNAL\_LOG\_MSG

enumerator SHELL\_SIGNAL\_KILL

enumerator SHELL\_SIGNAL\_TXDONE

enumerator SHELL\_SIGNALS

enum shell\_flag

Flags for setting shell output newline sequence.

*Values:*

enumerator SHELL\_FLAG\_CRLF\_DEFAULT = (1 << 0)

enumerator SHELL\_FLAG\_OLF\_CRLF = (1 << 1)

## Functions

const struct *device* \*shell\_device\_lookup(size\_t idx, const char \*prefix)

Get by index a device that matches .

This can be used, for example, to identify I2C\_1 as the second I2C device.

Devices that failed to initialize or do not have a non-empty name are excluded from the candidates for a match.

### Parameters

- idx – the device number starting from zero.

- `prefix` – optional name prefix used to restrict candidate devices. Indexing is done relative to devices with names that start with this text. Pass null if no prefix match is required.

```
int shell_init(const struct shell *shell, const void *transport_config, bool use_colors, bool
               log_backend, uint32_t init_log_level)
```

Function for initializing a transport layer and internal shell state.

#### Parameters

- `shell` – **[in]** Pointer to shell instance.
- `transport_config` – **[in]** Transport configuration during initialization.
- `use_colors` – **[in]** Enables colored prints.
- `log_backend` – If true, the console will be used as logger backend.
- `init_log_level` – **[in]** Default severity level for the logger.

**Returns** Standard error code.

```
void shell_uninit(const struct shell *shell, shell_uninit_cb_t cb)
```

Uninitializes the transport layer and the internal shell state.

#### Parameters

- `shell` – Pointer to shell instance.
- `cb` – Callback called when uninitialization is completed.

**Returns** Standard error code.

```
int shell_start(const struct shell *shell)
```

Function for starting shell processing.

#### Parameters

- `shell` – Pointer to the shell instance.

**Returns** Standard error code.

```
int shell_stop(const struct shell *shell)
```

Function for stopping shell processing.

#### Parameters

- `shell` – Pointer to shell instance.

**Returns** Standard error code.

```
void shell_fprintf(const struct shell *shell, enum shell_vt100_color color, const char *fmt, ...)
```

printf-like function which sends formatted data stream to the shell.

This function can be used from the command handler or from threads, but not from an interrupt context.

#### Parameters

- `shell` – **[in]** Pointer to the shell instance.
- `color` – **[in]** Printed text color.
- `fmt` – **[in]** Format string.
- `...` – **[in]** List of parameters to print.

```
void shell_vfprintf(const struct shell *shell, enum shell_vt100_color color, const char *fmt,  
                  va_list args)
```

vprintf-like function which sends formatted data stream to the shell.

This function can be used from the command handler or from threads, but not from an interrupt context. It is similar to *shell\_fprintf()* but takes a *va\_list* instead of variable arguments.

#### Parameters

- *shell* – **[in]** Pointer to the shell instance.
- *color* – **[in]** Printed text color.
- *fmt* – **[in]** Format string.
- *args* – **[in]** List of parameters to print.

```
void shell_hexdump_line(const struct shell *shell, unsigned int offset, const uint8_t *data, size_t  
                      len)
```

Print a line of data in hexadecimal format.

Each line shows the offset, bytes and then ASCII representation.

For example:

```
00008010: 20 25 00 20 2f 48 00 08 80 05 00 20 af 46 00 | %. /H.. ... .F. |
```

#### Parameters

- *shell* – **[in]** Pointer to the shell instance.
- *offset* – **[in]** Offset to show for this line.
- *data* – **[in]** Pointer to data.
- *len* – **[in]** Length of data.

```
void shell_hexdump(const struct shell *shell, const uint8_t *data, size_t len)
```

Print data in hexadecimal format.

#### Parameters

- *shell* – **[in]** Pointer to the shell instance.
- *data* – **[in]** Pointer to data.
- *len* – **[in]** Length of data.

```
void shell_process(const struct shell *shell)
```

Process function, which should be executed when data is ready in the transport interface. To be used if shell thread is disabled.

#### Parameters

- *shell* – **[in]** Pointer to the shell instance.

```
int shell_prompt_change(const struct shell *shell, const char *prompt)
```

Change displayed shell prompt.

#### Parameters

- *shell* – **[in]** Pointer to the shell instance.
- *prompt* – **[in]** New shell prompt.

**Returns** 0 Success.

**Returns** -EINVAL Pointer to new prompt is not correct.

`void shell_help(const struct shell *shell)`

Prints the current command help.

Function will print a help string with: the currently entered command and subcommands (if they exist).

#### Parameters

- `shell` – **[in]** Pointer to the shell instance.

`int shell_execute_cmd(const struct shell *shell, const char *cmd)`

Execute command.

Pass command line to shell to execute.

Note: This by no means makes any of the commands a stable interface, so this function should only be used for debugging/diagnostic.

This function must not be called from shell command context!

#### Parameters

- `shell` – **[in]** Pointer to the shell instance. It can be NULL when the **:kconfig: `CONFIG\_SHELL\_BACKEND\_DUMMY`** option is enabled.
- `cmd` – **[in]** Command to be executed.

**Returns** Result of the execution

`int shell_set_root_cmd(const char *cmd)`

Set root command for all shell instances.

It allows setting from the code the root command. It is an equivalent of calling `select command` with one of the root commands as the argument (e.g “select log”) except it sets command for all shell instances.

#### Parameters

- `cmd` – String with one of the root commands or null pointer to reset.

#### Return values

- 0 – if root command is set.
- -EINVAL – if invalid root command is provided.

`void shell_set_bypass(const struct shell *shell, shell_bypass_cb_t bypass)`

Set bypass callback.

Bypass callback is called whenever data is received. Shell is bypassed and data is passed directly to the callback. Use null to disable bypass functionality.

#### Parameters

- `shell` – **[in]** Pointer to the shell instance.
- `bypass` – **[in]** Bypass callback or null to disable.

`int shell_insert_mode_set(const struct shell *shell, bool val)`

Allow application to control text insert mode. Value is modified atomically and the previous value is returned.

#### Parameters

- `shell` – **[in]** Pointer to the shell instance.
- `val` – **[in]** Insert mode.

#### Return values

- 0 – or 1: previous value

- `-EINVAL` – if shell is `NULL`.

`int shell_use_colors_set(const struct shell *shell, bool val)`

Allow application to control whether terminal output uses colored syntax. Value is modified atomically and the previous value is returned.

#### Parameters

- `shell` – **[in]** Pointer to the shell instance.
- `val` – **[in]** Color mode.

#### Return values

- 0 – or 1: previous value
- `-EINVAL` – if shell is `NULL`.

`int shell_echo_set(const struct shell *shell, bool val)`

Allow application to control whether user input is echoed back. Value is modified atomically and the previous value is returned.

#### Parameters

- `shell` – **[in]** Pointer to the shell instance.
- `val` – **[in]** Echo mode.

#### Return values

- 0 – or 1: previous value
- `-EINVAL` – if shell is `NULL`.

`int shell_obscure_set(const struct shell *shell, bool obscure)`

Allow application to control whether user input is obscured with asterisks `&#8212;`; useful for implementing passwords. Value is modified atomically and the previous value is returned.

#### Parameters

- `shell` – **[in]** Pointer to the shell instance.
- `obscure` – **[in]** Obscure mode.

#### Return values

- 0 – or 1: previous value.
- `-EINVAL` – if shell is `NULL`.

`int shell_mode_delete_set(const struct shell *shell, bool val)`

Allow application to control whether the delete key backspaces or deletes. Value is modified atomically and the previous value is returned.

#### Parameters

- `shell` – **[in]** Pointer to the shell instance.
- `val` – **[in]** Delete mode.

#### Return values

- 0 – or 1: previous value
- `-EINVAL` – if shell is `NULL`.

## Variables

`const struct log\_backend\_api log_backend_shell_api`

```
struct shell_cmd_entry
    #include <shell.h> Shell command descriptor.
```

```
union union_cmd_entry
    #include <shell.h>
```

### Public Members

[\*shell\\_dynamic\\_get\*](#) `dynamic_get`  
< Pointer to function returning dynamic commands. Pointer to array of static commands.

const struct [\*shell\\_static\\_entry\*](#) \*entry

```
struct shell_static_args
    #include <shell.h>
```

### Public Members

uint8\_t mandatory  
Number of mandatory arguments.

uint8\_t optional  
Number of optional arguments.

```
struct shell_static_entry
    #include <shell.h>
```

### Public Members

const char \*syntax  
Command syntax strings.

const char \*help  
Command help string.

const struct [\*shell\\_cmd\\_entry\*](#) \*subcmd  
Pointer to subcommand.

[\*shell\\_cmd\\_handler\*](#) handler  
Command handler.

struct [\*shell\\_static\\_args\*](#) args  
Command arguments.

```
struct shell_transport_api
    #include <shell.h> Unified shell transport interface.
```

## Public Members

int (\*init)(const struct *shell\_transport* \*transport, const void \*config,  
*shell\_transport\_handler\_t* evt\_handler, void \*context)

Function for initializing the shell transport interface.

**Param transport [in]** Pointer to the transfer instance.

**Param config [in]** Pointer to instance configuration.

**Param evt\_handler [in]** Event handler.

**Param context [in]** Pointer to the context passed to event handler.

**Return** Standard error code.

int (\*uninit)(const struct *shell\_transport* \*transport)

Function for uninitializing the shell transport interface.

**Param transport [in]** Pointer to the transfer instance.

**Return** Standard error code.

int (\*enable)(const struct *shell\_transport* \*transport, bool blocking\_tx)

Function for enabling transport in given TX mode.

Function can be used to reconfigure TX to work in blocking mode.

**Param transport** Pointer to the transfer instance.

**Param blocking\_tx** If true, the transport TX is enabled in blocking mode.

**Return** NRF\_SUCCESS on successful enabling, error otherwise (also if not supported).

int (\*write)(const struct *shell\_transport* \*transport, const void \*data, size\_t length, size\_t \*cnt)

Function for writing data to the transport interface.

**Param transport [in]** Pointer to the transfer instance.

**Param data [in]** Pointer to the source buffer.

**Param length [in]** Source buffer length.

**Param cnt [out]** Pointer to the sent bytes counter.

**Return** Standard error code.

int (\*read)(const struct *shell\_transport* \*transport, void \*data, size\_t length, size\_t \*cnt)

Function for reading data from the transport interface.

**Param p\_transport [in]** Pointer to the transfer instance.

**Param p\_data [in]** Pointer to the destination buffer.

**Param length [in]** Destination buffer length.

**Param cnt [out]** Pointer to the received bytes counter.

**Return** Standard error code.

void (\*update)(const struct *shell\_transport* \*transport)

Function called in shell thread loop.

Can be used for backend operations that require longer execution time

**Param transport [in]** Pointer to the transfer instance.

struct shell\_transport

*#include <shell.h>*

struct shell\_stats

*#include <shell.h>* Shell statistics structure.

### Public Members

atomic\_t log\_lost\_cnt

Lost log counter.

struct shell\_flags

*#include <shell.h>*

### Public Members

uint32\_t insert\_mode

Controls insert mode for text introduction.

uint32\_t use\_colors

Controls colored syntax.

uint32\_t echo

Controls shell echo.

uint32\_t obscure

If echo on, print asterisk instead

uint32\_t processing

Shell is executing process function.

uint32\_t mode\_delete

Operation mode of backspace key

uint32\_t history\_exit

Request to exit history mode

uint32\_t last\_nl

Last received new line character

uint32\_t cmd\_ctx

Shell is executing command

uint32\_t print\_noinit

Print request from not initialized shell

union shell\_internal

*#include <shell.h>*

### Public Members

uint32\_t value

struct *shell\_flags* flags

struct shell\_ctx

*#include <shell.h>* Shell instance context.

### Public Members

const char \*prompt  
shell current prompt.

enum *shell\_state* state  
Internal module state.

enum *shell\_receive\_state* receive\_state  
Escape sequence indicator. Currently executed command.

const struct *shell\_static\_entry* \*selected\_cmd  
VT100 color and cursor position, terminal width.

struct shell\_vt100\_ctx vt100\_ctx  
Callback called from shell thread context when unitialization is completed just before aborting shell thread.

*shell\_uninit\_cb\_t* uninit\_cb  
When bypass is set, all incoming data is passed to the callback.

uint16\_t cmd\_buff\_len  
Command length.

uint16\_t cmd\_buff\_pos  
Command buffer cursor position.

uint16\_t cmd\_tmp\_buff\_len  
Command length in tmp buffer. Command input buffer.

char cmd\_buff[0]  
Command temporary buffer.

char temp\_buff[0]  
Printf buffer size.

volatile union *shell\_internal* internal  
Internal shell data.

struct shell  
*#include <shell.h>* Shell instance internals.

## Public Members

`const char *default_prompt`  
 shell default prompt.

`const struct shell_transport *iface`  
 Transport interface.

`struct shell_ctx *ctx`  
 Internal context.

## 7.26 Storage

### 7.26.1 Non-Volatile Storage (NVS)

Elements, represented as id-data pairs, are stored in flash using a FIFO-managed circular buffer. The flash area is divided into sectors. Elements are appended to a sector until storage space in the sector is exhausted. Then a new sector in the flash area is prepared for use (erased). Before erasing the sector it is checked that identifier - data pairs exist in the sectors in use, if not the id-data pair is copied.

The id is a 16-bit unsigned number. NVS ensures that for each used id there is at least one id-data pair stored in flash at all time.

NVS allows storage of binary blobs, strings, integers, longs, and any combination of these.

Each element is stored in flash as metadata (8 byte) and data. The metadata is written in a table starting from the end of a nvs sector, the data is written one after the other from the start of the sector. The metadata consists of: id, data offset in sector, data length, part (unused) and a crc.

A write of data to nvs always starts with writing the data, followed by a write of the metadata. Data that is written in flash without metadata is ignored during initialization.

During initialization NVS will verify the data stored in flash, if it encounters an error it will ignore any data with missing/incorrect metadata.

NVS checks the id-data pair before writing data to flash. If the id-data pair is unchanged no write to flash is performed.

To protect the flash area against frequent erases it is important that there is sufficient free space. NVS has a protection mechanism to avoid getting in a endless loop of flash page erases when there is limited free space. When such a loop is detected NVS returns that there is no more space available.

For NVS the file system is declared as:

```
static struct nvs_fs fs = {
    .sector_size = NVS_SECTOR_SIZE,
    .sector_count = NVS_SECTOR_COUNT,
    .offset = NVS_STORAGE_OFFSET,
};
```

where

- `NVS_SECTOR_SIZE` is the sector size, it has to be a multiple of the flash erase page size and a power of 2.
- `NVS_SECTOR_COUNT` is the number of sectors, it is at least 2, one sector is always kept empty to allow copying of existing data.
- `NVS_STORAGE_OFFSET` is the offset of the storage area in flash.

## Flash wear

When writing data to flash a study of the flash wear is important. Flash has a limited life which is determined by the number of times flash can be erased. Flash is erased one page at a time and the pagesize is determined by the hardware. As an example a nRF51822 device has a pagesize of 1024 bytes and each page can be erased about 20,000 times.

**Calculating expected device lifetime** Suppose we use a 4 bytes state variable that is changed every minute and needs to be restored after reboot. NVS has been defined with a `sector_size` equal to the pagesize (1024 bytes) and 2 sectors have been defined.

Each write of the state variable requires 12 bytes of flash storage: 8 bytes for the metadata and 4 bytes for the data. When storing the data the first sector will be full after  $1024/12 = 85.33$  minutes. After another 85.33 minutes, the second sector is full. When this happens, because we're using only two sectors, the first sector will be used for storage and will be erased after 171 minutes of system time. With the expected device life of 20,000 writes, with two sectors writing every 171 minutes, the device should last about  $171 * 20,000$  minutes, or about 6.5 years.

More generally then, with

- NS as the number of storage requests per minute,
- DS as the data size in bytes,
- SECTOR\_SIZE in bytes, and
- PAGE\_ERASES as the number of times the page can be erased,

the expected device life (in minutes) can be calculated as:

```
SECTOR_COUNT * SECTOR_SIZE * PAGE_ERASES / (NS * (DS+8)) minutes
```

From this formula it is also clear what to do in case the expected life is too short: increase `SECTOR_COUNT` or `SECTOR_SIZE`.

## Flash write block size migration

It is possible that during a DFU process, the flash driver used by the NVS changes the supported minimal write block size. The NVS in-flash image will stay compatible unless the physical ATE size changes. Especially, migration between 1,2,4,8-bytes write block sizes is allowed.

## Sample

A sample of how NVS can be used is supplied in `samples/subsys/nvs`.

## Troubleshooting

**MPU fault while using NVS, or -ETIMEDOUT error returned** NVS can use the internal flash of the SoC.

While the MPU is enabled, the flash driver requires MPU RWX access to flash memory, configured using `:kconfig: `CONFIG_MPU_ALLOW_FLASH_WRITE``. If this option is disabled, the NVS application will get an MPU fault if it references the internal SoC flash and it's the only thread running. In a multi-threaded application, another thread might intercept the fault and the NVS API will return an `-ETIMEDOUT` error.

## API Reference

The NVS subsystem APIs are provided by `nvs.h`:

*group* `nvs_data_structures`

Non-volatile Storage Data Structures.

`struct nvs_fs`

*#include* `<nvs.h>` Non-volatile Storage File system structure.

**Param offset** File system offset in flash

**Param ate\_wra** Allocation table entry write address. Addresses are stored as `uint32_t`: high 2 bytes are sector, low 2 bytes are offset in sector,

**Param data\_wra** Data write address.

**Param sector\_size** File system is divided into sectors each sector should be multiple of `pagesize`

**Param sector\_count** Amount of sectors in the file systems

**Param write\_block\_size** Alignment size

**Param nvs\_lock** Mutex

**Param flash\_device** Flash Device

*group* `nvs_high_level_api`

Non-volatile Storage APIs.

## Functions

`int nvs_init(struct nvs_fs *fs, const char *dev_name)`

`nvs_init`

Initializes a NVS file system in flash.

### Parameters

- `fs` – Pointer to file system
- `dev_name` – Pointer to flash device name

### Return values

- 0 – Success
- `-ERRNO` – `errno` code if error

`int nvs_clear(struct nvs_fs *fs)`

`nvs_clear`

Clears the NVS file system from flash.

### Parameters

- `fs` – Pointer to file system

### Return values

- 0 – Success
- `-ERRNO` – `errno` code if error

```
ssize_t nvs_write(struct nvs_fs *fs, uint16_t id, const void *data, size_t len)
```

```
nvs_write
```

Write an entry to the file system.

**Parameters**

- *fs* – Pointer to file system
- *id* – Id of the entry to be written
- *data* – Pointer to the data to be written
- *len* – Number of bytes to be written

**Returns** Number of bytes written. On success, it will be equal to the number of bytes requested to be written. On error returns -ERRNO code.

```
int nvs_delete(struct nvs_fs *fs, uint16_t id)
```

```
nvs_delete
```

Delete an entry from the file system

**Parameters**

- *fs* – Pointer to file system
- *id* – Id of the entry to be deleted

**Return values**

- 0 – Success
- -ERRNO – errno code if error

```
ssize_t nvs_read(struct nvs_fs *fs, uint16_t id, void *data, size_t len)
```

```
nvs_read
```

Read an entry from the file system.

**Parameters**

- *fs* – Pointer to file system
- *id* – Id of the entry to be read
- *data* – Pointer to data buffer
- *len* – Number of bytes to be read

**Returns** Number of bytes read. On success, it will be equal to the number of bytes requested to be read. When the return value is larger than the number of bytes requested to read this indicates not all bytes were read, and more data is available. On error returns -ERRNO code.

```
ssize_t nvs_read_hist(struct nvs_fs *fs, uint16_t id, void *data, size_t len, uint16_t cnt)
```

```
nvs_read_hist
```

Read a history entry from the file system.

**Parameters**

- *fs* – Pointer to file system
- *id* – Id of the entry to be read
- *data* – Pointer to data buffer
- *len* – Number of bytes to be read
- *cnt* – History counter: 0: latest entry, 1:one before latest ...

**Returns** Number of bytes read. On success, it will be equal to the number of bytes requested to be read. When the return value is larger than the number of bytes requested to read this indicates not all bytes were read, and more data is available. On error returns -ERRNO code.

```
ssize_t nvs_calc_free_space(struct nvs_fs *fs)
    nvs_calc_free_space
```

Calculate the available free space in the file system.

#### Parameters

- *fs* – Pointer to file system

**Returns** Number of bytes free. On success, it will be equal to the number of bytes that can still be written to the file system. Calculating the free space is a time consuming operation, especially on spi flash. On error returns -ERRNO code.

## 7.26.2 Disk Access

### Overview

The disk access API provides access to storage devices.

### SD Card support

Zephyr has support for some SD card controllers and support for interfacing SD cards via SPI. These drivers use disk driver interface and a file system can access the SD cards via disk access API. Both standard and high-capacity SD cards are supported.

---

**Note:** The system does not support inserting or removing cards while the system is running. The cards must be present at boot and must not be removed. This may be fixed in future releases.

FAT filesystems are not power safe so the filesystem may become corrupted if power is lost or if the card is removed.

---

**SD Card support via SPI** Example devicetree fragment below shows how to add SD card node to spi1 interface. Example uses pin PA27 for chip select, and runs the SPI bus at 24 MHz once the SD card has been initialized:

```
&spi1 {
    status = "okay";
    cs-gpios = <&porta 27 GPIO_ACTIVE_LOW>;

    sdhc0: sdhc@0 {
        compatible = "zephyr,mmc-spi-slot";
        reg = <0>;
        status = "okay";
        label = "SDHC0";
        spi-max-frequency = <24000000>;
    };
};
```

The SD card will be automatically detected and initialized by the filesystem driver when the board boots. To read and write files and directories, see the *File Systems* in `include/fs.h` such as `fs_open()`, `fs_read()`, and `fs_write()`.

## Disk Access API Configuration Options

Related configuration options:

- `:kconfig: `CONFIG_DISK_ACCESS``

## API Reference

*group* disk\_access\_interface

Disk Access APIs.

### Functions

`int disk_access_init(const char *pdrv)`

perform any initialization

This call is made by the consumer before doing any IO calls so that the disk or the backing device can do any initialization.

#### Parameters

- `pdrv` – **[in]** Disk name

**Returns** 0 on success, negative errno code on fail

`int disk_access_status(const char *pdrv)`

Get the status of disk.

This call is used to get the status of the disk

#### Parameters

- `pdrv` – **[in]** Disk name

**Returns** DISK\_STATUS\_OK or other DISK\_STATUS\_\*s

`int disk_access_read(const char *pdrv, uint8_t *data_buf, uint32_t start_sector, uint32_t num_sector)`

read data from disk

Function to read data from disk to a memory buffer.

#### Parameters

- `pdrv` – **[in]** Disk name
- `data_buf` – **[in]** Pointer to the memory buffer to put data.
- `start_sector` – **[in]** Start disk sector to read from
- `num_sector` – **[in]** Number of disk sectors to read

**Returns** 0 on success, negative errno code on fail

`int disk_access_write(const char *pdrv, const uint8_t *data_buf, uint32_t start_sector, uint32_t num_sector)`

write data to disk

Function write data from memory buffer to disk.

#### Parameters

- `pdrv` – **[in]** Disk name
- `data_buf` – **[in]** Pointer to the memory buffer

- `start_sector` – **[in]** Start disk sector to write to
- `num_sector` – **[in]** Number of disk sectors to write

**Returns** 0 on success, negative `errno` code on fail

`int disk_access_ioctl(const char *pdrv, uint8_t cmd, void *buff)`

Get/Configure disk parameters.

Function to get disk parameters and make any special device requests.

#### Parameters

- `pdrv` – **[in]** Disk name
- `cmd` – **[in]** `DISK_IOCTL_*` code describing the request
- `buff` – **[in]** Command data buffer

**Returns** 0 on success, negative `errno` code on fail

### Disk Driver Configuration Options

Related driver configuration options:

- **`:kconfig: CONFIG_DISK_DRIVERS`**

### Disk Driver Interface

*group* `disk_driver_interface`

Disk Driver Interface.

#### Defines

`DISK_IOCTL_GET_SECTOR_COUNT`

Possible Cmd Codes for `disk_ioctl()`

Get the number of sectors in the disk

`DISK_IOCTL_GET_SECTOR_SIZE`

Get the size of a disk SECTOR in bytes

`DISK_IOCTL_RESERVED`

reserved. It used to be `DISK_IOCTL_GET_DISK_SIZE`

`DISK_IOCTL_GET_ERASE_BLOCK_SZ`

How many sectors constitute a FLASH Erase block

`DISK_IOCTL_CTRL_SYNC`

Commit any cached read/writes to disk

`DISK_STATUS_OK`

Possible return bitmasks for `disk_status()`

Disk status okay

DISK\_STATUS\_UNINIT

Disk status uninitialized

DISK\_STATUS\_NOMEDIA

Disk status no media

DISK\_STATUS\_WR\_PROTECT

Disk status write protected

## Functions

int disk\_access\_register(struct [disk\\_info](#) \*disk)

Register disk.

### Parameters

- `disk` – **[in]** Pointer to the disk info structure

**Returns** 0 on success, negative errno code on fail

int disk\_access\_unregister(struct [disk\\_info](#) \*disk)

Unregister disk.

### Parameters

- `disk` – **[in]** Pointer to the disk info structure

**Returns** 0 on success, negative errno code on fail

struct disk\_info

*#include <disk.h>* Disk info.

## Public Members

[sys\\_dnode\\_t](#) node

Internally used list node

char \*name

Disk name

const struct [disk\\_operations](#) \*ops

Disk operations

const struct [device](#) \*dev

Device associated to this disk

struct disk\_operations

*#include <disk.h>* Disk operations.

### 7.26.3 Flash map

The `<storage/flash_map.h>` API allows accessing information about device flash partitions via `flash_area` structures.

Each `struct flash_area` describes a flash partition. The API provides access to a “flash map”, which contains predefined flash areas accessible via globally unique ID numbers. You can also create `flash_area` structures at runtime for application-specific purposes.

The `flash_area` structure contains the name of the flash device the partition is part of; this name can be passed to `device_get_binding()` to get the corresponding `device` structure which can be read and written to using the `flash API`. The `flash_area` also contains the start offset and size of the partition within the flash memory the device represents.

The `flash_map.h` API provides functions for operating on a `flash_area`. The main examples are `flash_area_read()` and `flash_area_write()`. These functions are basically wrappers around the `flash API` with input parameter range checks. Not all flash APIs have `flash_map.h` wrappers, but `flash_area_get_device()` allows easily retrieving the `struct device` from a `struct flash_area`.

Use `flash_area_open()` to access a `struct flash_area`. This function takes a flash area ID number and returns a pointer to the flash area structure. The ID number for a flash area can be obtained from a human-readable “label” using `FLASH_AREA_ID`; these labels are obtained from the devicetree as described below.

#### Relationship with Devicetree

The `flash_map.h` API uses data generated from the `Devicetree API`, in particular its `Fixed flash partitions`. Zephyr additionally has some partitioning conventions used for `Device Firmware Upgrade` via the MCUboot bootloader, as well as defining partitions usable by `file systems` or other nonvolatile `storage`.

Here is an example devicetree fragment which uses fixed flash partitions for both MCUboot and a storage partition. Some details were left out for clarity.

```
/ {
    soc {
        flashctrl: flash-controller@deadbeef {
            flash0: flash@0 {
                compatible = "soc-nv-flash";
                reg = <0x0 0x100000>;

                partitions {
                    compatible = "fixed-partitions";
                    #address-cells = <0x1>;
                    #size-cells = <0x1>;

                    boot_partition: partition@0 {
                        label = "mcuboot";
                        reg = <0x0 0x10000>;
                        read-only;
                    };
                    storage_partition: partition@1e000 {
                        label = "storage";
                        reg = <0x1e000 0x2000>;
                    };
                    slot0_partition: partition@20000 {
                        label = "image-0";
                        reg = <0x20000 0x60000>;
                    };
                    slot1_partition: partition@80000 {
```

(continues on next page)

(continued from previous page)

```
        label = "image-1";
        reg = <0x80000 0x60000>;
    };
    scratch_partition: partition@e0000 {
        label = "image-scratch";
        reg = <0xe0000 0x20000>;
    };
};
};
};
};
};
};
};
```

Rule for offsets is that each partition offset shall be expressed in relation to the flash memory beginning address to which the partition belong.

The `boot_partition`, `slot0_partition`, `slot1_partition`, and `scratch_partition` nodes are defined for MCUboot, though not all MCUboot configurations require all of them to be defined. See the [MCUboot documentation](#) for more details.

The `storage_partition` node is defined for use by a file system or other nonvolatile storage API.

To get a numeric flash area ID from one of the child nodes of the `partitions` node:

1. take the node's `label` property value
2. lowercase it
3. convert all special characters to underscores (`_`)
4. pass the result **without quotes** to `FLASH_AREA_ID()`

For example, the `flash_area` ID number for `slot0_partition` is `FLASH_AREA_ID(image_0)`.

The same rules apply for other macros which take a “label”, such as `FLASH_AREA_OFFSET` and `FLASH_AREA_SIZE`. For example, `FLASH_AREA_OFFSET(image_0)` would return the start offset for `slot0_partition` within its flash device. This is determined by the node's *reg property*, and in this case is `0x20000`.

To get a pointer to the flash area structure and do something with it starting with a devicetree label like “image-0”, use something like this:

```
struct flash_area *my_area;
int err = flash_area_open(FLASH_AREA_ID(image_0), &my_area);

if (err != 0) {
    handle_the_error(err);
} else {
    flash_area_read(my_area, ...);
}
```

## API Reference

*group* `flash_area_api`

Abstraction over flash partitions/areas and their drivers.

### Defines

SOC\_FLASH\_0\_ID

Provided for compatibility with MCUboot

SPI\_FLASH\_0\_ID

Provided for compatibility with MCUboot

FLASH\_AREA\_LABEL\_EXISTS(label)

FLASH\_AREA\_LABEL\_STR(lbl)

FLASH\_AREA\_ID(label)

FLASH\_AREA\_OFFSET(label)

FLASH\_AREA\_SIZE(label)

## Typedefs

```
typedef void (*flash_area_cb_t)(const struct flash_area *fa, void *user_data)
```

Flash map iteration callback

**Param fa** flash area

**Param user\_data** User supplied data

## Functions

```
int flash_area_open(uint8_t id, const struct flash_area **fa)
```

Retrieve partitions flash area from the flash\_map.

Function Retrieves *flash\_area* from flash\_map for given partition.

### Parameters

- **id** – **[in]** ID of the flash partition.
- **fa** – **[out]** Pointer which has to reference *flash\_area*. If ID is unknown, it will be NULL on output.

**Returns** 0 on success, -EACCES if the flash\_map is not available , -ENOENT if ID is unknown.

```
void flash_area_close(const struct flash_area *fa)
```

Close *flash\_area*.

Reserved for future usage and external projects compatibility reason. Currently is NOP.

### Parameters

- **fa** – **[in]** Flash area to be closed.

```
int flash_area_read(const struct flash_area *fa, off_t off, void *dst, size_t len)
```

Read flash area data.

Read data from flash area. Area readout boundaries are asserted before read request. API has the same limitation regard read-block alignment and size as wrapped flash driver.

### Parameters

- **fa** – **[in]** Flash area
- **off** – **[in]** Offset relative from beginning of flash area to read

- `dst` – **[out]** Buffer to store read data
- `len` – **[in]** Number of bytes to read

**Returns** 0 on success, negative `errno` code on fail.

```
int flash_area_write(const struct flash_area *fa, off_t off, const void *src, size_t len)
```

Write data to flash area.

Write data to flash area. Area write boundaries are asserted before write request. API has the same limitation regard write-block alignment and size as wrapped flash driver.

#### Parameters

- `fa` – **[in]** Flash area
- `off` – **[in]** Offset relative from beginning of flash area to read
- `src` – **[out]** Buffer with data to be written
- `len` – **[in]** Number of bytes to write

**Returns** 0 on success, negative `errno` code on fail.

```
int flash_area_erase(const struct flash_area *fa, off_t off, size_t len)
```

Erase flash area.

Erase given flash area range. Area boundaries are asserted before erase request. API has the same limitation regard erase-block alignment and size as wrapped flash driver.

#### Parameters

- `fa` – **[in]** Flash area
- `off` – **[in]** Offset relative from beginning of flash area.
- `len` – **[in]** Number of bytes to be erase

**Returns** 0 on success, negative `errno` code on fail.

```
uint8_t flash_area_align(const struct flash_area *fa)
```

Get write block size of the flash area.

Currently write block size might be treated as read block size, although most of drivers supports unaligned readout.

#### Parameters

- `fa` – **[in]** Flash area

**Returns** Alignment restriction for flash writes in [B].

```
int flash_area_get_sectors(int fa_id, uint32_t *count, struct flash_sector *sectors)
```

Retrieve info about sectors within the area.

#### Parameters

- `fa_id` – **[in]** Given flash area ID
- `sectors` – **[out]** buffer for sectors data
- `count` – **[inout]** On input Capacity of sectors, on output number of sectors Retrieved.

**Returns** 0 on success, negative `errno` code on fail. Especially returns `-ENOMEM` if There are too many flash pages on the *flash\_area* to fit in the array.

```
void flash_area_foreach(flash_area_cb_t user_cb, void *user_data)
```

Iterate over flash map

#### Parameters

- `user_cb` – User callback
- `user_data` – User supplied data

`int flash_area_has_driver(const struct flash\_area *fa)`

Check whether given flash area has supporting flash driver in the system.

**Parameters**

- `fa` – [in] Flash area.

**Returns** 1 On success. -ENODEV if no driver match.

`const struct device *flash_area_get_device(const struct flash\_area *fa)`

Get driver for given flash area.

**Parameters**

- `fa` – Flash area.

**Returns** device driver.

`uint8_t flash_area_erased_val(const struct flash\_area *fa)`

Get the value expected to be read when accessing any erased flash byte. This API is compatible with the MCUBoot's porting layer.

**Parameters**

- `fa` – Flash area.

**Returns** Byte value of erase memory.

`struct flash_area`

*#include <flash\_map.h>* Flash partition.

This structure represents a fixed-size partition on a flash device. Each partition contains one or more flash sectors.

**Public Members**

`uint8_t fa_id`

ID number

`uint8_t fa_device_id`

Provided for compatibility with MCUboot

`off_t fa_off`

Start offset from the beginning of the flash device

`size_t fa_size`

Total size

`const char *fa_dev_name`

Name of the flash device, suitable for passing to [device\\_get\\_binding\(\)](#).

`struct flash_sector`

*#include <flash\_map.h>* Structure for transfer flash sector boundaries.

This template is used for presentation of flash memory structure. It consumes much less RAM than [flash\\_area](#)

## Public Members

`off_t fs_off`

Sector offset from the beginning of the flash device

`size_t fs_size`

Sector size in bytes

### 7.26.4 Flash Circular Buffer (FCB)

Flash circular buffer provides an abstraction through which you can treat flash like a FIFO. You append entries to the end, and read data from the beginning.

---

**Note:** As of Zephyr release 2.1 the [NVS](#) storage API is recommended over FCB for use as a back-end for the [settings API](#).

---

#### Description

Entries in the flash contain the length of the entry, the data within the entry, and checksum over the entry contents.

Storage of entries in flash is done in a FIFO fashion. When you request space for the next entry, space is located at the end of the used area. When you start reading, the first entry served is the oldest entry in flash.

Entries can be appended to the end of the area until storage space is exhausted. You have control over what happens next; either erase oldest block of data, thereby freeing up some space, or stop writing new data until existing data has been collected. FCB treats underlying storage as an array of flash sectors; when it erases old data, it does this a sector at a time.

Entries in the flash are checksummed. That is how FCB detects whether writing entry to flash completed ok. It will skip over entries which don't have a valid checksum.

#### Usage

To add an entry to circular buffer:

- Call `fcb_append` to get the location where data can be written. If this fails due to lack of space, you can call `fcb_rotate` to erase the oldest sector which will make the space. And then call `fcb_append` again.
- Use `flash_area_write` to write entry contents.
- Call `fcb_append_finish` when done. This completes the writing of the entry by calculating the checksum.

To read contents of the circular buffer:

- Call `fcb_walk` with a pointer to your callback function.
- Within callback function copy in data from the entry using `flash_area_read`. You can tell when all data from within a sector has been read by monitoring the returned entry's area pointer. Then you can call `fcb_rotate`, if you're done with that data.

Alternatively:

- Call `fcb_getnext` with 0 in entry offset to get the pointer to the oldest entry.

- Use `flash_area_read` to read entry contents.
- Call `fc_b_getnext` with pointer to current entry to get the next one. And so on.

## API Reference

The FCB subsystem APIs are provided by `fc_b.h`:

### Data structures

group `fc_b_data_structures`

#### Defines

`FCB_MAX_LEN`

Max length of element

`FCB_ENTRY_FA_DATA_OFF(entry)`

Helper macro for calculating the data offset related to the `fc_b_flash_area` start offset.

#### Parameters

- `entry` – `fc_b` entry structure

struct `fc_b_entry`

`#include <fc_b.h>` FCB entry info structure. This data structure describes the element location in the flash.

You would use it to figure out what parameters to pass to `flash_area_read()` to read element contents. Or to `flash_area_write()` when adding a new element. Entry location is pointer to area (within `fc_b->f_sectors`), and offset within that area.

#### Public Members

struct `flash_sector` \*`fe_sector`

Pointer to info about sector where data are placed

`uint32_t fe_elem_off`

Offset from the start of the sector to beginning of element.

`uint32_t fe_data_off`

Offset from the start of the sector to the start of element.

`uint16_t fe_data_len`

Size of data area in `fc_b` entry

struct `fc_b_entry_ctx`

`#include <fc_b.h>` Structure for transferring complete information about FCB entry location within flash memory.

## Public Members

struct *fcb\_entry* loc

FCB entry info

const struct *flash\_area* \*fap

Flash area where the entry is placed

struct fcb

*#include <fcb.h>* FCB instance structure.

The following data structure describes the FCB itself. First part should be filled in by the user before calling *fcb\_init*. The second part is used by FCB for its internal bookkeeping.

## Public Members

uint32\_t f\_magic

Magic value, should not be 0xFFFFFFFF. It is xored with inversion of f\_erase\_value and placed in the beginning of FCB flash sector. FCB uses this when determining whether sector contains valid data or not. Giving it value of 0xFFFFFFFF means leaving bytes of the file in “erased” state.

uint8\_t f\_version

Current version number of the data

uint8\_t f\_sector\_cnt

Number of elements in sector array

uint8\_t f\_scratch\_cnt

Number of sectors to keep empty. This can be used if you need to have scratch space for garbage collecting when FCB fills up.

struct *flash\_sector* \*f\_sectors

Array of sectors, must be contiguous

struct *k\_mutex* f\_mtx

Locking for accessing the FCB data, internal state

struct *flash\_sector* \*f\_oldest

Pointer to flash sector containing the oldest data, internal state

struct *fcb\_entry* f\_active

internal state

uint16\_t f\_active\_id

Flash location where the newest data is, internal state

uint8\_t f\_align

writes to flash have to aligned to this, internal state

const struct *flash\_area* \*fap

Flash area used by the fcb instance, , internal state. This can be transfer to FCB user

uint8\_t f\_erase\_value

The value flash takes when it is erased. This is read from flash parameters and initialized upon call to fcb\_init.

## API functions

group fcb\_api

Flash Circular Buffer APIs.

## Typedefs

typedef int (\*fcb\_walk\_cb)(struct *fcb\_entry\_ctx* \*loc\_ctx, void \*arg)

FCB Walk callback function type.

Type of function which is expected to be called while walking over fcb entries thanks to a *fcb\_walk* call.

Entry data can be read using *flash\_area\_read()*, using loc\_ctx fields as arguments. If cb wants to stop the walk, it should return non-zero value.

**Param loc\_ctx [in]** entry location information (full context)

**Param arg [inout]** callback context, transferred from *fcb\_walk*.

**Return** 0 continue walking, non-zero stop walking.

## Functions

int fcb\_init(int f\_area\_id, struct *fcb* \*fcb)

Initialize FCB instance.

### Parameters

- f\_area\_id – **[in]** ID of flash area where fcb storage resides.
- fcb – **[inout]** FCB instance structure.

**Returns** 0 on success, non-zero on failure.

int fcb\_append(struct *fcb* \*fcb, uint16\_t len, struct *fcb\_entry* \*loc)

Appends an entry to circular buffer.

When writing the contents for the entry, use loc->fe\_sector and loc->fe\_data\_off with *flash\_area\_write()* to fcb *flash\_area*. When you're finished, call *fcb\_append\_finish()* with loc as argument.

### Parameters

- fcb – **[in]** FCB instance structure.
- len – **[in]** Length of data which are expected to be written as the entry payload.
- loc – **[out]** entry location information

**Returns** 0 on success, non-zero on failure.

```
int fcb_append_finish(struct fcb *fcb, struct fcb_entry *append_loc)
```

Finishes entry append operation.

**Parameters**

- `fcb` – [in] FCB instance structure.
- `append_loc` – [in] entry location information

**Returns** 0 on success, non-zero on failure.

```
int fcb_walk(struct fcb *fcb, struct flash_sector *sector, fcb_walk_cb cb, void *cb_arg)
```

Walk over all entries in the FCB sector

**Parameters**

- `sector` – [in] fcb sector to be walked. If null, traverse entire storage.
- `fcb` – [in] FCB instance structure.
- `cb` – [in] pointer to the function which gets called for every entry. If `cb` wants to stop the walk, it should return non-zero value.
- `cb_arg` – [inout] callback context, transferred to the callback implementation.

**Returns** 0 on success, negative on failure (or transferred form callback return-value), positive transferred form callback return-value

```
int fcb_getnext(struct fcb *fcb, struct fcb_entry *loc)
```

Get next fcb entry location.

Function to obtain fcb entry location in relation to entry pointed by

`loc`. If `loc->fe_sector` is set and `loc->fe_elem_off` is not 0 function fetches next fcb entry location. If `loc->fe_sector` is NULL function fetches the oldest entry location within FCB storage. `loc->fe_sector` is set and `loc->fe_elem_off` is 0 function fetches the first entry location in the fcb sector.

**Parameters**

- `fcb` – [in] FCB instance structure.
- `loc` – [inout] entry location information

**Returns** 0 on success, non-zero on failure.

```
int fcb_rotate(struct fcb *fcb)
```

```
int fcb_append_to_scratch(struct fcb *fcb)
```

```
int fcb_free_sector_cnt(struct fcb *fcb)
```

Get free sector count.

**Parameters**

- `fcb` – [in] FCB instance structure.

**Returns** Number of free sectors.

```
int fcb_is_empty(struct fcb *fcb)
```

Check whether FCB has any data.

**Parameters**

- `fcb` – [in] FCB instance structure.

**Returns** Positive value if fcb is empty, otherwise 0.

```
int fcb_offset_last_n(struct fcb *fcb, uint8_t entries, struct fcb_entry *last_n_entry)
```

Finds the fcb entry that gives back up to n entries at the end.

#### Parameters

- `fcb` – **[in]** FCB instance structure.
- `entries` – **[in]** number of fcb entries the user wants to get
- `last_n_entry` – **[out]** last\_n\_entry the `fcb_entry` to be returned

**Returns** 0 on there are any fcbs available; -ENOENT otherwise

```
int fcb_clear(struct fcb *fcb)
```

Clear fcb instance storage.

#### Parameters

- `fcb` – **[in]** FCB instance structure.

**Returns** 0 on success; non-zero on failure

## 7.26.5 Stream Flash

The Stream Flash module takes contiguous fragments of a stream of data (e.g. from radio packets), aggregates them into a user-provided buffer, then when the buffer fills (or stream ends) writes it to a raw flash partition. It supports providing the read-back buffer to the client to use in validating the persisted stream content.

One typical use of a stream write operation is when receiving a new firmware image to be used in a DFU operation.

There are several reasons why one might want to use buffered writes instead of writing the data directly as it is made available. Some devices have hardware limitations which does not allow flash writes to be performed in parallel with other operations, such as radio RX and TX. Also, fewer write operations result in faster response times seen from the application.

### Persistent stream write progress

Some stream write operations, such as DFU operations, may run for a long time. When performing such long running operations it can be useful to be able to save the stream write progress to persistent storage so that the operation can resume at the same point after an unexpected interruption.

The Stream Flash module offers an API for loading, saving and clearing stream write progress to persistent storage using the `Settings` module. The API can be enabled using `:kconfig: CONFIG_STREAM_FLASH_PROGRESS``.

### API Reference

`group stream_flash`

Abstraction over stream writes to flash.

#### Typedefs

```
typedef int (*stream_flash_callback_t)(uint8_t *buf, size_t len, size_t offset)
```

Signature for callback invoked after flash write completes.

Functions of this type are invoked with a buffer containing data read back from the flash after a flash write has completed. This enables verifying that the data has been correctly stored (for instance by using a SHA function). The write buffer 'buf' provided in `stream_flash_init` is used as a read buffer for this purpose.

**Param buf** Pointer to the data read.

**Param len** The length of the data read.

**Param offset** The offset the data was read from.

## Functions

```
int stream_flash_init(struct stream_flash_ctx *ctx, const struct device *fdev, uint8_t *buf, size_t
    buf_len, size_t offset, size_t size, stream_flash_callback_t cb)
```

Initialize context needed for stream writes to flash.

### Parameters

- `ctx` – context to be initialized
- `fdev` – Flash device to operate on
- `buf` – Write buffer
- `buf_len` – Length of write buffer. Can not be larger than the page size. Must be multiple of the flash device write-block-size.
- `offset` – Offset within flash device to start writing to
- `size` – Number of bytes available for performing buffered write. If this is '0', the size will be set to the total size of the flash device minus the offset.
- `cb` – Callback to be invoked on completed flash write operations.

**Returns** non-negative on success, negative errno code on fail

```
size_t stream_flash_bytes_written(struct stream_flash_ctx *ctx)
```

Read number of bytes written to the flash.

---

**Note:** api-tags: pre-kernel-ok isr-ok

---

### Parameters

- `ctx` – context

**Returns** Number of payload bytes written to flash.

```
int stream_flash_buffered_write(struct stream_flash_ctx *ctx, const uint8_t *data, size_t len,
    bool flush)
```

Process input buffers to be written to flash device in single blocks. Will store remainder between calls.

A final call to this function with `flush` set to true will write out the remaining block buffer to flash.

### Parameters

- `ctx` – context
- `data` – data to write

- `len` – Number of bytes to write
- `flush` – when true this forces any buffered data to be written to flash A flush write should be the last write operation in a sequence of write operations for given context (although this is not mandatory if the total data size is a multiple of the buffer size).

**Returns** non-negative on success, negative `errno` code on fail

`int stream_flash_erase_page(struct stream\_flash\_ctx *ctx, off_t off)`

Erase the flash page to which a given offset belongs.

This function erases a flash page to which an offset belongs if this page is not the page previously erased by the provided `ctx` (`ctx->last_erased_page_start_offset`).

**Parameters**

- `ctx` – context
- `off` – offset from the base address of the flash device

**Returns** non-negative on success, negative `errno` code on fail

`int stream_flash_progress_load(struct stream\_flash\_ctx *ctx, const char *settings_key)`

Load persistent stream write progress stored with key `settings_key`.

This function should be called directly after [stream\\_flash\\_init](#) to load previous stream write progress before writing any data. If the loaded progress has fewer bytes written than `ctx` then it will be ignored.

**Parameters**

- `ctx` – context
- `settings_key` – key to use with the settings module for loading the stream write progress

**Returns** non-negative on success, negative `errno` code on fail

`int stream_flash_progress_save(struct stream\_flash\_ctx *ctx, const char *settings_key)`

Save persistent stream write progress using key `settings_key`.

**Parameters**

- `ctx` – context
- `settings_key` – key to use with the settings module for storing the stream write progress

**Returns** non-negative on success, negative `errno` code on fail

`int stream_flash_progress_clear(struct stream\_flash\_ctx *ctx, const char *settings_key)`

Clear persistent stream write progress stored with key `settings_key`.

**Parameters**

- `ctx` – context
- `settings_key` – key previously used for storing the stream write progress

**Returns** non-negative on success, negative `errno` code on fail

`struct stream_flash_ctx`

`#include <stream_flash.h>` Structure for stream flash context.

Users should treat these structures as opaque values and only interact with them through the below API.

## 7.27 Task Watchdog

### 7.27.1 Overview

Many microcontrollers feature a hardware watchdog timer peripheral. Its purpose is to trigger an action (usually a system reset) in case of severe software malfunctions. Once initialized, the watchdog timer has to be restarted (“fed”) in regular intervals to prevent it from timing out. If the software got stuck and does not manage to feed the watchdog anymore, the corrective action is triggered to bring the system back to normal operation.

In real-time operating systems with multiple tasks running in parallel, a single watchdog instance may not be sufficient anymore, as it can be used for only one task. This software watchdog based on kernel timers provides a method to supervise multiple threads or tasks (called watchdog channels).

An existing hardware watchdog can be used as an optional fallback if the task watchdog itself or the scheduler has a malfunction.

The task watchdog uses a kernel timer as its backend. If configured properly, the timer ISR is never actually called during normal operation, as the timer is continuously updated in the feed calls.

It’s currently not possible to have multiple instances of task watchdogs. Instead, the task watchdog API can be accessed globally to add or delete new channels without passing around a context or device pointer in the firmware.

The maximum number of channels is predefined via Kconfig and should be adjusted to match exactly the number of channels required by the application.

### 7.27.2 Configuration Options

Related configuration options can be found under `subsys/task_wdt/Kconfig`.

- `:kconfig: `CONFIG_TASK_WDT``
- `:kconfig: `CONFIG_TASK_WDT_CHANNELS``
- `:kconfig: `CONFIG_TASK_WDT_HW_FALLBACK``
- `:kconfig: `CONFIG_TASK_WDT_MIN_TIMEOUT``
- `:kconfig: `CONFIG_TASK_WDT_HW_FALLBACK_DELAY``

### 7.27.3 API Reference

`group task_wdt_api`

Task Watchdog APIs.

#### Typedefs

```
typedef void (*task_wdt_callback_t)(int channel_id, void *user_data)
```

Task watchdog callback.

#### Functions

```
int task_wdt_init(const struct device *hw_wdt)
```

Initialize task watchdog.

This function sets up necessary kernel timers and the hardware watchdog (if desired as fallback). It has to be called before *task\_wdt\_add()* and *task\_wdt\_feed()*.

#### Parameters

- *hw\_wdt* – Pointer to the hardware watchdog device used as fallback. Pass NULL if no hardware watchdog fallback is desired.

#### Return values

- 0 – If successful.
- -ENOTSUP – If assigning a hardware watchdog is not supported.

```
int task_wdt_add(uint32_t reload_period, task_wdt_callback_t callback, void *user_data)
```

Install new timeout.

Adds a new timeout to the list of task watchdog channels.

#### Parameters

- *reload\_period* – Period in milliseconds used to reset the timeout
- *callback* – Function to be called when watchdog timer expired. Pass NULL to use system reset handler.
- *user\_data* – User data to associate with the watchdog channel.

#### Return values

- *channel\_id* – If successful, a non-negative value indicating the index of the channel to which the timeout was assigned. This ID is supposed to be used as the parameter in calls to *task\_wdt\_feed()*.
- -EINVAL – If the *reload\_period* is invalid.
- -ENOMEM – If no more timeouts can be installed.

```
int task_wdt_delete(int channel_id)
```

Delete task watchdog channel.

Deletes the specified channel from the list of task watchdog channels. The channel is now available again for other tasks via *task\_wdt\_add()* function.

#### Parameters

- *channel\_id* – Index of the channel as returned by *task\_wdt\_add()*.

#### Return values

- 0 – If successful.
- -EINVAL – If there is no installed timeout for supplied channel.

```
int task_wdt_feed(int channel_id)
```

Feed specified watchdog channel.

This function loops through all installed task watchdogs and updates the internal kernel timer used as for the software watchdog with the next due timeout.

#### Parameters

- *channel\_id* – Index of the fed channel as returned by *task\_wdt\_add()*.

#### Return values

- 0 – If successful.
- -EINVAL – If there is no installed timeout for supplied channel.

## 7.28 Time Utilities

### 7.28.1 Overview

*Uptime* in Zephyr is based on the a tick counter. With the default **:kconfig: CONFIG\_TICKLESS\_KERNEL** this counter advances at a nominally constant rate from zero at the instant the system started. The POSIX equivalent to this counter is something like `CLOCK_MONOTONIC` or, in Linux, `CLOCK_MONOTONIC_RAW`. `k_uptime_get()` provides a millisecond representation of this time.

Applications often need to correlate the Zephyr internal time with external time scales used in daily life, such as local time or Coordinated Universal Time. These systems interpret time in different ways and may have discontinuities due to *leap seconds* and local time offsets like daylight saving time.

Because of these discontinuities, as well as significant inaccuracies in the clocks underlying the cycle counter, the offset between time estimated from the Zephyr clock and the actual time in a “real” civil time scale is not constant and can vary widely over the runtime of a Zephyr application.

The time utilities API supports:

- *converting between time representations*
- *synchronizing and aligning time scales*

For terminology and concepts that support these functions see *Concepts Underlying Time Support in Zephyr*.

### 7.28.2 Time Utility APIs

#### Representation Transformation

Time scale instants can be represented in multiple ways including:

- Seconds since an epoch. POSIX representations of time in this form include `time_t` and `struct timespec`, which are generally interpreted as a representation of “UNIX Time”.
- Calendar time as a year, month, day, hour, minutes, and seconds relative to an epoch. POSIX representations of time in this form include `struct tm`.

Keep in mind that these are simply time representations that must be interpreted relative to a time scale which may be local time, UTC, or some other continuous or discontinuous scale.

Some necessary transformations are available in standard C library routines. For example, `time_t` measuring seconds since the POSIX EPOCH is converted to `struct tm` representing calendar time with `gmtime()`. Sub-second timestamps like `struct timespec` can also use this to produce the calendar time representation and deal with sub-second offsets separately.

The inverse transformation is not standardized: APIs like `mktime()` expect information about time zones. Zephyr provides this transformation with `timeutil_timegm()` and `timeutil_timegm64()`.

group timeutil\_repr\_apis

#### Functions

`int64_t timeutil_timegm64(const struct tm *tm)`

Convert broken-down time to a POSIX epoch offset in seconds.

**See also:**

<http://man7.org/linux/man-pages/man3/timegm.3.html>

**Parameters**

- `tm` – pointer to broken down time.

**Returns** the corresponding time in the POSIX epoch time scale.

```
time_t timeutil_timegm(const struct tm *tm)
```

Convert broken-down time to a POSIX epoch offset in seconds.

**See also:**

<http://man7.org/linux/man-pages/man3/timegm.3.html>

**Parameters**

- `tm` – pointer to broken down time.

**Returns** the corresponding time in the POSIX epoch time scale. If the time cannot be represented then `(time_t)-1` is returned and `errno` is set to `ERANGE`.

**Time Scale Synchronization**

There are several factors that affect synchronizing time scales:

- The rate of discrete instant representation change. For example Zephyr up-time is tracked in ticks which advance at events that nominally occur at **:kconfig: `CONFIG\_SYS\_CLOCK\_TICKS\_PER\_SEC`** Hertz, while an external time source may provide data in whole or fractional seconds (e.g. microseconds).
- The absolute offset required to align the two scales at a single instant.
- The relative error between observable instants in each scale, required to align multiple instants consistently. For example a reference clock that's conditioned by a 1-pulse-per-second GPS signal will be much more accurate than a Zephyr system clock driven by a RC oscillator with a +/- 250 ppm error.

Synchronization or alignment between time scales is done with a multi-step process:

- An instant in a time scale is represented by an (unsigned) 64-bit integer, assumed to advance at a fixed nominal rate.
- `timeutil_sync_config` records the nominal rates of a reference time scale/source (e.g. TAI) and a local time source (e.g. `k_uptime_ticks()`).
- `timeutil_sync_instant` records the representation of a single instant in both the reference and local time scales.
- `timeutil_sync_state` provides storage for an initial instant, a recently received second observation, and a skew that can adjust for relative errors in the actual rate of each time scale.
- `timeutil_sync_ref_from_local()` and `timeutil_sync_local_from_ref()` convert instants in one time scale to another taking into account skew that can be estimated from the two instances stored in the state structure by `timeutil_sync_estimate_skew()`.

group timeutil\_sync\_apis

**Functions**

```
int timeutil_sync_state_update(struct timeutil\_sync\_state *tsp, const struct  
                             timeutil\_sync\_instant *inst)
```

Record a new instant in the time synchronization state.

Note that this updates only the latest persisted instant. The skew is not adjusted automatically.

#### Parameters

- `tsp` – pointer to a [timeutil\\_sync\\_state](#) object.
- `inst` – the new instant to be recorded. This becomes the base instant if there is no base instant, otherwise the value must be strictly after the base instant in both the reference and local time scales.

#### Return values

- 0 – if installation succeeded in providing a new base
- 1 – if installation provided a new latest instant
- -EINVAL – if the new instant is not compatible with the base instant

```
int timeutil_sync_state_set_skew(struct timeutil\_sync\_state *tsp, float skew, const struct  
                                timeutil\_sync\_instant *base)
```

Update the state with a new skew and possibly base value.

Set the skew from a value retrieved from persistent storage, or calculated based on recent skew estimations including from [timeutil\\_sync\\_estimate\\_skew\(\)](#).

Optionally update the base timestamp. If the base is replaced the latest instant will be cleared until [timeutil\\_sync\\_state\\_update\(\)](#) is invoked.

#### Parameters

- `tsp` – pointer to a time synchronization state.
- `skew` – the skew to be used. The value must be positive and shouldn't be too far away from 1.
- `base` – optional new base to be set. If provided this becomes the base timestamp that will be used along with skew to convert between reference and local timescale instants. Setting the base clears the captured latest value.

**Returns** 0 if skew was updated

**Returns** -EINVAL if skew was not valid

```
float timeutil_sync_estimate_skew(const struct timeutil\_sync\_state *tsp)
```

Estimate the skew based on current state.

Using the base and latest syncpoints from the state determine the skew of the local clock relative to the reference clock. See [timeutil\\_sync\\_state::skew](#).

#### Parameters

- `tsp` – pointer to a time synchronization state. The base and latest syncpoints must be present and the latest syncpoint must be after the base point in the local time scale.

**Returns** the estimated skew, or zero if skew could not be estimated.

```
int timeutil_sync_ref_from_local(const struct timeutil\_sync\_state *tsp, uint64_t local,  
                                uint64_t *refp)
```

Interpolate a reference timescale instant from a local instant.

#### Parameters

- `tsp` – pointer to a time synchronization state. This must have a base and a skew installed.

- `local` – an instant measured in the local timescale. This may be before or after the base instant.
- `refp` – where the corresponding instant in the reference timescale should be stored. A negative interpolated reference time produces an error. If interpolation fails the referenced object is not modified.

#### Return values

- 0 – if interpolated using a skew of 1
- 1 – if interpolated using a skew not equal to 1
- `-EINVAL` –
  - the times synchronization state is not adequately initialized
  - `refp` is null
- `-ERANGE` – the interpolated reference time would be negative

```
int timeutil_sync_local_from_ref(const struct timeutil\_sync\_state *tsp, uint64_t ref, int64_t
                                *localp)
```

Interpolate a local timescale instant from a reference instant.

#### Parameters

- `tsp` – pointer to a time synchronization state. This must have a base and a skew installed.
- `ref` – an instant measured in the reference timescale. This may be before or after the base instant.
- `localp` – where the corresponding instant in the local timescale should be stored. An interpolated value before local time 0 is provided without error. If interpolation fails the referenced object is not modified.

#### Return values

- 0 – if successful with a skew of 1
- 1 – if successful with a skew not equal to 1
- `-EINVAL` –
  - the time synchronization state is not adequately initialized
  - `refp` is null

```
int32_t timeutil_sync_skew_to_ppb(float skew)
```

Convert from a skew to an error in parts-per-billion.

A skew of 1.0 has zero error. A skew less than 1 has a positive error (clock is faster than it should be). A skew greater than one has a negative error (clock is slower than it should be).

Note that due to the limited precision of `float` compared with `double` the smallest error that can be represented is about 120 ppb. A “precise” time source may have error on the order of 2000 ppb.

A skew greater than 3.14748 may underflow the 32-bit representation; this represents a clock running at less than 1/3 its nominal rate.

**Returns** skew error represented as parts-per-billion, or `INT32_MIN` if the skew cannot be represented in the return type.

```
struct timeutil_sync_config
```

*#include <timeutil.h>* Immutable state for synchronizing two clocks.

Values required to convert durations between two time scales.

---

**Note:** The accuracy of the translation and calculated skew between sources depends on the resolution of these frequencies. A reference frequency with microsecond or nanosecond resolution would produce the most accurate tracking when the local reference is the Zephyr tick counter. A reference source like an RTC chip with 1 Hz resolution requires a much larger interval between sampled instants to detect relative clock drift.

---

## Public Members

`uint32_t ref_Hz`

The nominal instance counter rate in Hz.

This value is assumed to be precise, but may drift depending on the reference clock source.

The value must be positive.

`uint32_t local_Hz`

The nominal local counter rate in Hz.

This value is assumed to be inaccurate but reasonably stable. For a local clock driven by a crystal oscillator an error of 25 ppm is common; for an RC oscillator larger errors should be expected. The `timeutil_sync` infrastructure can calculate the skew between the local and reference clocks and apply it when converting between time scales.

The value must be positive.

`struct timeutil_sync_instant`

*#include <timeutil.h>* Representation of an instant in two time scales.

Capturing the same instant in two time scales provides a registration point that can be used to convert between those time scales.

## Public Members

`uint64_t ref`

An instant in the reference time scale.

This must never be zero in an initialized `timeutil_sync_instant` object.

`uint64_t local`

The corresponding instance in the local time scale.

This may be zero in a valid `timeutil_sync_instant` object.

`struct timeutil_sync_state`

*#include <timeutil.h>* State required to convert instants between time scales.

This state in conjunction with functions that manipulate it capture the offset information necessary to convert between two timescales along with information that corrects for skew due to inaccuracies in clock rates.

State objects should be zero-initialized before use.

## Public Members

const struct [timeutil\\_sync\\_config](#) \*cfg

Pointer to reference and local rate information.

struct [timeutil\\_sync\\_instant](#) base

The base instant in both time scales.

struct [timeutil\\_sync\\_instant](#) latest

The most recent instant in both time scales.

This is captured here to provide data for skew calculation.

float skew

The scale factor used to correct for clock skew.

The nominal rate for the local counter is assumed to be inaccurate but stable, i.e. it will generally be some parts-per-million faster or slower than specified.

A duration in observed local clock ticks must be multiplied by this value to produce a duration in ticks of a clock operating at the nominal local rate.

A zero value indicates that the skew has not been initialized. If the value is zero when [base](#) is initialized the skew will be set to 1. Otherwise the skew is assigned through [timeutil\\_sync\\_state\\_set\\_skew\(\)](#).

### 7.28.3 Concepts Underlying Time Support in Zephyr

Terms from [ISO/TC 154/WG 5 N0038](#) (ISO/WD 8601-1) and elsewhere:

- A *time axis* is a representation of time as an ordered sequence of instants.
- A *time scale* is a way of representing an instant relative to an origin that serves as the epoch.
- A time scale is *monotonic* (increasing) if the representation of successive time instants never decreases in value.
- A time scale is *continuous* if the representation has no abrupt changes in value, e.g. jumping forward or back when going between successive instants.
- *Civil time* generally refers to time scales that legally defined by civil authorities, like local governments, often to align local midnight to solar time.

#### Relevant Time Scales

[International Atomic Time](#) (TAI) is a time scale based on averaging clocks that count in SI seconds. TAI is a monotonic and continuous time scale.

[Universal Time](#) (UT) is a time scale based on Earth's rotation. UT is a discontinuous time scale as it requires occasional adjustments ([leap seconds](#)) to maintain alignment to changes in Earth's rotation. Thus the difference between TAI and UT varies over time. There are several variants of UT, with [UTC](#) being the most common.

UT times are independent of location. UT is the basis for Standard Time (or “local time”) which is the time at a particular location. Standard time has a fixed offset from UT at any given instant, primarily influenced by longitude, but the offset may be adjusted (“daylight saving time”) to align standard time to the local solar time. In a sense local time is “more discontinuous” than UT.

**POSIX Time** is a time scale that counts seconds since the “POSIX epoch” at 1970-01-01T00:00:00Z (i.e. the start of 1970 UTC). **UNIX Time** is an extension of POSIX time using negative values to represent times before the POSIX epoch. Both of these scales assume that every day has exactly 86400 seconds. In normal use instants in these scales correspond to times in the UTC scale, so they inherit the discontinuity.

The continuous analogue is **UNIX Leap Time** which is UNIX time plus all leap-second corrections added after the POSIX epoch (when TAI-UTC was 8 s).

**Example of Time Scale Differences** A positive leap second was introduced at the end of 2016, increasing the difference between TAI and UTC from 36 seconds to 37 seconds. There was no leap second introduced at the end of 1999, when the difference between TAI and UTC was only 32 seconds. The following table shows relevant civil and epoch times in several scales:

UTC Date	UNIX time	TAI Date	TAI-UTC	UNIX Leap Time
1970-01-01T00:00:00Z	0	1970-01-01T00:00:08	+8	0
1999-12-31T23:59:28Z	946684768	2000-01-01T00:00:00	+32	946684792
1999-12-31T23:59:59Z	946684799	2000-01-01T00:00:31	+32	946684823
2000-01-01T00:00:00Z	946684800	2000-01-01T00:00:32	+32	946684824
2016-12-31T23:59:59Z	1483228799	2017-01-01T00:00:35	+36	1483228827
2016-12-31T23:59:60Z	undefined	2017-01-01T00:00:36	+36	1483228828
2017-01-01T00:00:00Z	1483228800	2017-01-01T00:00:37	+37	1483228829

**Functional Requirements** The Zephyr tick counter has no concept of leap seconds or standard time offsets and is a continuous time scale. However it can be relatively inaccurate, with drifts as much as three minutes per hour (assuming an RC timer with 5% tolerance).

There are two stages required to support conversion between Zephyr time and common human time scales:

- Translation between the continuous but inaccurate Zephyr time scale and an accurate external stable time scale;
- Translation between the stable time scale and the (possibly discontinuous) civil time scale.

The API around `timeutil_sync_state_update()` supports the first step of converting between continuous time scales.

The second step requires external information including schedules of leap seconds and local time offset changes. This may be best provided by an external library, and is not currently part of the time utility APIs.

**Selecting an External Source and Time Scale** If an application requires civil time accuracy within several seconds then UTC could be used as the stable time source. However, if the external source adjusts to a leap second there will be a discontinuity: the elapsed time between two observations taken at 1 Hz is not equal to the numeric difference between their timestamps.

For precise activities a continuous scale that is independent of local and solar adjustments simplifies things considerably. Suitable continuous scales include:

- GPS time: epoch of 1980-01-06T00:00:00Z, continuous following TAI with an offset of TAI-GPS=19 s.
- Bluetooth mesh time: epoch of 2000-01-01T00:00:00Z, continuous following TAI with an offset of -32.
- UNIX Leap Time: epoch of 1970-01-01T00:00:00Z, continuous following TAI with an offset of -8.

Because C and Zephyr library functions support conversion between integral and calendar time representations using the UNIX epoch, UNIX Leap Time is an ideal choice for the external time scale.

The mechanism used to populate synchronization points is not relevant: it may involve reading from a local high-precision RTC peripheral, exchanging packets over a network using a protocol like NTP or PTP, or processing NMEA messages received a GPS with or without a 1pps signal.

## 7.29 USB device stack

- *USB Vendor and Product identifiers*
- *USB device controller drivers*
  - *USB Device Controller API*
- *USB device core layer*
  - *USB Device Core Layer API*
- *USB device class drivers*
  - *Implementing non standard USB class*
- *Testing USB over USP/IP in native\_posix*
- *USB Human Interface Devices (HID) support*
  - *HID Item helpers*
  - *HID Mouse and Keyboard report descriptors*
- *HID Class Device API*

### 7.29.1 USB Vendor and Product identifiers

The USB Vendor ID for the Zephyr project is 0x2FE3. The default USB Product ID for the Zephyr project is 0x100. The USB bcdDevice Device Release Number represents the Zephyr kernel major and minor versions as a binary coded decimal value. When a vendor integrates the Zephyr USB subsystem into a product, the vendor must use the USB Vendor and Product ID assigned to them. A vendor integrating the Zephyr USB subsystem in a product must not use the Vendor ID of the Zephyr project.

The USB maintainer, if one is assigned, or otherwise the Zephyr Technical Steering Committee, may allocate other USB Product IDs based on well-motivated and documented requests.

Each USB sample has its own unique Product ID. When adding a new sample, add a new entry in `samples/subsys/usb/usb_pid.Kconfig` and a Kconfig file inside your sample subdirectory. The following Product IDs are currently used:

- `:kconfig:`CONFIG_USB_PID_CDC_ACM_SAMPLE``
- `:kconfig:`CONFIG_USB_PID_CDC_ACM_COMPOSITE_SAMPLE``
- `:kconfig:`CONFIG_USB_PID_HID_CDC_SAMPLE``
- `:kconfig:`CONFIG_USB_PID_CONSOLE_SAMPLE``
- `:kconfig:`CONFIG_USB_PID_DFU_SAMPLE``
- `:kconfig:`CONFIG_USB_PID_HID_SAMPLE``
- `:kconfig:`CONFIG_USB_PID_HID_MOUSE_SAMPLE``
- `:kconfig:`CONFIG_USB_PID_MASS_SAMPLE``
- `:kconfig:`CONFIG_USB_PID_TESTUSB_SAMPLE``
- `:kconfig:`CONFIG_USB_PID_WEBUSB_SAMPLE``

- `:kconfig: `CONFIG_USB_PID_BLE_HCI_H4_SAMPLE``

## 7.29.2 USB device controller drivers

The Device Controller Driver Layer implements the low level control routines to deal directly with the hardware. All device controller drivers should implement the APIs described in file `usb_dc.h`. This allows the integration of new USB device controllers to be done without changing the upper layers.

### USB Device Controller API

*group* `_usb_device_controller_api`

USB Device Controller API.

#### Typedefs

`typedef void (*usb_dc_ep_callback)(uint8_t ep, enum usb\_dc\_ep\_cb\_status\_code cb_status)`

Callback function signature for the USB Endpoint status

`typedef void (*usb_dc_status_callback)(enum usb\_dc\_status\_code cb_status, const uint8_t *param)`

Callback function signature for the device

#### Enums

`enum usb_dc_status_code`

USB Driver Status Codes.

Status codes reported by the registered device status callback.

*Values:*

enumerator `USB_DC_ERROR`

USB error reported by the controller

enumerator `USB_DC_RESET`

USB reset

enumerator `USB_DC_CONNECTED`

USB connection established, hardware enumeration is completed

enumerator `USB_DC_CONFIGURED`

USB configuration done

enumerator `USB_DC_DISCONNECTED`

USB connection lost

enumerator `USB_DC_SUSPEND`

USB connection suspended by the HOST

enumerator USB\_DC\_RESUME  
USB connection resumed by the HOST

enumerator USB\_DC\_INTERFACE  
USB interface selected

enumerator USB\_DC\_SET\_HALT  
Set Feature ENDPOINT\_HALT received

enumerator USB\_DC\_CLEAR\_HALT  
Clear Feature ENDPOINT\_HALT received

enumerator USB\_DC\_SOF  
Start of Frame received

enumerator USB\_DC\_UNKNOWN  
Initial USB connection status

enum usb\_dc\_ep\_cb\_status\_code  
USB Endpoint Callback Status Codes.  
Status Codes reported by the registered endpoint callback.  
*Values:*

enumerator USB\_DC\_EP\_SETUP  
SETUP received

enumerator USB\_DC\_EP\_DATA\_OUT  
Out transaction on this EP, data is available for read

enumerator USB\_DC\_EP\_DATA\_IN  
In transaction done on this EP

enum usb\_dc\_ep\_transfer\_type  
USB Endpoint Transfer Type.  
*Values:*

enumerator USB\_DC\_EP\_CONTROL = 0  
Control type endpoint

enumerator USB\_DC\_EP\_ISOCHRONOUS  
Isochronous type endpoint

enumerator USB\_DC\_EP\_BULK  
Bulk type endpoint

enumerator USB\_DC\_EP\_INTERRUPT  
Interrupt type endpoint

enum usb\_dc\_ep\_synchronization\_type  
USB Endpoint Synchronization Type.

---

**Note:** Valid only for Isochronous Endpoints

---

*Values:*

enumerator USB\_DC\_EP\_NO\_SYNCHRONIZATION = (0U << 2U)  
No Synchronization

enumerator USB\_DC\_EP\_ASYNCHRONOUS = (1U << 2U)  
Asynchronous

enumerator USB\_DC\_EP\_ADAPTIVE = (2U << 2U)  
Adaptive

enumerator USB\_DC\_EP\_SYNCHRONOUS = (3U << 2U)  
Synchronous

## Functions

int usb\_dc\_attach(void)

Attach USB for device connection.

Function to attach USB for device connection. Upon success, the USB PLL is enabled, and the USB device is now capable of transmitting and receiving on the USB bus and of generating interrupts.

**Returns** 0 on success, negative errno code on fail.

int usb\_dc\_detach(void)

Detach the USB device.

Function to detach the USB device. Upon success, the USB hardware PLL is powered down and USB communication is disabled.

**Returns** 0 on success, negative errno code on fail.

int usb\_dc\_reset(void)

Reset the USB device.

This function returns the USB device and firmware back to it's initial state. N.B. the USB PLL is handled by the usb\_detach function

**Returns** 0 on success, negative errno code on fail.

int usb\_dc\_set\_address(const uint8\_t addr)

Set USB device address.

### Parameters

- addr – [in] Device address

**Returns** 0 on success, negative errno code on fail.

```
void usb_dc_set_status_callback(const usb\_dc\_status\_callback cb)
```

Set USB device controller status callback.

Function to set USB device controller status callback. The registered callback is used to report changes in the status of the device controller. The status code are described by the `usb_dc_status_code` enumeration.

#### Parameters

- `cb` – **[in]** Callback function

```
int usb_dc_ep_check_cap(const struct usb\_dc\_ep\_cfg\_data *const cfg)
```

check endpoint capabilities

Function to check capabilities of an endpoint. [usb\\_dc\\_ep\\_cfg\\_data](#) structure provides the endpoint configuration parameters: endpoint address, endpoint maximum packet size and endpoint type. The driver should check endpoint capabilities and return 0 if the endpoint configuration is possible.

#### Parameters

- `cfg` – **[in]** Endpoint config

**Returns** 0 on success, negative errno code on fail.

```
int usb_dc_ep_configure(const struct usb\_dc\_ep\_cfg\_data *const cfg)
```

Configure endpoint.

Function to configure an endpoint. [usb\\_dc\\_ep\\_cfg\\_data](#) structure provides the endpoint configuration parameters: endpoint address, endpoint maximum packet size and endpoint type.

#### Parameters

- `cfg` – **[in]** Endpoint config

**Returns** 0 on success, negative errno code on fail.

```
int usb_dc_ep_set_stall(const uint8_t ep)
```

Set stall condition for the selected endpoint.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table

**Returns** 0 on success, negative errno code on fail.

```
int usb_dc_ep_clear_stall(const uint8_t ep)
```

Clear stall condition for the selected endpoint.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table

**Returns** 0 on success, negative errno code on fail.

```
int usb_dc_ep_is_stalled(const uint8_t ep, uint8_t *const stalled)
```

Check if the selected endpoint is stalled.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table
- `stalled` – **[out]** Endpoint stall status

**Returns** 0 on success, negative errno code on fail.

```
int usb_dc_ep_halt(const uint8_t ep)
```

Halt the selected endpoint.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table

**Returns** 0 on success, negative `errno` code on fail.

```
int usb_dc_ep_enable(const uint8_t ep)
```

Enable the selected endpoint.

Function to enable the selected endpoint. Upon success interrupts are enabled for the corresponding endpoint and the endpoint is ready for transmitting/receiving data.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table

**Returns** 0 on success, negative `errno` code on fail.

```
int usb_dc_ep_disable(const uint8_t ep)
```

Disable the selected endpoint.

Function to disable the selected endpoint. Upon success interrupts are disabled for the corresponding endpoint and the endpoint is no longer able for transmitting/receiving data.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table

**Returns** 0 on success, negative `errno` code on fail.

```
int usb_dc_ep_flush(const uint8_t ep)
```

Flush the selected endpoint.

This function flushes the FIFOs for the selected endpoint.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table

**Returns** 0 on success, negative `errno` code on fail.

```
int usb_dc_ep_write(const uint8_t ep, const uint8_t *const data, const uint32_t data_len,  
                   uint32_t *const ret_bytes)
```

Write data to the specified endpoint.

This function is called to write data to the specified endpoint. The supplied `usb_ep_callback` function will be called when data is transmitted out.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table
- `data` – **[in]** Pointer to data to write
- `data_len` – **[in]** Length of the data requested to write. This may be zero for a zero length status packet.
- `ret_bytes` – **[out]** Bytes scheduled for transmission. This value may be NULL if the application expects all bytes to be written

**Returns** 0 on success, negative `errno` code on fail.

```
int usb_dc_ep_read(const uint8_t ep, uint8_t *const data, const uint32_t max_data_len, uint32_t
                  *const read_bytes)
```

Read data from the specified endpoint.

This function is called by the endpoint handler function, after an OUT interrupt has been received for that EP. The application must only call this function through the supplied `usb_ep_callback` function. This function clears the ENDPOINT NAK, if all data in the endpoint FIFO has been read, so as to accept more data from host.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table
- `data` – **[in]** Pointer to data buffer to write to
- `max_data_len` – **[in]** Max length of data to read
- `read_bytes` – **[out]** Number of bytes read. If data is NULL and `max_data_len` is 0 the number of bytes available for read should be returned.

**Returns** 0 on success, negative `errno` code on fail.

```
int usb_dc_ep_set_callback(const uint8_t ep, const usb\_dc\_ep\_callback cb)
```

Set callback function for the specified endpoint.

Function to set callback function for notification of data received and available to application or transmit done on the selected endpoint, NULL if callback not required by application code. The callback status code is described by `usb_dc_ep_cb_status_code`.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table
- `cb` – **[in]** Callback function

**Returns** 0 on success, negative `errno` code on fail.

```
int usb_dc_ep_read_wait(uint8_t ep, uint8_t *data, uint32_t max_data_len, uint32_t
                       *read_bytes)
```

Read data from the specified endpoint.

This is similar to `usb_dc_ep_read`, the difference being that, it doesn't clear the endpoint NAKs so that the consumer is not bogged down by further upcalls till he is done with the processing of the data. The caller should reactivate `ep` by invoking [usb\\_dc\\_ep\\_read\\_continue\(\)](#) do so.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table
- `data` – **[in]** Pointer to data buffer to write to
- `max_data_len` – **[in]** Max length of data to read
- `read_bytes` – **[out]** Number of bytes read. If data is NULL and `max_data_len` is 0 the number of bytes available for read should be returned.

**Returns** 0 on success, negative `errno` code on fail.

```
int usb_dc_ep_read_continue(uint8_t ep)
```

Continue reading data from the endpoint.

Clear the endpoint NAK and enable the endpoint to accept more data from the host. Usually called after [usb\\_dc\\_ep\\_read\\_wait\(\)](#) when the consumer is fine to accept more data. Thus these calls together act as a flow control mechanism.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table

**Returns** 0 on success, negative `errno` code on fail.

`int usb_dc_ep_mps(uint8_t ep)`

Get endpoint max packet size.

**Parameters**

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table

**Returns** Endpoint max packet size (mps)

`int usb_dc_wakeup_request(void)`

Start the host wake up procedure.

Function to wake up the host if it's currently in sleep mode.

**Returns** 0 on success, negative `errno` code on fail.

`struct usb_dc_ep_cfg_data`

`#include <usb_dc.h>` USB Endpoint Configuration.

Structure containing the USB endpoint configuration.

**Public Members**

`uint8_t ep_addr`

The number associated with the EP in the device configuration structure IN EP = 0x80 | <endpoint number> OUT EP = 0x00 | <endpoint number>

`uint16_t ep_mps`

Endpoint max packet size

`enum usb\_dc\_ep\_transfer\_type ep_type`

Endpoint Transfer Type. May be Bulk, Interrupt, Control or Isochronous

### 7.29.3 USB device core layer

The USB Device core layer is a hardware independent interface between USB device controller driver and USB device class drivers or customer applications. It's a port of the LPCUSB device stack. It provides the following functionalities:

- Responds to standard device requests and returns standard descriptors, essentially handling 'Chapter 9' processing, specifically the standard device requests in table 9-3 from the universal serial bus specification revision 2.0.
- Provides a programming interface to be used by USB device classes or customer applications. The APIs are described in the `usb_device.h` file.
- Uses the APIs provided by the device controller drivers to interact with the USB device controller.

## USB Device Core Layer API

There are two ways to transmit data, using the ‘low’ level read/write API or the ‘high’ level transfer API.

**Low level API** To transmit data to the host, the class driver should call `usb_write()`. Upon completion the registered endpoint callback will be called. Before sending another packet the class driver should wait for the completion of the previous write. When data is received, the registered endpoint callback is called. `usb_read()` should be used for retrieving the received data. For CDC ACM sample driver this happens via the OUT bulk endpoint handler (`cdc_acm_bulk_out`) mentioned in the endpoint array (`cdc_acm_ep_data`).

**High level API** The `usb_transfer` method can be used to transfer data to/from the host. The transfer API will automatically split the data transmission into one or more USB transaction(s), depending endpoint max packet size. The class driver does not have to implement endpoint callback and should set this callback to the generic `usb_transfer_ep_callback`.

`group _usb_device_core_api`  
USB Device Core Layer API.

### Defines

`USB_TRANS_READ`

`USB_TRANS_WRITE`

`USB_TRANS_NO_ZLP`

### Typedefs

`typedef void (*usb_ep_callback)(uint8_t ep, enum usb\_dc\_ep\_cb\_status\_code cb_status)`

Callback function signature for the USB Endpoint status.

`typedef int (*usb_request_handler)(struct usb_setup_packet *setup, int32_t *transfer_len, uint8_t **payload_data)`

Callback function signature for class specific requests.

Function which handles Class specific requests corresponding to an interface number specified in the device descriptor table. For host to device direction the ‘len’ and ‘payload\_data’ contain the length of the received data and the pointer to the received data respectively. For device to host class requests, ‘len’ and ‘payload\_data’ should be set by the callback function with the length and the address of the data to be transmitted buffer respectively.

`typedef void (*usb_interface_config)(struct usb_desc_header *head, uint8_t bInterfaceNumber)`

Function for interface runtime configuration.

`typedef void (*usb_transfer_callback)(uint8_t ep, int tsize, void *priv)`

Callback function signature for transfer completion.

## Functions

`int usb_set_config(const uint8_t *usb_descriptor)`

Configure USB controller.

Function to configure USB controller. Configuration parameters must be valid or an error is returned

### Parameters

- `usb_descriptor` – **[in]** USB descriptor table

**Returns** 0 on success, negative errno code on fail

`int usb_deconfig(void)`

Deconfigure USB controller.

This function returns the USB device to it's initial state

**Returns** 0 on success, negative errno code on fail

`int usb_enable(usb\_dc\_status\_callback status_cb)`

Enable the USB subsystem and associated hardware.

This function initializes the USB core subsystem and enables the corresponding hardware so that it can begin transmitting and receiving on the USB bus, as well as generating interrupts.

Class-specific initialization and registration must be performed by the user before invoking this, so that any data or events on the bus are processed correctly by the associated class handling code.

### Parameters

- `status_cb` – **[in]** Callback registered by user to notify about USB device controller state.

**Returns** 0 on success, negative errno code on fail.

`int usb_disable(void)`

Disable the USB device.

Function to disable the USB device. Upon success, the specified USB interface is clock gated in hardware, it is no longer capable of generating interrupts.

**Returns** 0 on success, negative errno code on fail

`int usb_write(uint8_t ep, const uint8_t *data, uint32_t data_len, uint32_t *bytes_ret)`

Write data to the specified endpoint.

Function to write data to the specified endpoint. The supplied `usb_ep_callback` will be called when transmission is done.

### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table
- `data` – **[in]** Pointer to data to write
- `data_len` – **[in]** Length of data requested to write. This may be zero for a zero length status packet.
- `bytes_ret` – **[out]** Bytes written to the EP FIFO. This value may be NULL if the application expects all bytes to be written

**Returns** 0 on success, negative errno code on fail

```
int usb_read(uint8_t ep, uint8_t *data, uint32_t max_data_len, uint32_t *ret_bytes)
```

Read data from the specified endpoint.

This function is called by the Endpoint handler function, after an OUT interrupt has been received for that EP. The application must only call this function through the supplied `usb_ep_callback` function.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table
- `data` – **[in]** Pointer to data buffer to write to
- `max_data_len` – **[in]** Max length of data to read
- `ret_bytes` – **[out]** Number of bytes read. If data is NULL and `max_data_len` is 0 the number of bytes available for read is returned.

**Returns** 0 on success, negative errno code on fail

```
int usb_ep_set_stall(uint8_t ep)
```

Set STALL condition on the specified endpoint.

This function is called by USB device class handler code to set stall condition on endpoint.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table

**Returns** 0 on success, negative errno code on fail

```
int usb_ep_clear_stall(uint8_t ep)
```

Clears STALL condition on the specified endpoint.

This function is called by USB device class handler code to clear stall condition on endpoint.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table

**Returns** 0 on success, negative errno code on fail

```
int usb_ep_read_wait(uint8_t ep, uint8_t *data, uint32_t max_data_len, uint32_t *read_bytes)
```

Read data from the specified endpoint.

This is similar to `usb_ep_read`, the difference being that, it doesn't clear the endpoint NAKs so that the consumer is not bogged down by further upcalls till he is done with the processing of the data. The caller should reactivate `ep` by invoking [`usb\_ep\_read\_continue\(\)`](#) do so.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table
- `data` – **[in]** pointer to data buffer to write to
- `max_data_len` – **[in]** max length of data to read
- `read_bytes` – **[out]** Number of bytes read. If data is NULL and `max_data_len` is 0 the number of bytes available for read should be returned.

**Returns** 0 on success, negative errno code on fail.

```
int usb_ep_read_continue(uint8_t ep)
```

Continue reading data from the endpoint.

Clear the endpoint NAK and enable the endpoint to accept more data from the host. Usually called after `usb_ep_read_wait()` when the consumer is fine to accept more data. Thus these calls together acts as flow control mechanism.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table

**Returns** 0 on success, negative errno code on fail.

```
void usb_transfer_ep_callback(uint8_t ep, enum usb_dc_ep_cb_status_code)
```

Transfer management endpoint callback.

If a USB class driver wants to use high-level transfer functions, driver needs to register this callback as usb endpoint callback.

```
int usb_transfer(uint8_t ep, uint8_t *data, size_t dlen, unsigned int flags, usb_transfer_callback cb, void *priv)
```

Start a transfer.

Start a usb transfer to/from the data buffer. This function is asynchronous and can be executed in IRQ context. The provided callback will be called on transfer completion (or error) in thread context.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table
- `data` – **[in]** Pointer to data buffer to write-to/read-from
- `dlen` – **[in]** Size of data buffer
- `flags` – **[in]** Transfer flags (USB\_TRANS\_READ, USB\_TRANS\_WRITE...)
- `cb` – **[in]** Function called on transfer completion/failure
- `priv` – **[in]** Data passed back to the transfer completion callback

**Returns** 0 on success, negative errno code on fail.

```
int usb_transfer_sync(uint8_t ep, uint8_t *data, size_t dlen, unsigned int flags)
```

Start a transfer and block-wait for completion.

Synchronous version of `usb_transfer`, wait for transfer completion before returning.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table
- `data` – **[in]** Pointer to data buffer to write-to/read-from
- `dlen` – **[in]** Size of data buffer
- `flags` – **[in]** Transfer flags

**Returns** number of bytes transferred on success, negative errno code on fail.

```
void usb_cancel_transfer(uint8_t ep)
```

Cancel any ongoing transfer on the specified endpoint.

#### Parameters

- `ep` – **[in]** Endpoint address corresponding to the one listed in the device configuration table

**Returns** 0 on success, negative errno code on fail.

`void usb_cancel_transfers(void)`

Cancel all ongoing transfers.

`bool usb_transfer_is_busy(uint8_t ep)`

Check that transfer is ongoing for the endpoint.

#### Parameters

- `ep` – [**in**] Endpoint address corresponding to the one listed in the device configuration table

**Returns** true if transfer is ongoing, false otherwise.

`int usb_wakeup_request(void)`

Start the USB remote wakeup procedure.

Function to request a remote wakeup. This feature must be enabled in configuration, otherwise it will always return -ENOTSUP error.

**Returns** 0 on success, negative errno code on fail, i.e. when the bus is already active.

`struct usb_ep_cfg_data`

*#include <usb\_device.h>* USB Endpoint Configuration.

This structure contains configuration for the endpoint.

#### Public Members

*usb\_ep\_callback* `ep_cb`

Callback function for notification of data received and available to application or transmit done, NULL if callback not required by application code

`uint8_t ep_addr`

The number associated with the EP in the device configuration structure IN EP = 0x80 | <endpoint number> OUT EP = 0x00 | <endpoint number>

`struct usb_interface_cfg_data`

*#include <usb\_device.h>* USB Interface Configuration.

This structure contains USB interface configuration.

#### Public Members

*usb\_request\_handler* `class_handler`

Handler for USB Class specific Control (EP 0) communications

*usb\_request\_handler* `vendor_handler`

Handler for USB Vendor specific commands

*usb\_request\_handler* `custom_handler`

The custom request handler gets a first chance at handling the request before it is handed over to the 'chapter 9' request handler. return 0 on success, -EINVAL if the request has not been handled by the custom handler and instead needs to be handled by the core USB stack. Any other error code to denote failure within the custom handler.

```
struct usb_cfg_data
```

*#include <usb\_device.h>* USB device configuration.

The Application instantiates this with given parameters added using the “usb\_set\_config” function. Once this function is called changes to this structure will result in undefined behavior. This structure may only be updated after calls to usb\_deconfig

### Public Members

```
const uint8_t *usb_device_description
```

USB device description, see <http://www.beyondlogic.org/usbnutshell/usb5.shtml#DeviceDescriptors>

```
void *interface_descriptor
```

Pointer to interface descriptor

```
usb_interface_config interface_config
```

Function for interface runtime configuration

```
void (*cb_usb_status)(struct usb_cfg_data *cfg, enum usb_dc_status_code cb_status, const uint8_t *param)
```

Callback to be notified on USB connection status change

```
struct usb_interface_cfg_data interface
```

USB interface (Class) handler and storage space

```
uint8_t num_endpoints
```

Number of individual endpoints in the device configuration

```
struct usb_ep_cfg_data *endpoint
```

Pointer to an array of endpoint structs of length equal to the number of EP associated with the device description, not including control endpoints

## 7.29.4 USB device class drivers

Zephyr USB Device Stack supports many standard classes, such as HID, MSC Ethernet over USB, DFU, Bluetooth.

### Implementing non standard USB class

Configuration of USB Device is done in the stack layer.

The following structures and callbacks need to be defined:

- Part of USB Descriptor table
- USB Endpoint configuration table
- USB Device configuration structure
- Endpoint callbacks
- Optionally class, vendor and custom handlers

For example, for USB loopback application:

```

1 struct usb_loopback_config {
2     struct usb_if_descriptor if0;
3     struct usb_ep_descriptor if0_out_ep;
4     struct usb_ep_descriptor if0_in_ep;
5 } __packed;
6
7 USB_DEVICE_DESCRIPTOR_DEFINE(primary, 0) struct usb_loopback_config loopback_cfg = {
8     /* Interface descriptor 0 */
9     .if0 = {
10         .bLength = sizeof(struct usb_if_descriptor),
11         .bDescriptorType = USB_DESC_INTERFACE,
12         .bInterfaceNumber = 0,
13         .bAlternateSetting = 0,
14         .bNumEndpoints = 2,
15         .bInterfaceClass = USB_BCC_VENDOR,
16         .bInterfaceSubClass = 0,
17         .bInterfaceProtocol = 0,
18         .iInterface = 0,
19     },
20
21     /* Data Endpoint OUT */
22     .if0_out_ep = {
23         .bLength = sizeof(struct usb_ep_descriptor),
24         .bDescriptorType = USB_DESC_ENDPOINT,
25         .bEndpointAddress = LOOPBACK_OUT_EP_ADDR,
26         .bmAttributes = USB_DC_EP_BULK,
27         .wMaxPacketSize = sys_cpu_to_le16(CONFIG_LOOPBACK_BULK_EP_MPS),
28         .bInterval = 0x00,
29     },
30
31     /* Data Endpoint IN */
32     .if0_in_ep = {
33         .bLength = sizeof(struct usb_ep_descriptor),
34         .bDescriptorType = USB_DESC_ENDPOINT,
35         .bEndpointAddress = LOOPBACK_IN_EP_ADDR,
36         .bmAttributes = USB_DC_EP_BULK,
37         .wMaxPacketSize = sys_cpu_to_le16(CONFIG_LOOPBACK_BULK_EP_MPS),
38         .bInterval = 0x00,
39     },
40 };

```

Endpoint configuration:

```

1 static struct usb_ep_cfg_data ep_cfg[] = {
2     {
3         .ep_cb = loopback_out_cb,
4         .ep_addr = LOOPBACK_OUT_EP_ADDR,
5     },
6     {
7         .ep_cb = loopback_in_cb,
8         .ep_addr = LOOPBACK_IN_EP_ADDR,
9     },
10 };

```

USB Device configuration structure:

```
1 USBD_CFG_DATA_DEFINE(primary, loopback) struct usb_cfg_data loopback_config = {
2     .usb_device_description = NULL,
3     .interface_config = loopback_interface_config,
4     .interface_descriptor = &loopback_cfg.if0,
5     .cb_usb_status = loopback_status_cb,
6     .interface = {
7         .class_handler = NULL,
8         .custom_handler = NULL,
9         .vendor_handler = loopback_vendor_handler,
10    },
11    .num_endpoints = ARRAY_SIZE(ep_cfg),
12    .endpoint = ep_cfg,
13};
```

The vendor device requests are forwarded by the USB stack core driver to the class driver through the registered vendor handler.

For the loopback class driver, `loopback_vendor_handler()` processes the vendor requests:

```
1 static int loopback_vendor_handler(struct usb_setup_packet *setup,
2                                   int32_t *len, uint8_t **data)
3 {
4     LOG_DBG("Class request: bRequest 0x%x bmRequestType 0x%x len %d",
5            setup->bRequest, setup->bmRequestType, *len);
6
7     if (setup->RequestType.recipient != USB_REQTYPE_RECIPIENT_DEVICE) {
8         return -ENOTSUP;
9     }
10
11     if (usb_reqtype_is_to_device(setup) &&
12         setup->bRequest == 0x5b) {
13         LOG_DBG("Host-to-Device, data %p", *data);
14         /*
15          * Copy request data in loopback_buf buffer and reuse
16          * it later in control device-to-host transfer.
17          */
18         memcpy(loopback_buf, *data,
19                MIN(sizeof(loopback_buf), setup->wLength));
20         return 0;
21     }
22
23     if ((usb_reqtype_is_to_host(setup)) &&
24         (setup->bRequest == 0x5c)) {
25         LOG_DBG("Device-to-Host, wLength %d, data %p",
26                setup->wLength, *data);
27         *data = loopback_buf;
28         *len = MIN(sizeof(loopback_buf), setup->wLength);
29         return 0;
30     }
31
32     return -ENOTSUP;
33 }
```

The class driver waits for the `USB_DC_CONFIGURED` device status code before transmitting any data.

### 7.29.5 Testing USB over USP/IP in native\_posix

Virtual USB controller implemented through USB/IP might be used to test USB Device stack. Follow general build procedure to build USB sample for the native\_posix configuration.

Run built sample with:

```
west build -t run
```

In a terminal window, run the following command to list USB devices:

```
$ usbip list -r localhost
Exportable USB devices
=====
- 127.0.0.1
  1-1: unknown vendor : unknown product (2fe3:0100)
      : /sys/devices/pci0000:00/0000:00:01.2/usb1/1-1
      : (Defined at Interface level) (00/00/00)
      : 0 - Vendor Specific Class / unknown subclass / unknown protocol (ff/00/
↳ 00)
```

In a terminal window, run the following command to attach USB device:

```
$ sudo usbip attach -r localhost -b 1-1
```

The USB device should be connected to your Linux host, and verified with the following commands:

```
$ sudo usbip port
Imported USB devices
=====
Port 00: <Port in Use> at Full Speed(12Mbps)
  unknown vendor : unknown product (2fe3:0100)
  7-1 -> usbip://localhost:3240/1-1
      -> remote bus/dev 001/002
$ lsusb -d 2fe3:0100
Bus 007 Device 004: ID 2fe3:0100
```

### 7.29.6 USB Human Interface Devices (HID) support

#### HID Item helpers

HID item helper macros can be used to compose a HID Report Descriptor. The names correspond to those used in the USB HID Specification.

Example of a HID Report Descriptor:

```
static const uint8_t hid_report_desc[] = {
    HID_USAGE_PAGE(HID_USAGE_GEN_DESKTOP),
    HID_USAGE(HID_USAGE_GEN_DESKTOP_UNDEFINED),
    HID_COLLECTION(HID_COLLECTION_APPLICATION),
    HID_LOGICAL_MIN8(0),
    /* logical maximum 255 */
    HID_LOGICAL_MAX16(0xFF, 0x00),
    HID_REPORT_ID(1),
    HID_REPORT_SIZE(8),
    HID_REPORT_COUNT(1),
    HID_USAGE(HID_USAGE_GEN_DESKTOP_UNDEFINED),
    /* HID_INPUT (Data, Variable, Absolute) */
```

(continues on next page)

(continued from previous page)

```
HID_INPUT(0x02),  
HID_END_COLLECTION,  
};
```

*group* usb\_hid\_items

## Defines

**HID\_ITEM(bTag, bType, bSize)**

Define HID short item.

### Parameters

- **bTag** – Item tag
- **bType** – Item type
- **bSize** – Item data size

**Returns** HID Input item

**HID\_INPUT(a)**

Define HID Input item with the data length of one byte.

For usage examples, see [HID\\_MOUSE\\_REPORT\\_DESC\(\)](#), [HID\\_KEYBOARD\\_REPORT\\_DESC\(\)](#)

### Parameters

- **a** – Input item data

**Returns** HID Input item

**HID\_OUTPUT(a)**

Define HID Output item with the data length of one byte.

For usage examples, see [HID\\_KEYBOARD\\_REPORT\\_DESC\(\)](#)

### Parameters

- **a** – Output item data

**Returns** HID Output item

**HID\_FEATURE(a)**

Define HID Feature item with the data length of one byte.

### Parameters

- **a** – Feature item data

**Returns** HID Feature item

**HID\_COLLECTION(a)**

Define HID Collection item with the data length of one byte.

For usage examples, see [HID\\_MOUSE\\_REPORT\\_DESC\(\)](#), [HID\\_KEYBOARD\\_REPORT\\_DESC\(\)](#)

### Parameters

- **a** – Collection item data

**Returns** HID Collection item

**HID\_END\_COLLECTION**

Define HID End Collection (non-data) item.

For usage examples, see [HID\\_MOUSE\\_REPORT\\_DESC\(\)](#), [HID\\_KEYBOARD\\_REPORT\\_DESC\(\)](#)

**Returns** HID End Collection item

**HID\_USAGE\_PAGE(page)**

Define HID Usage Page item.

For usage examples, see [HID\\_MOUSE\\_REPORT\\_DESC\(\)](#), [HID\\_KEYBOARD\\_REPORT\\_DESC\(\)](#)

**Parameters**

- page – Usage Page

**Returns** HID Usage Page item

**HID\_LOGICAL\_MIN8(a)**

Define HID Logical Minimum item with the data length of one byte.

For usage examples, see [HID\\_MOUSE\\_REPORT\\_DESC\(\)](#), [HID\\_KEYBOARD\\_REPORT\\_DESC\(\)](#)

**Parameters**

- a – Minimum value in logical units

**Returns** HID Logical Minimum item

**HID\_LOGICAL\_MAX8(a)**

Define HID Logical Maximum item with the data length of one byte.

For usage examples, see [HID\\_MOUSE\\_REPORT\\_DESC\(\)](#), [HID\\_KEYBOARD\\_REPORT\\_DESC\(\)](#)

**Parameters**

- a – Maximum value in logical units

**Returns** HID Logical Maximum item

**HID\_LOGICAL\_MIN16(a, b)**

Define HID Logical Minimum item with the data length of two bytes.

**Parameters**

- a – Minimum value lower byte
- b – Minimum value higher byte

**Returns** HID Logical Minimum item

**HID\_LOGICAL\_MAX16(a, b)**

Define HID Logical Maximum item with the data length of two bytes.

**Parameters**

- a – Minimum value lower byte
- b – Minimum value higher byte

**Returns** HID Logical Maximum item

**HID\_LOGICAL\_MIN32(a, b, c, d)**

Define HID Logical Minimum item with the data length of four bytes.

**Parameters**

- a – Minimum value lower byte
- b – Minimum value low middle byte
- c – Minimum value high middle byte

- `d` – Minimum value higher byte

**Returns** HID Logical Minimum item

`HID_LOGICAL_MAX32(a, b, c, d)`

Define HID Logical Maximum item with the data length of four bytes.

**Parameters**

- `a` – Minimum value lower byte
- `b` – Minimum value low middle byte
- `c` – Minimum value high middle byte
- `d` – Minimum value higher byte

**Returns** HID Logical Maximum item

`HID_REPORT_SIZE(size)`

Define HID Report Size item with the data length of one byte.

For usage examples, see [HID\\_MOUSE\\_REPORT\\_DESC\(\)](#), [HID\\_KEYBOARD\\_REPORT\\_DESC\(\)](#)

**Parameters**

- `size` – Report field size in bits

**Returns** HID Report Size item

`HID_REPORT_ID(id)`

Define HID Report ID item with the data length of one byte.

**Parameters**

- `id` – Report ID

**Returns** HID Report ID item

`HID_REPORT_COUNT(count)`

Define HID Report Count item with the data length of one byte.

For usage examples, see [HID\\_MOUSE\\_REPORT\\_DESC\(\)](#), [HID\\_KEYBOARD\\_REPORT\\_DESC\(\)](#)

**Parameters**

- `count` – Number of data fields included in the report

**Returns** HID Report Count item

`HID_USAGE(idx)`

Define HID Usage Index item with the data length of one byte.

For usage examples, see [HID\\_MOUSE\\_REPORT\\_DESC\(\)](#), [HID\\_KEYBOARD\\_REPORT\\_DESC\(\)](#)

**Parameters**

- `idx` – Number of data fields included in the report

**Returns** HID Usage Index item

`HID_USAGE_MIN8(a)`

Define HID Usage Minimum item with the data length of one byte.

For usage examples, see [HID\\_MOUSE\\_REPORT\\_DESC\(\)](#), [HID\\_KEYBOARD\\_REPORT\\_DESC\(\)](#)

**Parameters**

- `a` – Starting Usage

**Returns** HID Usage Minimum item

HID\_USAGE\_MAX8(a)

Define HID Usage Maximum item with the data length of one byte.

For usage examples, see [HID\\_MOUSE\\_REPORT\\_DESC\(\)](#), [HID\\_KEYBOARD\\_REPORT\\_DESC\(\)](#)

**Parameters**

- a – Ending Usage

**Returns** HID Usage Maximum item

HID\_USAGE\_MIN16(a, b)

Define HID Usage Minimum item with the data length of two bytes.

For usage examples, see [HID\\_MOUSE\\_REPORT\\_DESC\(\)](#), [HID\\_KEYBOARD\\_REPORT\\_DESC\(\)](#)

**Parameters**

- a – Starting Usage lower byte
- b – Starting Usage higher byte

**Returns** HID Usage Minimum item

HID\_USAGE\_MAX16(a, b)

Define HID Usage Maximum item with the data length of two bytes.

For usage examples, see [HID\\_MOUSE\\_REPORT\\_DESC\(\)](#), [HID\\_KEYBOARD\\_REPORT\\_DESC\(\)](#)

**Parameters**

- a – Ending Usage lower byte
- b – Ending Usage higher byte

**Returns** HID Usage Maximum item

### **HID Mouse and Keyboard report descriptors**

The pre-defined Mouse and Keyboard report descriptors can be used by a HID device implementation or simply as examples.

*group* `usb_hid_mk_report_desc`

## Defines

`HID_MOUSE_REPORT_DESC(bcmt)`

Simple HID mouse report descriptor for n button mouse.

### Parameters

- `bcmt` – Button count. Allowed values from 1 to 8.

`HID_KEYBOARD_REPORT_DESC()`

Simple HID keyboard report descriptor.

## Enums

`enum hid_kbd_code`

HID keyboard button codes.

*Values:*

enumerator `HID_KEY_A` = 4

enumerator `HID_KEY_B` = 5

enumerator `HID_KEY_C` = 6

enumerator `HID_KEY_D` = 7

enumerator `HID_KEY_E` = 8

enumerator `HID_KEY_F` = 9

enumerator `HID_KEY_G` = 10

enumerator `HID_KEY_H` = 11

enumerator `HID_KEY_I` = 12

enumerator `HID_KEY_J` = 13

enumerator `HID_KEY_K` = 14

enumerator `HID_KEY_L` = 15

enumerator `HID_KEY_M` = 16

enumerator `HID_KEY_N` = 17

enumerator `HID_KEY_O` = 18

enumerator HID\_KEY\_P = 19

enumerator HID\_KEY\_Q = 20

enumerator HID\_KEY\_R = 21

enumerator HID\_KEY\_S = 22

enumerator HID\_KEY\_T = 23

enumerator HID\_KEY\_U = 24

enumerator HID\_KEY\_V = 25

enumerator HID\_KEY\_W = 26

enumerator HID\_KEY\_X = 27

enumerator HID\_KEY\_Y = 28

```

## 7.29.7 HID Class Device API

USB HID devices like mouse, keyboard, or any other specific device use this API.

*group* usb\_hid\_device\_api

### Typedefs

```
typedef int (*hid_cb_t)(const struct device *dev, struct usb_setup_packet *setup, int32_t *len,
uint8_t **data)
```

```
typedef void (*hid_int_ready_callback)(const struct device *dev)
```

```
typedef void (*hid_protocol_cb_t)(const struct device *dev, uint8_t protocol)
```

```
typedef void (*hid_idle_cb_t)(const struct device *dev, uint16_t report_id)
```

### Functions

```
void usb_hid_register_device(const struct device *dev, const uint8_t *desc, size_t size, const
struct hid_ops *op)
```

Register HID device.

#### Parameters

- *dev* – **[in]** Pointer to USB HID device
- *desc* – **[in]** Pointer to HID report descriptor
- *size* – **[in]** Size of HID report descriptor
- *op* – **[in]** Pointer to USB HID device interrupt struct

```
int hid_int_ep_write(const struct device *dev, const uint8_t *data, uint32_t data_len, uint32_t
                    *bytes_ret)
```

Write to USB HID interrupt endpoint buffer.

**Parameters**

- dev – **[in]** Pointer to USB HID device
- data – **[in]** Pointer to data buffer
- data\_len – **[in]** Length of data to copy
- bytes\_ret – **[out]** Bytes written to the EP buffer.

**Returns** 0 on success, negative errno code on fail.

```
int hid_int_ep_read(const struct device *dev, uint8_t *data, uint32_t max_data_len, uint32_t
                   *ret_bytes)
```

Read from USB HID interrupt endpoint buffer.

**Parameters**

- dev – **[in]** Pointer to USB HID device
- data – **[in]** Pointer to data buffer
- max\_data\_len – **[in]** Max length of data to copy
- ret\_bytes – **[out]** Number of bytes to copy. If data is NULL and ret\_bytes is 0 the number of bytes available in the buffer will be returned.

**Returns** 0 on success, negative errno code on fail.

```
int usb_hid_set_proto_code(const struct device *dev, uint8_t proto_code)
```

Set USB HID class Protocol Code.

Should be called before [usb\\_hid\\_init\(\)](#).

**Parameters**

- dev – **[in]** Pointer to USB HID device
- proto\_code – **[in]** Protocol Code to be used for bInterfaceProtocol

**Returns** 0 on success, negative errno code on fail.

```
int usb_hid_init(const struct device *dev)
```

Initialize USB HID class support.

**Parameters**

- dev – **[in]** Pointer to USB HID device

**Returns** 0 on success, negative errno code on fail.

```
struct hid_ops
```

*#include <usb\_hid.h>* USB HID device interface.

## 7.30 User Mode

Zephyr offers the capability to run threads at a reduced privilege level which we call user mode. The current implementation is designed for devices with MPU hardware.

For details on creating threads that run in user mode, please see [Lifecycle](#).

### 7.30.1 Overview

#### Threat Model

User mode threads are considered to be untrusted by Zephyr and are therefore isolated from other user mode threads and from the kernel. A flawed or malicious user mode thread cannot leak or modify the private data/resources of another thread or the kernel, and cannot interfere with or control another user mode thread or the kernel.

Example use-cases of Zephyr's user mode features:

- The kernel can protect against many unintentional programming errors which could otherwise silently or spectacularly corrupt the system.
- The kernel can sandbox complex data parsers such as interpreters, network protocols, and filesystems such that malicious third-party code or data cannot compromise the kernel or other threads.
- The kernel can support the notion of multiple logical “applications”, each with their own group of threads and private data structures, which are isolated from each other if one crashes or is otherwise compromised.

**Design Goals** For threads running in a non-privileged CPU state (hereafter referred to as ‘user mode’) we aim to protect against the following:

- We prevent access to memory not specifically granted, or incorrect access to memory that has an incompatible policy, such as attempting to write to a read-only area.
  - Access to thread stack buffers will be controlled with a policy which partially depends on the underlying memory protection hardware.
    - \* A user thread will by default have read/write access to its own stack buffer.
    - \* A user thread will never by default have access to user thread stacks that are not members of the same memory domain.
    - \* A user thread will never by default have access to thread stacks owned by a supervisor thread, or thread stacks used to handle system call privilege elevations, interrupts, or CPU exceptions.
    - \* A user thread may have read/write access to the stacks of other user threads in the same memory domain, depending on hardware.
      - On MPU systems, threads may only access their own stack buffer.
      - On MMU systems, threads may access any user thread stack in the same memory domain. Portable code should not assume this.
  - By default, program text and read-only data are accessible to all threads on read-only basis, kernel-wide. This policy may be adjusted.
  - User threads by default are not granted default access to any memory except what is noted above.
- We prevent use of device drivers or kernel objects not specifically granted, with the permission granularity on a per object or per driver instance basis.
- We validate kernel or driver API calls with incorrect parameters that would otherwise cause a crash or corruption of data structures private to the kernel. This includes:
  - Using the wrong kernel object type.
  - Using parameters outside of proper bounds or with nonsensical values.
  - Passing memory buffers that the calling thread does not have sufficient access to read or write, depending on the semantics of the API.
  - Use of kernel objects that are not in a proper initialization state.

- We ensure the detection and safe handling of user mode stack overflows.
- We prevent invoking system calls to functions excluded by the kernel configuration.
- We prevent disabling of or tampering with kernel-defined and hardware-enforced memory protections.
- We prevent re-entry from user to supervisor mode except through the kernel-defined system calls and interrupt handlers.
- We prevent the introduction of new executable code by user mode threads, except to the extent to which this is supported by kernel system calls.

We are specifically not protecting against the following attacks:

- The kernel itself, and any threads that are executing in supervisor mode, are assumed to be trusted.
- The toolchain and any supplemental programs used by the build system are assumed to be trusted.
- The kernel build is assumed to be trusted. There is considerable build-time logic for creating the tables of valid kernel objects, defining system calls, and configuring interrupts. The .elf binary files that are worked with during this process are all assumed to be trusted code.
- We can't protect against mistakes made in memory domain configuration done in kernel mode that exposes private kernel data structures to a user thread. RAM for kernel objects should always be configured as supervisor-only.
- It is possible to make top-level declarations of user mode threads and assign them permissions to kernel objects. In general, all C and header files that are part of the kernel build producing zephyr.elf are assumed to be trusted.
- We do not protect against denial of service attacks through thread CPU starvation. Zephyr has no thread priority aging and a user thread of a particular priority can starve all threads of lower priority, and also other threads of the same priority if time-slicing is not enabled.
- There are build-time defined limits on how many threads can be active simultaneously, after which creation of new user threads will fail.
- Stack overflows for threads running in supervisor mode may be caught, but the integrity of the system cannot be guaranteed.

### High-level Policy Details

Broadly speaking, we accomplish these thread-level memory protection goals through the following mechanisms:

- Any user thread will only have access to a subset of memory: typically its stack, program text, read-only data, and any partitions configured in the [Memory Protection Design](#) it belongs to. Access to any other RAM must be done on the thread's behalf through system calls, or specifically granted by a supervisor thread using the memory domain APIs. Newly created threads inherit the memory domain configuration of the parent. Threads may communicate with each other by having shared membership of the same memory domains, or via kernel objects such as semaphores and pipes.
- User threads cannot directly access memory belonging to kernel objects. Although pointers to kernel objects are used to reference them, actual manipulation of kernel objects is done through system call interfaces. Device drivers and threads stacks are also considered kernel objects. This ensures that any data inside a kernel object that is private to the kernel cannot be tampered with.
- User threads by default have no permission to access any kernel object or driver other than their own thread object. Such access must be granted by another thread that is either in supervisor mode or has permission on both the receiving thread object and the kernel object being granted access to. The creation of new threads has an option to automatically inherit permissions of all kernel objects granted to the parent, except the parent thread itself.

- For performance and footprint reasons Zephyr normally does little or no parameter error checking for kernel object or device driver APIs. Access from user mode through system calls involves an extra layer of handler functions, which are expected to rigorously validate access permissions and type of the object, check the validity of other parameters through bounds checking or other means, and verify proper read/write access to any memory buffers involved.
- Thread stacks are defined in such a way that exceeding the specified stack space will generate a hardware fault. The way this is done specifically varies per architecture.

## Constraints

All kernel objects, thread stacks, and device driver instances must be defined at build time if they are to be used from user mode. Dynamic use-cases for kernel objects will need to go through pre-defined pools of available objects.

There are some constraints if additional application binary data is loaded for execution after the kernel starts:

- Loaded object code will not be able to define any kernel objects that will be recognized by the kernel. This code will instead need to use APIs for requesting kernel objects from pools.
- Similarly, since the loaded object code will not be part of the kernel build process, this code will not be able to install interrupt handlers, instantiate device drivers, or define system calls, regardless of what mode it runs in.
- Loaded object code that does not come from a verified source should always be entered with the CPU already in user mode.

## 7.30.2 Memory Protection Design

Zephyr's memory protection design is geared towards microcontrollers with MPU (Memory Protection Unit) hardware. We do support some architectures which have a paged MMU (Memory Management Unit), but in that case the MMU is used like an MPU with an identity page table.

All of the discussion below will be using MPU terminology; systems with MMUs can be considered to have an MPU with an unlimited number of programmable regions.

There are a few different levels on how memory access is configured when Zephyr memory protection features are enabled, which we will describe here:

### Boot Time Memory Configuration

This is the configuration of the MPU after the kernel has started up. It should contain the following:

- Any configuration of memory regions which need to have special caching or write-back policies for basic hardware and driver function. Note that most MPUs have the concept of a default memory access policy map, which can be enabled as a “background” mapping for any area of memory that doesn't have an MPU region configuring it. It is strongly recommended to use this to maximize the number of available MPU regions for the end user. On ARMv7-M/ARMv8-M this is called the System Address Map, other CPUs may have similar capabilities.
- A read-only, executable region or regions for program text and ro-data, that is accessible to user mode. This could be further sub-divided into a read-only region for ro-data, and a read-only, executable region for text, but this will require an additional MPU region. This is required so that threads running in user mode can read ro-data and fetch instructions.
- Depending on configuration, user-accessible read-write regions to support extra features like GCOV, HEP, etc.

Assuming there is a background map which allows supervisor mode to access any memory it needs, and regions are defined which grant user mode access to text/ro-data, this is sufficient for the boot time configuration.

## Hardware Stack Overflow

CONFIG\_HW\_STACK\_PROTECTION is an optional feature which detects stack buffer overflows when the system is running in supervisor mode. This catches issues when the entire stack buffer has overflowed, and not individual stack frames, use compiler-assisted `:kconfig: `CONFIG_STACK_CANARIES`` for that.

Like any crash in supervisor mode, no guarantees can be made about the overall health of the system after a supervisor mode stack overflow, and any instances of this should be treated as a serious error. However it's still very useful to know when these overflows happen, as without robust detection logic the system will either crash in mysterious ways or behave in an undefined manner when the stack buffer overflows.

Some systems implement this feature by creating at runtime a 'guard' MPU region which is set to be read-only and is at either the beginning or immediately preceding the supervisor mode stack buffer. If the stack overflows an exception will be generated.

This feature is optional and is not required to catch stack overflows in user mode; disabling this may free 1-2 MPU regions depending on the MPU design.

Other systems may have dedicated CPU support for catching stack overflows and no extra MPU regions will be required.

## Thread Stack

Any thread running in user mode will need access to its own stack buffer. On context switch into a user mode thread, a dedicated MPU region will be programmed with the bounds of the stack buffer. A thread exceeding its stack buffer will start pushing data onto memory it doesn't have access to and a memory access violation exception will be generated.

## Thread Resource Pools

A small subset of kernel APIs, invoked as system calls, require heap memory allocations. This memory is used only by the kernel and is not accessible directly by user mode. In order to use these system calls, invoking threads must assign themselves to a resource pool, which is a `k_mem_pool` object. Memory is drawn from a thread's resource pool using `z_thread_malloc()` and freed with `k_free()`.

The APIs which use resource pools are as follows, with any alternatives noted for users who do not want heap allocations within their application:

- `k_stack_alloc_init()` sets up a `k_stack` with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare `k_stacks` that are automatically initialized at boot with `K_STACK_DEFINE()`, or to initialize the `k_stack` in supervisor mode with `k_stack_init()`.
- `k_pipe_alloc_init()` sets up a `k_pipe` object with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare `k_pipes` that are automatically initialized at boot with `K_PIPE_DEFINE()`, or to initialize the `k_pipe` in supervisor mode with `k_pipe_init()`.
- `k_msgq_alloc_init()` sets up a `k_msgq` object with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare a `k_msgq` that is automatically initialized at boot with `K_MSGQ_DEFINE()`, or to initialize the `k_msgq` in supervisor mode with `k_msgq_init()`.
- `k_poll()` when invoked from user mode, needs to make a kernel-side copy of the provided events array while waiting for an event. This copy is freed when `k_poll()` returns for any reason.

- `k_queue_alloc_prepend()` and `k_queue_alloc_append()` allocate a container structure to place the data in, since the internal bookkeeping information that defines the queue cannot be placed in the memory provided by the user.
- `k_object_alloc()` allows for entire kernel objects to be dynamically allocated at runtime and a usable pointer to them returned to the caller.

The relevant API is `k_thread_heap_assign()` which assigns a `k_heap` to draw these allocations from for the target thread.

If the system heap is enabled, then the system heap may be used with `k_thread_system_pool_assign()`, but it is preferable for different logical applications running on the system to have their own pools.

## Memory Domains

The kernel ensures that any user thread will have access to its own stack buffer, plus program text and read-only data. The memory domain APIs are the way to grant access to additional blocks of memory to a user thread.

Conceptually, a memory domain is a collection of some number of memory partitions. The maximum number of memory partitions in a domain is limited by the number of available MPU regions. This is why it is important to minimize the number of boot-time MPU regions.

Memory domains are *not* intended to control access to memory from supervisor mode. In some cases this may be unavoidable; for example some architectures do not allow for the definition of regions which are read-only to user mode but read-write to supervisor mode. A great deal of care must be taken when working with such regions to not unintentionally cause the kernel to crash when accessing such a region. Any attempt to use memory domain APIs to control supervisor mode access is at best undefined behavior; supervisor mode access policy is only intended to be controlled by boot-time memory regions.

Memory domain APIs are only available to supervisor mode. The only control user mode has over memory domains is that any user thread's child threads will automatically become members of the parent's domain.

All threads are members of a memory domain, including supervisor threads (even though this has no implications on their memory access). There is a default domain `k_mem_domain_default` which will be assigned to threads if they have not been specifically assigned to a domain, or inherited a memory domain membership from their parent thread. The main thread starts as a member of the default domain.

**Memory Partitions** Each memory partition consists of a memory address, a size, and access attributes. It is intended that memory partitions are used to control access to system memory. Defining memory partitions are subject to the following constraints:

- The partition must represent a memory region that can be programmed by the underlying memory management hardware, and needs to conform to any underlying hardware constraints. For example, many MPU-based systems require that partitions be sized to some power of two, and aligned to their own size. For MMU-based systems, the partition must be aligned to a page and the size some multiple of the page size.
- Partitions within the same memory domain may not overlap each other. There is no notion of precedence among partitions within a memory domain. Partitions within a memory domain are assumed to have a higher precedence than any boot-time memory regions, however whether a memory domain partition can overlap a boot-time memory region is architecture specific.
- The same partition may be specified in multiple memory domains. For example there may be a shared memory area that multiple domains grant access to.
- Care must be taken in determining what memory to expose in a partition. It is not appropriate to provide direct user mode access to any memory containing private kernel data.

- Memory domain partitions are intended to control access to system RAM. Configuration of memory partitions which do not correspond to RAM may not be supported by the architecture; this is true for MMU-based systems.

There are two ways to define memory partitions: either manually or automatically.

**Manual Memory Partitions** The following code declares a global array `buf`, and then declares a read-write partition for it which may be added to a domain:

```
uint8_t __aligned(32) buf[32];

K_MEM_PARTITION_DEFINE(my_partition, buf, sizeof(buf),
    K_MEM_PARTITION_P_RW_U_RW);
```

This does not scale particularly well when we are trying to contain multiple objects spread out across several C files into a single partition.

**Automatic Memory Partitions** Automatic memory partitions are created by the build system. All globals which need to be placed inside a partition are tagged with their destination partition. The build system will then coalesce all of these into a single contiguous block of memory, zero any BSS variables at boot, and define a memory partition of appropriate base address and size which contains all the tagged data.

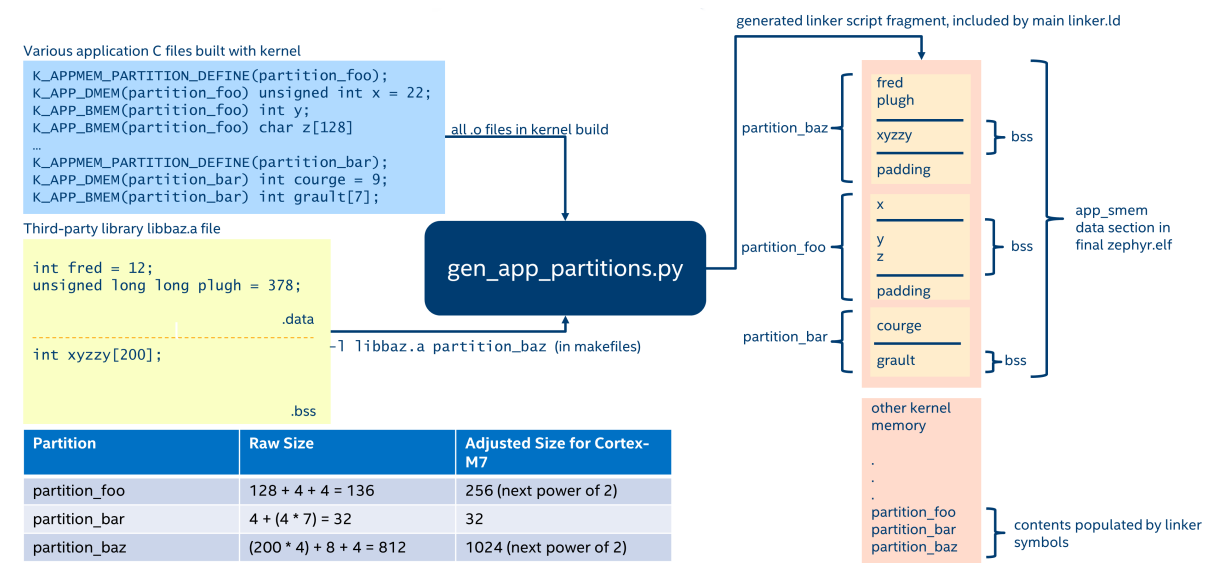

Fig. 9: Automatic Memory Domain build flow

Automatic memory partitions are only configured as read-write regions. They are defined with `K_APPMEM_PARTITION_DEFINE()`. Global variables are then routed to this partition using `K_APP_DMEN()` for initialized data and `K_APP_BMEM()` for BSS.

```
#include <app_memory/app_memdomain.h>

/* Declare a k_mem_partition "my_partition" that is read-write to
 * user mode. Note that we do not specify a base address or size.
 */
K_APPMEM_PARTITION_DEFINE(my_partition);

/* The global variable var1 will be inside the bounds of my_partition
 * and be initialized with 37 at boot.
```

(continues on next page)

(continued from previous page)

```
*/
K_APP_DMEN(my_partition) int var1 = 37;

/* The global variable var2 will be inside the bounds of my_partition
 * and be zeroed at boot size K_APP_BMEM() was used, indicating a BSS
 * variable.
 */
K_APP_BMEM(my_partition) int var2;
```

The build system will ensure that the base address of `my_partition` will be properly aligned, and the total size of the region conforms to the memory management hardware requirements, adding padding if necessary.

If multiple partitions are being created, a variadic preprocessor macro can be used as provided in `app_macro_support.h`:

```
FOR_EACH(K_APPMEM_PARTITION_DEFINE, part0, part1, part2);
```

**Automatic Partitions for Static Library Globals** The build-time logic for setting up automatic memory partitions is in `scripts/gen_app_partitions.py`. If a static library is linked into Zephyr, it is possible to route all the globals in that library to a specific memory partition with the `--library` argument.

For example, if the Newlib C library is enabled, the Newlib globals all need to be placed in `z_libc_partition`. The invocation of the script in the top-level `CMakeLists.txt` adds the following:

```
gen_app_partitions.py ... --library libc.a z_libc_partition ..
```

For pre-compiled libraries there is no support for expressing this in the project-level configuration or build files; the toplevel `CMakeLists.txt` must be edited.

For Zephyr libraries created using `zephyr_library` or `zephyr_library_named` the `zephyr_library_app_memory` function can be used to specify the memory partition where all globals in the library should be placed.

**Pre-defined Memory Partitions** There are a few memory partitions which are pre-defined by the system:

- `z_malloc_partition` - This partition contains the system-wide pool of memory used by `libc malloc()`. Due to possible starvation issues, it is not recommended to draw heap memory from a global pool, instead it is better to define various `sys_heap` objects and assign them to specific memory domains.
- `z_libc_partition` - Contains globals required by the C library and runtime. Required when using either the Minimal C library or the Newlib C Library. Required when option: `CONFIG_STACK_CANARIES` is enabled.

Library-specific partitions are listed in `include/app_memory/partitions.h`. For example, to use the MBEDTLS library from user mode, the `k_mbedtls_partition` must be added to the domain.

## Memory Domain Usage

**Create a Memory Domain** A memory domain is defined using a variable of type `k_mem_domain`. It must then be initialized by calling `k_mem_domain_init()`.

The following code defines and initializes an empty memory domain.

```
struct k_mem_domain app0_domain;

k_mem_domain_init(&app0_domain, 0, NULL);
```

**Add Memory Partitions into a Memory Domain** There are two ways to add memory partitions into a memory domain.

This first code sample shows how to add memory partitions while creating a memory domain.

```
/* the start address of the MPU region needs to align with its size */
uint8_t __aligned(32) app0_buf[32];
uint8_t __aligned(32) app1_buf[32];

K_MEM_PARTITION_DEFINE(app0_part0, app0_buf, sizeof(app0_buf),
                       K_MEM_PARTITION_P_RW_U_RW);

K_MEM_PARTITION_DEFINE(app0_part1, app1_buf, sizeof(app1_buf),
                       K_MEM_PARTITION_P_RW_U_RO);

struct k_mem_partition *app0_parts[] = {
    app0_part0,
    app0_part1
};

k_mem_domain_init(&app0_domain, ARRAY_SIZE(app0_parts), app0_parts);
```

This second code sample shows how to add memory partitions into an initialized memory domain one by one.

```
/* the start address of the MPU region needs to align with its size */
uint8_t __aligned(32) app0_buf[32];
uint8_t __aligned(32) app1_buf[32];

K_MEM_PARTITION_DEFINE(app0_part0, app0_buf, sizeof(app0_buf),
                       K_MEM_PARTITION_P_RW_U_RW);

K_MEM_PARTITION_DEFINE(app0_part1, app1_buf, sizeof(app1_buf),
                       K_MEM_PARTITION_P_RW_U_RO);

k_mem_domain_add_partition(&app0_domain, &app0_part0);
k_mem_domain_add_partition(&app0_domain, &app0_part1);
```

---

**Note:** The maximum number of memory partitions is limited by the maximum number of MPU regions or the maximum number of MMU tables.

---

**Memory Domain Assignment** Any thread may join a memory domain, and any memory domain may have multiple threads assigned to it. Threads are assigned to memory domains with an API call:

```
k_mem_domain_add_thread(&app0_domain, app_thread_id);
```

If the thread was already a member of some other domain (including the default domain), it will be removed from it in favor of the new one.

In addition, if a thread is a member of a memory domain, and it creates a child thread, that thread will belong to the domain as well.

**Remove a Memory Partition from a Memory Domain** The following code shows how to remove a memory partition from a memory domain.

```
k_mem_domain_remove_partition(&app0_domain, &app0_part1);
```

The `k_mem_domain_remove_partition()` API finds the memory partition that matches the given parameter and removes that partition from the memory domain.

**Available Partition Attributes** When defining a partition, we need to set access permission attributes to the partition. Since the access control of memory partitions relies on either an MPU or MMU, the available partition attributes would be architecture dependent.

The complete list of available partition attributes for a specific architecture is found in the architecture-specific include file `include/arch/<arch name>/arch.h`, (for example, `include/arch/arm/aarch32/arch.h`.) Some examples of partition attributes are:

```
/* Denote partition is privileged read/write, unprivileged read/write */
K_MEM_PARTITION_P_RW_U_RW
/* Denote partition is privileged read/write, unprivileged read-only */
K_MEM_PARTITION_P_RW_U_RO
```

In almost all cases `K_MEM_PARTITION_P_RW_U_RW` is the right choice.

## Configuration Options

Related configuration options:

- `:kconfig: `CONFIG_MAX_DOMAIN_PARTITIONS``

## API Reference

The following memory domain APIs are provided by `include/kernel.h`:

`group mem_domain_apis`

### Defines

`K_MEM_PARTITION_DEFINE(name, start, size, attr)`

Statically declare a memory partition.

### Functions

`void k_mem_domain_init(struct k_mem_domain *domain, uint8_t num_parts, struct k_mem_partition *parts[])`

Initialize a memory domain.

Initialize a memory domain with given name and memory partitions.

See documentation for `k_mem_domain_add_partition()` for details about partition constraints.

Do not call `k_mem_domain_init()` on the same memory domain more than once, doing so is undefined behavior.

#### Parameters

- `domain` – The memory domain to be initialized.

- `num_parts` – The number of array items of “parts” parameter.
- `parts` – An array of pointers to the memory partitions. Can be NULL if `num_parts` is zero.

```
void k_mem_domain_add_partition(struct k_mem_domain *domain, struct k_mem_partition
                               *part)
```

Add a memory partition into a memory domain.

Add a memory partition into a memory domain. Partitions must conform to the following constraints:

- Partitions in the same memory domain may not overlap each other.
- Partitions must not be defined which expose private kernel data structures or kernel objects.
- The starting address alignment, and the partition size must conform to the constraints of the underlying memory management hardware, which varies per architecture.
- Memory domain partitions are only intended to control access to memory from user mode threads.
- If `CONFIG_EXECUTE_XOR_WRITE` is enabled, the partition must not allow both writes and execution.

Violating these constraints may lead to CPU exceptions or undefined behavior.

#### Parameters

- `domain` – The memory domain to be added a memory partition.
- `part` – The memory partition to be added

```
void k_mem_domain_remove_partition(struct k_mem_domain *domain, struct k_mem_partition
                                   *part)
```

Remove a memory partition from a memory domain.

Remove a memory partition from a memory domain.

#### Parameters

- `domain` – The memory domain to be removed a memory partition.
- `part` – The memory partition to be removed

```
void k_mem_domain_add_thread(struct k_mem_domain *domain, k_tid_t thread)
```

Add a thread into a memory domain.

Add a thread into a memory domain. It will be removed from whatever memory domain it previously belonged to.

#### Parameters

- `domain` – The memory domain that the thread is going to be added into.
- `thread` – ID of thread going to be added into the memory domain.

## Variables

```
struct k_mem_domain k_mem_domain_default
```

Default memory domain

All threads are a member of some memory domain, even if running in supervisor mode. Threads belong to this default memory domain if they haven't been added to or inherited membership from some other domain.

This memory domain has the `z_libc_partition` partition for the C library added to it if exists.

`struct k_mem_partition`

`#include <mem_domain.h>` Memory Partition.

A memory partition is a region of memory in the linear address space with a specific access policy.

The alignment of the starting address, and the alignment of the size value may have varying requirements based on the capabilities of the underlying memory management hardware; arbitrary values are unlikely to work.

### Public Members

`uintptr_t start`

start address of memory partition

`size_t size`

size of memory partition

`k_mem_partition_attr_t attr`

attribute of memory partition

`struct k_mem_domain`

`#include <mem_domain.h>` Memory Domain.

A memory domain is a collection of memory partitions, used to represent a user thread's access policy for the linear address space. A thread may be a member of only one memory domain, but any memory domain may have multiple threads that are members.

Supervisor threads may also be a member of a memory domain; this has no implications on their memory access but can be useful as any child threads inherit the memory domain membership of the parent.

A user thread belonging to a memory domain with no active partitions will have guaranteed access to its own stack buffer, program text, and read-only data.

### Public Members

`struct k\_mem\_partition partitions[CONFIG_MAX_DOMAIN_PARTITIONS]`

partitions in the domain

`sys\_dlist\_t mem_domain_q`

Doubly linked list of member threads

`uint8_t num_partitions`

number of active partitions in the domain

### 7.30.3 Kernel Objects

A kernel object can be one of three classes of data:

- A core kernel object, such as a semaphore, thread, pipe, etc.
- A thread stack, which is an array of `z_thread_stack_element` and declared with `K_THREAD_STACK_DEFINE()`
- A device driver instance (`const struct device`) that belongs to one of a defined set of subsystems

The set of known kernel objects and driver subsystems is defined in `include/kernel.h` as `k_objects`.

Kernel objects are completely opaque to user threads. User threads work with addresses to kernel objects when making API calls, but may never dereference these addresses, doing so will cause a memory protection fault. All kernel objects must be placed in memory that is not accessible by user threads.

Since user threads may not directly manipulate kernel objects, all use of them must go through system calls. In order to perform a system call on a kernel object, checks are performed by system call handler functions that the kernel object address is valid and that the calling thread has sufficient permissions to work with it.

Permission on an object also has the semantics of a reference to an object. This is significant for certain object APIs which do temporary allocations, or objects which themselves have been allocated from a runtime memory pool.

If an object loses all references, two events may happen:

- If the object has an associated cleanup function, the cleanup function may be called to release any runtime-allocated buffers the object was using.
- If the object itself was dynamically allocated, the memory for the object will be freed.

#### Object Placement

Kernel objects that are only used by supervisor threads have no restrictions and can be located anywhere in the binary, or even declared on stacks. However, to prevent accidental or intentional corruption by user threads, they must not be located in any memory that user threads have direct access to.

In order for a static kernel object to be usable by a user thread via system call APIs, several conditions must be met on how the kernel object is declared:

- The object must be declared as a top-level global at build time, such that it appears in the ELF symbol table. It is permitted to declare kernel objects with static scope. The post-build script [scripts/gen\\_kobject\\_list.py](#) scans the generated ELF file to find kernel objects and places their memory addresses in a special table of kernel object metadata. Kernel objects may be members of arrays or embedded within other data structures.
- Kernel objects must be located in memory reserved for the kernel. They must not be located in any memory partitions that are user-accessible.
- Any memory reserved for a kernel object must be used exclusively for that object. Kernel objects may not be members of a union data type.

Kernel objects that are found but do not meet the above conditions will not be included in the generated table that is used to validate kernel object pointers passed in from user mode.

The debug output of the [scripts/gen\\_kobject\\_list.py](#) script may be useful when debugging why some object was unexpectedly not being tracked. This information will be printed if the script is run with the `--verbose` flag, or if the build system is invoked with verbose output.

## Dynamic Objects

Kernel objects may also be allocated at runtime if `:kconfig: `CONFIG_DYNAMIC_OBJECTS`` is enabled. In this case, the `k_object_alloc()` API may be used to instantiate an object from the calling thread's resource pool. Such allocations may be freed in two ways:

- Supervisor threads may call `k_object_free()` to force a dynamic object to be released.
- If an object's references drop to zero (which happens when no threads have permissions on it) the object will be automatically freed. User threads may drop their own permission on an object with `k_object_release()`, and their permissions are automatically cleared when a thread terminates. Supervisor threads may additionally revoke references for another thread using `k_object_access_revoke()`.

Because permissions are also used for reference counting, it is important for supervisor threads to acquire permissions on objects they are using even though the access control aspects of the permission system are not enforced.

**Implementation Details** The `scripts/gen_kobject_list.py` script is a post-build step which finds all the valid kernel object instances in the binary. It accomplishes this by parsing the DWARF debug information present in the generated ELF file for the kernel.

Any instances of structs or arrays corresponding to kernel objects that meet the object placement criteria will have their memory addresses placed in a special perfect hash table of kernel objects generated by the 'gperf' tool. When a system call is made and the kernel is presented with a memory address of what may or may not be a valid kernel object, the address can be validated with a constant-time lookup in this table.

Drivers are a special case. All drivers are instances of `device`, but it is important to know what subsystem a driver belongs to so that incorrect operations, such as calling a UART API on a sensor driver object, can be prevented. When a device struct is found, its API pointer is examined to determine what subsystem the driver belongs to.

The table itself maps kernel object memory addresses to instances of `z_object`, which has all the meta-data for that object. This includes:

- A bitfield indicating permissions on that object. All threads have a numerical ID assigned to them at build time, used to index the permission bitfield for an object to see if that thread has permission on it. The size of this bitfield is controlled by the `:kconfig: `CONFIG_MAX_THREAD_BYTES`` option and the build system will generate an error if this value is too low.
- A type field indicating what kind of object this is, which is some instance of `k_objects`.
- A set of flags for that object. This is currently used to track initialization state and whether an object is public or not.
- An extra data field. The semantics of this field vary by object type, see the definition of `z_object_data`.

Dynamic objects allocated at runtime are tracked in a runtime red/black tree which is used in parallel to the gperf table when validating object pointers.

## Supervisor Thread Access Permission

Supervisor threads can access any kernel object. However, permissions for supervisor threads are still tracked for two reasons:

- If a supervisor thread calls `k_thread_user_mode_enter()`, the thread will then run in user mode with any permissions it had been granted (in many cases, by itself) when it was a supervisor thread.
- If a supervisor thread creates a user thread with the `K_INHERIT_PERMS` option, the child thread will be granted the same permissions as the parent thread, except the parent thread object.

## User Thread Access Permission

By default, when a user thread is created, it will only have access permissions on its own thread object. Other kernel objects by default are not usable. Access to them needs to be explicitly or implicitly granted. There are several ways to do this.

- If a thread is created with the `K_INHERIT_PERMS`, that thread will inherit all the permissions of the parent thread, except the parent thread object.
- A thread that has permission on an object, or is running in supervisor mode, may grant permission on that object to another thread via the `k_object_access_grant()` API. The convenience pseudo-function `k_thread_access_grant()` may also be used, which accepts an arbitrary number of pointers to kernel objects and calls `k_object_access_grant()` on each of them. The thread being granted permission, or the object whose access is being granted, do not need to be in an initialized state. If the caller is from user mode, the caller must have permissions on both the kernel object and the target thread object.
- Supervisor threads may declare a particular kernel object to be a public object, usable by all current and future threads with the `k_object_access_all_grant()` API. You must assume that any untrusted or exploited code will then be able to access the object. Use this API with caution!
- If a thread was declared statically with `K_THREAD_DEFINE()`, then the `K_THREAD_ACCESS_GRANT()` may be used to grant that thread access to a set of kernel objects at boot time.

Once a thread has been granted access to an object, such access may be removed with the `k_object_access_revoke()` API. This API is not available to user threads, however user threads may use `k_object_release()` to relinquish their own permissions on an object.

API calls from supervisor mode to set permissions on kernel objects that are not being tracked by the kernel will be no-ops. Doing the same from user mode will result in a fatal error for the calling thread.

Objects allocated with `k_object_alloc()` implicitly grant permission on the allocated object to the calling thread.

## Initialization State

Most operations on kernel objects will fail if the object is considered to be in an uninitialized state. The appropriate init function for the object must be performed first.

Some objects will be implicitly initialized at boot:

- Kernel objects that were declared with static initialization macros (such as `K_SEM_DEFINE` for semaphores) will be in an initialized state at build time.
- Device driver objects are considered initialized after their init function is run by the kernel early in the boot process.

If a kernel object is initialized with a private static initializer, the object must have `z_object_init()` called on it at some point by a supervisor thread, otherwise the kernel will consider the object uninitialized if accessed by a user thread. This is very uncommon, typically only for kernel objects that are embedded within some larger struct and initialized statically.

```
struct foo {
    struct k_sem sem;
    ...
};

struct foo my_foo = {
    .sem = Z_SEM_INITIALIZER(my_foo.sem, 0, 1),
    ...
};
```

(continues on next page)

(continued from previous page)

```
...
z_object_init(&my_foo.sem);
...
```

## Creating New Kernel Object Types

When implementing new kernel features or driver subsystems, it may be necessary to define some new kernel object types. There are different steps needed for creating core kernel objects and new driver subsystems.

### Creating New Core Kernel Objects

- In `scripts/gen_kobject_list.py`, add the name of the struct to the `kobjects` list.

Instances of the new struct should now be tracked.

**Creating New Driver Subsystem Kernel Objects** All driver instances are *device*. They are differentiated by what API struct they are set to.

- In `scripts/gen_kobject_list.py`, add the name of the API struct for the new subsystem to the `subsystems` list.

Driver instances of the new subsystem should now be tracked.

## Configuration Options

Related configuration options:

- `:kconfig: `CONFIG_USERSPACE``
- `:kconfig: `CONFIG_MAX_THREAD_BYTES``

## API Reference

*group* `usermode_apis`

### Defines

`K_THREAD_ACCESS_GRANT(name_, ...)`

Grant a static thread access to a list of kernel objects.

For threads declared with `K_THREAD_DEFINE()`, grant the thread access to a set of kernel objects. These objects do not need to be in an initialized state. The permissions will be granted when the threads are initialized in the early boot sequence.

All arguments beyond the first must be pointers to kernel objects.

#### Parameters

- `name_` – Name of the thread, as passed to `K_THREAD_DEFINE()`

`K_OBJ_FLAG_INITIALIZED`

Object initialized

K\_OBJ\_FLAG\_PUBLIC

Object is Public

K\_OBJ\_FLAG\_ALLOC

Object allocated

K\_OBJ\_FLAG\_DRIVER

Driver Object

## Functions

void k\_object\_access\_grant(const void \*object, struct *k\_thread* \*thread)

Grant a thread access to a kernel object

The thread will be granted access to the object if the caller is from supervisor mode, or the caller is from user mode AND has permissions on both the object and the thread whose access is being granted.

### Parameters

- object – Address of kernel object
- thread – Thread to grant access to the object

void k\_object\_access\_revoke(const void \*object, struct *k\_thread* \*thread)

Revoke a thread's access to a kernel object

The thread will lose access to the object if the caller is from supervisor mode, or the caller is from user mode AND has permissions on both the object and the thread whose access is being revoked.

### Parameters

- object – Address of kernel object
- thread – Thread to remove access to the object

void k\_object\_release(const void \*object)

Release an object.

Allows user threads to drop their own permission on an object Their permissions are automatically cleared when a thread terminates.

### Parameters

- object – The object to be released

void k\_object\_access\_all\_grant(const void \*object)

Grant all present and future threads access to an object

If the caller is from supervisor mode, or the caller is from user mode and have sufficient permissions on the object, then that object will have permissions granted to it for *all* current and future threads running in the system, effectively becoming a public kernel object.

Use of this API should be avoided on systems that are running untrusted code as it is possible for such code to derive the addresses of kernel objects and perform unwanted operations on them.

It is not possible to revoke permissions on public objects; once public, any thread may use it.

### Parameters

- object – Address of kernel object

```
void *k_object_alloc(enum k_objects otype)
```

Allocate a kernel object of a designated type

This will instantiate at runtime a kernel object of the specified type, returning a pointer to it. The object will be returned in an uninitialized state, with the calling thread being granted permission on it. The memory for the object will be allocated out of the calling thread's resource pool.

Currently, allocation of thread stacks is not supported.

#### Parameters

- `otype` – Requested kernel object type

**Returns** A pointer to the allocated kernel object, or NULL if memory wasn't available

```
static inline void k_object_free(void *obj)
```

Free an object.

#### Parameters

- `obj` –

## 7.30.4 System Calls

User threads run with a reduced set of privileges than supervisor threads: certain CPU instructions may not be used, and they have access to only a limited part of the memory map. System calls (may) allow user threads to perform operations not directly available to them.

When defining system calls, it is very important to ensure that access to the API's private data is done exclusively through system call interfaces. Private kernel data should never be made available to user mode threads directly. For example, the `k_queue` APIs were intentionally not made available as they store bookkeeping information about the queue directly in the queue buffers which are visible from user mode.

APIs that allow the user to register callback functions that run in supervisor mode should never be exposed as system calls. Reserve these for supervisor-mode access only.

This section describes how to declare new system calls and discusses a few implementation details relevant to them.

### Components

All system calls have the following components:

- A **C prototype** prefixed with `__syscall` for the API. It will be declared in some header under `include/` or in another `SYSCALL_INCLUDE_DIRS` directory. This prototype is never implemented manually, instead it gets created by the [scripts/gen\\_syscalls.py](#) script. What gets generated is an inline function which either calls the implementation function directly (if called from supervisor mode) or goes through privilege elevation and validation steps (if called from user mode).
- An **implementation function**, which is the real implementation of the system call. The implementation function may assume that all parameters passed in have been validated if it was invoked from user mode.
- A **verification function**, which wraps the implementation function and does validation of all the arguments passed in.
- An **unmarshalling function**, which is an automatically generated handler that must be included by user source code.

## C Prototype

The C prototype represents how the API is invoked from either user or supervisor mode. For example, to initialize a semaphore:

```
__syscall void k_sem_init(struct k_sem *sem, unsigned int initial_count,
                        unsigned int limit);
```

The `__syscall` attribute is very special. To the C compiler, it simply expands to `'static inline'`. However to the post-build [scripts/parse\\_syscalls.py](#) script, it indicates that this API is a system call. The [scripts/parse\\_syscalls.py](#) script does some parsing of the function prototype, to determine the data types of its return value and arguments, and has some limitations:

- Array arguments must be passed in as pointers, not arrays. For example, `int foo[]` or `int foo[12]` is not allowed, but should instead be expressed as `int *foo`.
- Function pointers horribly confuse the limited parser. The workaround is to typedef them first, and then express in the argument list in terms of that typedef.
- `__syscall` must be the first thing in the prototype.

The preprocessor is intentionally not used when determining the set of system calls to generate. However, any generated system calls that don't actually have a verification function defined (because the related feature is not enabled in the kernel configuration) will instead point to a special verification for unimplemented system calls. Data type definitions for APIs should not have conditional visibility to the compiler.

Any header file that declares system calls must include a special generated header at the very bottom of the header file. This header follows the naming convention `syscalls/<name of header file>`. For example, at the bottom of `include/sensor.h`:

```
#include <syscalls/sensor.h>
```

C prototype functions must be declared in one of the directories listed in the CMake variable `SYSCALL_INCLUDE_DIRS`. This list always contains `${ZEPHYR_BASE}/include`, but will also contain `APPLICATION_SOURCE_DIR` when `CONFIG_APPLICATION_DEFINED_SYSCALL` is set, or `${ZEPHYR_BASE}/subsys/testsuite/ztest/include` when `CONFIG_ZTEST` is set. Additional paths can be added to the list through the CMake command line or in CMake code that is run before `${ZEPHYR_BASE}/cmake/app/boilerplate.cmake` is run.

**Invocation Context** Source code that uses system call APIs can be made more efficient if it is known that all the code inside a particular C file runs exclusively in user mode, or exclusively in supervisor mode. The system will look for the definition of macros `__ZEPHYR_SUPERVISOR__` or `__ZEPHYR_USER__`, typically these will be added to the compiler flags in the build system for the related files.

- If `:kconfig: 'CONFIG_USERSPACE'` is not enabled, all APIs just directly call the implementation function.
- Otherwise, the default case is to make a runtime check to see if the processor is currently running in user mode, and either make the system call or directly call the implementation function as appropriate.
- If `__ZEPHYR_SUPERVISOR__` is defined, then it is assumed that all the code runs in supervisor mode and all APIs just directly call the implementation function. If the code was actually running in user mode, there will be a CPU exception as soon as it tries to do something it isn't allowed to do.
- If `__ZEPHYR_USER__` is defined, then it is assumed that all the code runs in user mode and system calls are unconditionally made.

**Implementation Details** Declaring an API with `__syscall` causes some code to be generated in C and header files by the [scripts/gen\\_syscalls.py](#) script, all of which can be found in the project out directory under `include/generated/`:

- The system call is added to the enumerated type of system call IDs, which is expressed in `include/generated/syscall_list.h`. It is the name of the API in uppercase, prefixed with `K_SYSCALL_`.
- An entry for the system call is created in the dispatch table `_k_syscall_table`, expressed in `include/generated/syscall_dispatch.c`.
- A weak verification function is declared, which is just an alias of the ‘unimplemented system call’ verifier. This is necessary since the real verification function may or may not be built depending on the kernel configuration. For example, if a user thread makes a sensor subsystem API call, but the sensor subsystem is not enabled, the weak verifier will be invoked instead.
- An unmarshalling function is defined in `include/generated/<name>_mrsh.c`.

The body of the API is created in the generated system header. Using the example of `k_sem_init()`, this API is declared in `include/kernel.h`. At the bottom of `include/kernel.h` is:

```
#include <syscalls/kernel.h>
```

Inside this header is the body of `k_sem_init()`:

```
static inline void k_sem_init(struct k_sem * sem, unsigned int initial_count,
↪ unsigned int limit)
{
    #ifdef CONFIG_USERSPACE
        if (z_syscall_trap()) {
            arch_syscall_invoke3(*(uintptr_t *)&sem, *(uintptr_t *)&initial_count,
↪ *(uintptr_t *)&limit, K_SYSCALL_K_SEM_INIT);
            return;
        }
        compiler_barrier();
    #endif
    z_impl_k_sem_init(sem, initial_count, limit);
}
```

This generates an inline function that takes three arguments with void return value. Depending on context it will either directly call the implementation function or go through a system call elevation. A prototype for the implementation function is also automatically generated.

The final layer is the invocation of the system call itself. All architectures implementing system calls must implement the seven inline functions `_arch_syscall_invoke0()` through `_arch_syscall_invoke6()`. These functions marshal arguments into designated CPU registers and perform the necessary privilege elevation. Parameters of API inline function, before being passed as arguments to system call, are C casted to `uintptr_t` which matches size of register. Exception to above is passing 64-bit parameters on 32-bit systems, in which case 64-bit parameters are split into lower and higher part and passed as two consecutive arguments. There is always a `uintptr_t` type return value, which may be neglected if not needed.

Some system calls may have more than six arguments, but number of arguments passed via registers is limited to six for all architectures. Additional arguments will need to be passed in an array in the source memory space, which needs to be treated as untrusted memory in the verification function. This code (packing, unpacking and validation) is generated automatically as needed in the stub above and in the unmarshalling function.

System calls return `uintptr_t` type value that is C casted, by wrapper, to a return type of API prototype declaration. This means that 64-bit value may not be directly returned, from a system call to its wrapper, on 32-bit systems. To solve the problem the automatically generated wrapper function defines 64-bit intermediate variable, which is considered **untrusted** buffer, on its stack and passes pointer to that variable to the system call, as a final argument. Upon return from the system call the value written to that buffer will be returned by the wrapper function. The problem does not exist on 64-bit systems which are able to return 64-bit values directly.

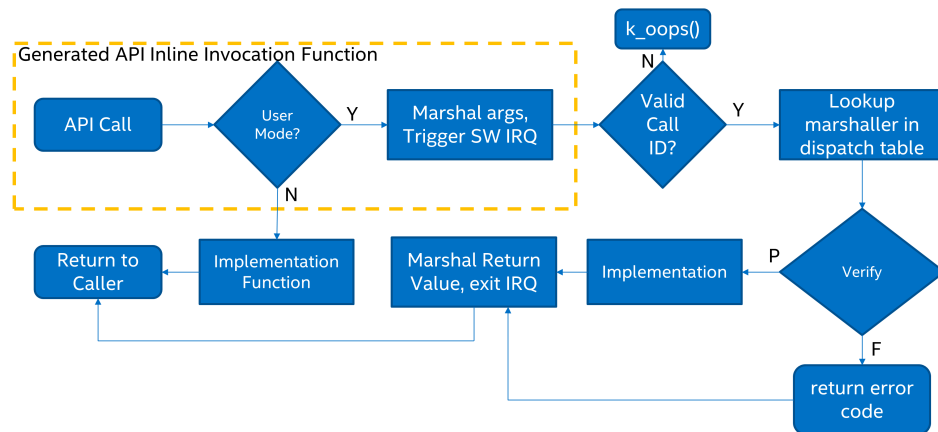

Fig. 10: System Call execution flow

### Implementation Function

The implementation function is what actually does the work for the API. Zephyr normally does little to no error checking of arguments, or does this kind of checking with assertions. When writing the implementation function, validation of any parameters is optional and should be done with assertions.

All implementation functions must follow the naming convention, which is the name of the API prefixed with `z_impl_`. Implementation functions may be declared in the same header as the API as a static inline function or declared in some C file. There is no prototype needed for implementation functions, these are automatically generated.

### Verification Function

The verification function runs on the kernel side when a user thread makes a system call. When the user thread makes a software interrupt to elevate to supervisor mode, the common system call entry point uses the system call ID provided by the user to look up the appropriate unmarshalling function for that system call and jump into it. This in turn calls the verification function.

Verification and unmarshalling functions only run when system call APIs are invoked from user mode. If an API is invoked from supervisor mode, the implementation is simply called and there is no software trap.

The purpose of the verification function is to validate all the arguments passed in. This includes:

- Any kernel object pointers provided. For example, the semaphore APIs must ensure that the semaphore object passed in is a valid semaphore and that the calling thread has permission on it.
- Any memory buffers passed in from user mode. Checks must be made that the calling thread has read or write permissions on the provided buffer.
- Any other arguments that have a limited range of valid values.

Verification functions involve a great deal of boilerplate code which has been made simpler by some macros in `include/syscall_handler.h`. Verification functions should be declared using these macros.

**Argument Validation** Several macros exist to validate arguments:

- `Z_SYSCALL_OBJ()` Checks a memory address to assert that it is a valid kernel object of the expected type, that the calling thread has permissions on it, and that the object is initialized.
- `Z_SYSCALL_OBJ_INIT()` is the same as `Z_SYSCALL_OBJ()`, except that the provided object may be uninitialized. This is useful for verifiers of object init functions.

- `Z_SYSCALL_OBJ_NEVER_INIT()` is the same as `Z_SYSCALL_OBJ()`, except that the provided object must be uninitialized. This is not used very often, currently only for `k_thread_create()`.
- `Z_SYSCALL_MEMORY_READ()` validates a memory buffer of a particular size. The calling thread must have read permissions on the entire buffer.
- `Z_SYSCALL_MEMORY_WRITE()` is the same as `Z_SYSCALL_MEMORY_READ()` but the calling thread must additionally have write permissions.
- `Z_SYSCALL_MEMORY_ARRAY_READ()` validates an array whose total size is expressed as separate arguments for the number of elements and the element size. This macro correctly accounts for multiplication overflow when computing the total size. The calling thread must have read permissions on the total size.
- `Z_SYSCALL_MEMORY_ARRAY_WRITE()` is the same as `Z_SYSCALL_MEMORY_ARRAY_READ()` but the calling thread must additionally have write permissions.
- `Z_SYSCALL_VERIFY_MSG()` does a runtime check of some boolean expression which must evaluate to true otherwise the check will fail. A variant `Z_SYSCALL_VERIFY` exists which does not take a message parameter, instead printing the expression tested if it fails. The latter should only be used for the most obvious of tests.
- `Z_SYSCALL_DRIVER_OP()` checks at runtime if a driver instance is capable of performing a particular operation. While this macro can be used by itself, it's mostly a building block for macros that are automatically generated for every driver subsystem. For instance, to validate the GPIO driver, one could use the `Z_SYSCALL_DRIVER_GPIO()` macro.
- `Z_SYSCALL_SPECIFIC_DRIVER()` is a runtime check to verify that a provided pointer is a valid instance of a specific device driver, that the calling thread has permissions on it, and that the driver has been initialized. It does this by checking the API structure pointer that is stored within the driver instance and ensuring that it matches the provided value, which should be the address of the specific driver's API structure.

If any check fails, the macros will return a nonzero value. The macro `Z_OOPS()` can be used to induce a kernel oops which will kill the calling thread. This is done instead of returning some error condition to keep the APIs the same when calling from supervisor mode.

**Verifier Definition** All system calls are dispatched to a verifier function with a prefixed `z_vrfy_` name based on the system call. They have exactly the same return type and argument types as the wrapped system call. Their job is to execute the system call (generally by calling the implementation function) after having validated all arguments.

The verifier is itself invoked by an automatically generated unmarshaller function which takes care of unpacking the register arguments from the architecture layer and casting them to the correct type. This is defined in a header file that must be included from user code, generally somewhere after the definition of the verifier in a translation unit (so that it can be inlined).

For example:

```
static int z_vrfy_k_sem_take(struct k_sem *sem, int32_t timeout)
{
    Z_OOPS(Z_SYSCALL_OBJ(sem, K_OBJ_SEM));
    return z_impl_k_sem_take(sem, timeout);
}
#include <syscalls/k_sem_take_mrrh.c>
```

**Verification Memory Access Policies** Parameters passed to system calls by reference require special handling, because the value of these parameters can be changed at any time by any user thread that has access to the memory that parameter points to. If the kernel makes any logical decisions based on the contents of this memory, this can open up the kernel to attacks even if checking is done. This is a class of exploits known as TOCTOU (Time Of Check to Time Of Use).

The proper procedure to mitigate these attacks is to make a copies in the verification function, and only perform parameter checks on the copies, which user threads will never have access to. The implementation functions get passed the copy and not the original data sent by the user. The `z_user_to_copy()` and `z_user_from_copy()` APIs exist for this purpose.

There is one exception in place, with respect to large data buffers which are only used to provide a memory area that is either only written to, or whose contents are never used for any validation or control flow. Further discussion of this later in this section.

As a first example, consider a parameter which is used as an output parameter for some integral value:

```
int z_vrfy_some_syscall(int *out_param)
{
    int local_out_param;
    int ret;

    ret = z_impl_some_syscall(&local_out_param);
    Z_OOPS(z_user_to_copy(out_param, &local_out_param, sizeof(*out_param)));
    return ret;
}
```

Here we have allocated `local_out_param` on the stack, passed its address to the implementation function, and then used `z_user_to_copy()` to fill in the memory passed in by the caller.

It might be tempting to do something more concise:

```
int z_vrfy_some_syscall(int *out_param)
{
    Z_OOPS(Z_SYSCALL_MEMORY_WRITE(out_param, sizeof(*out_param)));
    return z_impl_some_syscall(out_param);
}
```

However, this is unsafe if the implementation ever does any reads to this memory as part of its logic. For example, it could be used to store some counter value, and this could be meddled with by user threads that have access to its memory. It is by far safest for small integral values to do the copying as shown in the first example.

Some parameters may be input/output. For instance, it's not uncommon to see APIs which pass in a pointer to some `size_t` which is a maximum allowable size, which is then updated by the implementation to reflect the actual number of bytes processed. This too should use a stack copy:

```
int z_vrfy_in_out_syscall(size_t *size_ptr)
{
    size_t size;
    int ret;

    Z_OOPS(z_user_from_copy(&size, size_ptr, sizeof(size)));
    ret = z_impl_in_out_syscall(&size);
    *size_ptr = size;
    return ret;
}
```

Many system calls pass in structures or even linked data structures. All should be copied. Typically this is done by allocating copies on the stack:

```
struct bar {
    ...
};

struct foo {
```

(continues on next page)

(continued from previous page)

```

...
struct bar *bar_left;
struct bar *bar_right;
};

int z_vrfy_must_alloc(struct foo *foo)
{
    int ret;
    struct foo foo_copy;
    struct bar bar_right_copy;
    struct bar bar_left_copy;

    Z_OOPS(z_user_from_copy(&foo_copy, foo, sizeof(*foo)));
    Z_OOPS(z_user_from_copy(&bar_right_copy, foo_copy.bar_right,
                          sizeof(struct bar)));
    foo_copy.bar_right = &bar_right_copy;
    Z_OOPS(z_user_from_copy(&bar_left_copy, foo_copy.bar_left,
                          sizeof(struct bar)));
    foo_copy.bar_left = &bar_left_copy;

    return z_impl_must_alloc(&foo_copy);
}

```

In some cases the amount of data isn't known at compile time or may be too large to allocate on the stack. In this scenario, it may be necessary to draw memory from the caller's resource pool via `z_thread_malloc()`. This should always be considered last resort. Functional safety programming guidelines heavily discourage usage of heap and the fact that a resource pool is used must be clearly documented. Any issues with allocation must be reported, to a caller, with returning the `-ENOMEM`. The `Z_OOPS()` should never be used to verify if resource allocation has been successful.

```

struct bar {
    ...
};

struct foo {
    size_t count;
    struct bar *bar_list; /* array of struct bar of size count */
};

int z_vrfy_must_alloc(struct foo *foo)
{
    int ret;
    struct foo foo_copy;
    struct bar *bar_list_copy;
    size_t bar_list_bytes;

    /* Safely copy foo into foo_copy */
    Z_OOPS(z_user_from_copy(&foo_copy, foo, sizeof(*foo)));

    /* Bounds check the count member, in the copy we made */
    if (foo_copy.count > 32) {
        return -EINVAL;
    }

    /* Allocate RAM for the bar_list, replace the pointer in
     * foo_copy */

```

(continues on next page)

(continued from previous page)

```

bar_list_bytes = foo_copy.count * sizeof(struct_bar);
bar_list_copy = z_thread_malloc(bar_list_bytes);
if (bar_list_copy == NULL) {
    return -ENOMEM;
}
Z_OOPS(z_user_from_copy(bar_list_copy, foo_copy.bar_list,
                        bar_list_bytes));
foo_copy.bar_list = bar_list_copy;

ret = z_impl_must_alloc(&foo_copy);

/* All done with the memory, free it and return */
k_free(foo_copy.bar_list_copy);
return ret;
}

```

Finally, we must consider large data buffers. These represent areas of user memory which either have data copied out of, or copied into. It is permitted to pass these pointers to the implementation function directly. The caller's access to the buffer still must be validated with Z\_SYSCALL\_MEMORY APIs. The following constraints need to be met:

- If the buffer is used by the implementation function to write data, such as data captured from some MMIO region, the implementation function must only write this data, and never read it.
- If the buffer is used by the implementation function to read data, such as a block of memory to write to some hardware destination, this data must be read without any processing. No conditional logic can be implemented due to the data buffer's contents. If such logic is required a copy must be made.
- The buffer must only be used synchronously with the call. The implementation must not ever save the buffer address and use it asynchronously, such as when an interrupt fires.

```

int z_vrfy_get_data_from_kernel(void *buf, size_t size)
{
    Z_OOPS(Z_SYSCALL_MEMORY_WRITE(buf, size));
    return z_impl_get_data_from_kernel(buf, size);
}

```

**Verification Return Value Policies** When verifying system calls, it's important to note which kinds of verification failures should propagate a return value to the caller, and which should simply invoke Z\_OOPS() which kills the calling thread. The current conventions are as follows:

1. For system calls that are defined but not compiled, invocations of these missing system calls are routed to handler\_no\_syscall() which invokes Z\_OOPS().
2. Any invalid access to memory found by the set of Z\_SYSCALL\_MEMORY APIs, z\_user\_from\_copy(), z\_user\_to\_copy() should trigger a Z\_OOPS. This happens when the caller doesn't have appropriate permissions on the memory buffer or some size calculation overflowed.
3. Most system calls take kernel object pointers as an argument, checked either with one of the Z\_SYSCALL\_OBJ functions, Z\_SYSCALL\_DRIVER\_nnnnn, or manually using z\_object\_validate(). These can fail for a variety of reasons: missing driver API, bad kernel object pointer, wrong kernel object type, or improper initialization state. These issues should always invoke Z\_OOPS().
4. Any error resulting from a failed memory heap allocation, often from invoking z\_thread\_malloc(), should propagate -ENOMEM to the caller.
5. General parameter checks should be done in the implementation function, in most cases using CHECKIF().

- The behavior of `CHECKIF()` depends on the kernel configuration, but if user mode is enabled, `:kconfig: `CONFIG_RUNTIME_ERROR_CHECKS`` is enforced, which guarantees that these checks will be made and a return value propagated.
6. It is totally forbidden for any kind of kernel mode callback function to be registered from user mode. APIs which simply install callbacks shall not be exposed as system calls. Some driver subsystem APIs may take optional function callback pointers. User mode verification functions for these APIs must enforce that these are NULL and should invoke `Z_OOPS()` if not.
  7. Some parameter checks are enforced only from user mode. These should be checked in the verification function and propagate a return value to the caller if possible.

There are some known exceptions to these policies currently in Zephyr:

- `k_thread_join()` and `k_thread_abort()` are no-ops if the thread object isn't initialized. This is because for threads, the initialization bit pulls double-duty to indicate whether a thread is running, cleared upon exit. See #23030.
- `k_thread_create()` invokes `Z_OOPS()` for parameter checks, due to a great deal of existing code ignoring the return value. This will also be addressed by #23030.
- `k_thread_abort()` invokes `Z_OOPS()` if an essential thread is aborted, as the function has no return value.
- Various system calls related to logging invoke `Z_OOPS()` when bad parameters are passed in as they do not propagate errors.

## Configuration Options

Related configuration options:

- `:kconfig: `CONFIG_USERSPACE``

## APIs

Helper macros for creating system call verification functions are provided in `include/syscall_handler.h`:

- `Z_SYSCALL_OBJ()`
- `Z_SYSCALL_OBJ_INIT()`
- `Z_SYSCALL_OBJ_NEVER_INIT()`
- `Z_OOPS()`
- `Z_SYSCALL_MEMORY_READ()`
- `Z_SYSCALL_MEMORY_WRITE()`
- `Z_SYSCALL_MEMORY_ARRAY_READ()`
- `Z_SYSCALL_MEMORY_ARRAY_WRITE()`
- `Z_SYSCALL_VERIFY_MSG()`
- `Z_SYSCALL_VERIFY`

Functions for invoking system calls are defined in `include/syscall.h`:

- `_arch_syscall_invoke0()`
- `_arch_syscall_invoke1()`
- `_arch_syscall_invoke2()`
- `_arch_syscall_invoke3()`
- `_arch_syscall_invoke4()`

- `_arch_syscall_invoke5()`
- `_arch_syscall_invoke6()`

### 7.30.5 MPU Stack Objects

#### Thread Stack Creation

Thread stacks are declared statically with `K_THREAD_STACK_DEFINE()` or embedded within structures using `K_THREAD_STACK_MEMBER()`

For architectures which utilize memory protection unit (MPU) hardware, stacks are physically contiguous allocations. This contiguous allocation has implications for the placement of stacks in memory, as well as the implementation of other features such as stack protection and userspace. The implications for placement are directly attributed to the alignment requirements for MPU regions. This is discussed in the memory placement section below.

#### Stack Guards

Stack protection mechanisms require hardware support that can restrict access to memory. Memory protection units can provide this kind of support. The MPU provides a fixed number of regions. Each region contains information about the start, end, size, and access attributes to be enforced on that particular region.

Stack guards are implemented by using a single MPU region and setting the attributes for that region to not allow write access. If invalid accesses occur, a fault ensues. The stack guard is defined at the bottom (the lowest address) of the stack.

#### Memory Placement

During stack creation, a set of constraints are enforced on the allocation of memory. These constraints include determining the alignment of the stack and the correct sizing of the stack. During linking of the binary, these constraints are used to place the stacks properly.

The main source of the memory constraints is the MPU design for the SoC. The MPU design may require specific constraints on the region definition. These can include alignment of beginning and end addresses, sizes of allocations, or even interactions between overlapping regions.

Some MPUs require that each region be aligned to a power of two. These SoCs will have **:kconfig: CONFIG\_MPU\_REQUIRES\_POWER\_OF\_TWO\_ALIGNMENT** defined. This means that a 1500 byte stack should be aligned to a 2kB boundary and the stack size should also be adjusted to 2kB to ensure that nothing else is placed in the remainder of the region. SoCs which include the unmodified ARM v7m MPU will have these constraints.

Some ARM MPUs use start and end addresses to define MPU regions and both the start and end addresses require 32 byte alignment. An example of this kind of MPU is found in the NXP FRDM K64F.

MPUs may have a region priority mechanisms that use the highest priority region that covers the memory access to determine the enforcement policy. Others may logically OR regions to determine enforcement policy.

Size and alignment constraints may result in stack allocations being larger than the requested size. Region priority mechanisms may result in some added complexity when implementing stack guards.

### 7.30.6 MPU Backed Userspace

The MPU backed userspace implementation requires the creation of a secondary set of stacks. These stacks exist in a 1:1 relationship with each thread stack defined in the system. The privileged stacks are created as a part of the build process.

A post-build script [scripts/gen\\_kobject\\_list.py](#) scans the generated ELF file and finds all of the thread stack objects. A set of privileged stacks, a lookup table, and a set of helper functions are created and added to the image.

During the process of dropping a thread to user mode, the privileged stack information is filled in and later used by the swap and system call infrastructure to configure the MPU regions properly for the thread stack and guard (if applicable).

During system calls, the user mode thread's access to the system call and the passed-in parameters are all validated. The user mode thread is then elevated to privileged mode, the stack is switched to use the privileged stack, and the call is made to the specified kernel API. On return from the kernel API, the thread is set back to user mode and the stack is restored to the user stack.

## 7.31 Utilities

This page contains reference documentation for `<sys/util.h>`, which provides miscellaneous utility functions and macros.

*group sys-util*

### Defines

`POINTER_TO_UINT(x)`

Cast `x`, a pointer, to an unsigned integer.

`UINT_TO_POINTER(x)`

Cast `x`, an unsigned integer, to a `void*`.

`POINTER_TO_INT(x)`

Cast `x`, a pointer, to a signed integer.

`INT_TO_POINTER(x)`

Cast `x`, a signed integer, to a `void*`.

`BITS_PER_LONG`

Number of bits in a long int.

`GENMASK(h, l)`

Create a contiguous bitmask starting at bit position `l` and ending at position `h`.

`ZERO_OR_COMPILE_ERROR(cond)`

0 if `cond` is true-ish; causes a compile error otherwise.

`IS_ARRAY(array)`

Zero if `array` has an array type, a compile error otherwise.

This macro is available only from C, not C++.

**ARRAY\_SIZE(array)**

Number of elements in the given array.

In C++, due to language limitations, this will accept as array any type that implements operator []. The results may not be particularly meaningful in this case.

In C, passing a pointer as array causes a compile error.

**PART\_OF\_ARRAY(array, ptr)**

Check if a pointer ptr lies within array.

In C but not C++, this causes a compile error if array is not an array (e.g. if ptr and array are mixed up).

**Parameters**

- ptr – a pointer
- array – an array

**Returns** 1 if ptr is part of array, 0 otherwise

**CONTAINER\_OF(ptr, type, field)**

Get a pointer to a container structure from an element.

Example:

```
struct foo {  
    int bar;  
};  
  
struct foo my_foo;  
int *ptr = &my_foo.bar;  
  
struct foo *container = CONTAINER_OF(ptr, struct foo, bar);
```

Above, container points at my\_foo.

**Parameters**

- ptr – pointer to a structure element
- type – name of the type that ptr is an element of
- field – the name of the field within the struct ptr points to

**Returns** a pointer to the structure that contains ptr

**ROUND\_UP(x, align)**

Value of x rounded up to the next multiple of align, which must be a power of 2.

**ROUND\_DOWN(x, align)**

Value of x rounded down to the previous multiple of align, which must be a power of 2.

**WB\_UP(x)**

Value of x rounded up to the next word boundary.

**WB\_DN(x)**

Value of x rounded down to the previous word boundary.

**ceiling\_fraction(numerator, divider)**

Ceiling function applied to numerator / divider as a fraction.

MAX(a, b)

The larger value between a and b.

---

**Note:** Arguments are evaluated twice.

---

MIN(a, b)

The smaller value between a and b.

---

**Note:** Arguments are evaluated twice.

---

CLAMP(val, low, high)

Clamp a value to a given range.

---

**Note:** Arguments are evaluated multiple times.

---

KB(x)

Number of bytes in x kibibytes.

MB(x)

Number of bytes in x mebibytes.

GB(x)

Number of bytes in x gibibytes.

KHZ(x)

Number of Hz in x kHz.

MHZ(x)

Number of Hz in x MHz.

BIT(n)

Unsigned integer with bit position n set (signed in assembly language).

BIT64(\_n)

64-bit unsigned integer with bit position \_n set.

WRITE\_BIT(var, bit, set)

Set or clear a bit depending on a boolean value.

The argument var is a variable whose value is written to as a side effect.

**Parameters**

- var – Variable to be altered
- bit – Bit number
- set – if 0, clears bit in var; any other value sets bit

BIT\_MASK(n)

Bit mask with bits 0 through n-1 (inclusive) set, or 0 if n is 0.

BIT64\_MASK(n)

64-bit bit mask with bits 0 through n-1 (inclusive) set, or 0 if n is 0.

IS\_ENABLED(config\_macro)

Check for macro definition in compiler-visible expressions.

This trick was pioneered in Linux as the config\_enabled() macro. It has the effect of taking a macro value that may be defined to “1” or may not be defined at all and turning it into a

literal expression that can be handled by the C compiler instead of just the preprocessor. It is often used with a `CONFIG_FOO` macro which may be defined to 1 via Kconfig, or left undefined.

That is, it works similarly to `#if defined(CONFIG_FOO)` except that its expansion is a C expression. Thus, much `#ifdef` usage can be replaced with equivalents like:

```
if (IS_ENABLED(CONFIG_FOO)) {
    do_something_with_foo
}
```

This is cleaner since the compiler can generate errors and warnings for `do_something_with_foo` even when `CONFIG_FOO` is undefined.

#### Parameters

- `config_macro` – Macro to check

**Returns** 1 if `config_macro` is defined to 1, 0 otherwise (including if `config_macro` is not defined)

`COND_CODE_1(_flag, _if_1_code, _else_code)`

Insert code depending on whether `_flag` expands to 1 or not.

This relies on similar tricks as [IS\\_ENABLED\(\)](#), but as the result of `_flag` expansion, results in either `_if_1_code` or `_else_code` is expanded.

To prevent the preprocessor from treating commas as argument separators, the `_if_1_code` and `_else_code` expressions must be inside brackets/parentheses: `()`. These are stripped away during macro expansion.

Example:

```
COND_CODE_1(CONFIG_FLAG, (uint32_t x;), (there_is_no_flag();))
```

If `CONFIG_FLAG` is defined to 1, this expands to:

```
uint32_t x;
```

It expands to `there_is_no_flag();` otherwise.

This could be used as an alternative to:

```
#if defined(CONFIG_FLAG) && (CONFIG_FLAG == 1)
#define MAYBE_DECLARE(x) uint32_t x
#else
#define MAYBE_DECLARE(x) there_is_no_flag()
#endif

MAYBE_DECLARE(x);
```

However, the advantage of [COND\\_CODE\\_1\(\)](#) is that code is resolved in place where it is used, while the `#if` method defines `MAYBE_DECLARE` on two lines and requires it to be invoked again on a separate line. This makes [COND\\_CODE\\_1\(\)](#) more concise and also sometimes more useful when used within another macro's expansion.

---

**Note:** `_flag` can be the result of preprocessor expansion, e.g. an expression involving [NUM\\_VA\\_ARGS\\_LESS\\_1\(...\)](#). However, `_if_1_code` is only expanded if `_flag` expands to the integer literal 1. Integer expressions that evaluate to 1, e.g. after doing some arithmetic, will not work.

---

#### Parameters

- `_flag` – evaluated flag
- `_if_1_code` – result if `_flag` expands to 1; must be in parentheses
- `_else_code` – result otherwise; must be in parentheses

`COND_CODE_0(_flag, _if_0_code, _else_code)`

Like [COND\\_CODE\\_1\(\)](#) except tests if `_flag` is 0.

This is like [COND\\_CODE\\_1\(\)](#), except that it tests whether `_flag` expands to the integer literal 0. It expands to `_if_0_code` if so, and `_else_code` otherwise; both of these must be enclosed in parentheses.

**See also:**

[COND\\_CODE\\_1\(\)](#)

#### Parameters

- `_flag` – evaluated flag
- `_if_0_code` – result if `_flag` expands to 0; must be in parentheses
- `_else_code` – result otherwise; must be in parentheses

`IF_ENABLED(_flag, _code)`

Insert code if `_flag` is defined and equals 1.

Like [COND\\_CODE\\_1\(\)](#), this expands to `_code` if `_flag` is defined to 1; it expands to nothing otherwise.

Example:

```
IF_ENABLED(CONFIG_FLAG, (uint32_t foo;))
```

If `CONFIG_FLAG` is defined to 1, this expands to:

```
uint32_t foo;
```

and to nothing otherwise.

It can be considered as a more compact alternative to:

```
#if defined(CONFIG_FLAG) && (CONFIG_FLAG == 1)
uint32_t foo;
#endif
```

#### Parameters

- `_flag` – evaluated flag
- `_code` – result if `_flag` expands to 1; must be in parentheses

`IS_EMPTY(a)`

Check if a macro has a replacement expression.

If `a` is a macro defined to a nonempty value, this will return true, otherwise it will return false. It only works with defined macros, so an additional `#ifdef` test may be needed in some cases.

This macro may be used with [COND\\_CODE\\_1\(\)](#) and [COND\\_CODE\\_0\(\)](#) while processing to avoid processing empty arguments.

Note that this macro is intended to check macro names that evaluate to replacement lists being empty or containing numbers or macro name like tokens.

Example:

```
#define EMPTY
#define NON_EMPTY 1
#undef UNDEFINED
IS_EMPTY(EMPTY)
IS_EMPTY(NON_EMPTY)
IS_EMPTY(UNDEFINED)
#if defined(EMPTY) && IS_EMPTY(EMPTY) == true
some_conditional_code
#endif
```

In above examples, the invocations of `IS_EMPTY(...)` return true, false, and true; `some_conditional_code` is included.

---

**Note:** Not all arguments are accepted by this macro and compilation will fail if argument cannot be concatenated with literal constant. That will happen if argument does not start with letter or number. Example arguments that will fail during compilation: `.arg`, `(arg)`, `"arg"`, `{arg}`.

---

### Parameters

- `a` – macro to check for emptiness

`LIST_DROP_EMPTY(...)`

Remove empty arguments from list.

During macro expansion, and other preprocessor generated lists may contain empty elements, e.g.:

```
#define LIST ,a,b,,d,
```

Using `EMPTY` to show each empty element, `LIST` contains:

```
EMPTY, a, b, EMPTY, d
```

When processing such lists, e.g. using `FOR_EACH()`, all empty elements will be processed, and may require filtering out. To make that process easier, it is enough to invoke `LIST_DROP_EMPTY` which will remove all empty elements.

Example:

```
LIST_DROP_EMPTY(LIST)
```

expands to:

```
a, b, d
```

### Parameters

- `...` – list to be processed

`EMPTY`

Macro with an empty expansion.

This trivial definition is provided for readability when a macro should expand to an empty result, which e.g. is sometimes needed to silence checkpatch.

Example:

```
#define LIST_ITEM(n) , item##n
```

The above would cause checkpatch to complain, but:

```
#define LIST_ITEM(n) EMPTY, item##n
```

would not.

IDENTITY(V)

Macro that expands to its argument.

This is useful in macros like `FOR_EACH()` when there is no transformation required on the list elements.

**Parameters**

- V – any value

GET\_ARG\_N(N, ...)

Get nth argument from argument list.

**Parameters**

- N – Argument index to fetch. Counter from 1.
- ... – Variable list of arguments from which one argument is returned.

**Returns** Nth argument.

GET\_ARGS\_LESS\_N(N, ...)

Strips n first arguments from the argument list.

**Parameters**

- N – Number of arguments to discard.
- ... – Variable list of arguments.

**Returns** argument list without N first arguments.

UTIL\_OR(a, b)

Like `a || b`, but does evaluation and short-circuiting at C preprocessor time.

This is not the same as the binary `||` operator; in particular, `a` should expand to an integer literal 0 or 1. However, `b` can be any value.

This can be useful when `b` is an expression that would cause a build error when `a` is 1.

UTIL\_AND(a, b)

Like `a && b`, but does evaluation and short-circuiting at C preprocessor time.

This is not the same as the binary `&&`, however; in particular, `a` should expand to an integer literal 0 or 1. However, `b` can be any value.

This can be useful when `b` is an expression that would cause a build error when `a` is 0.

UTIL\_LISTIFY(LEN, F, ...)

Generates a sequence of code.

Example:

```
#define FOO(i, _) MY_PWM ## i ,  
{ UTIL_LISTIFY(PWM_COUNT, FOO) }
```

The above two lines expand to:

```
{ MY_PWM0 , MY_PWM1 , }
```

---

**Note:** Calling UTIL\_LISTIFY with undefined arguments has undefined behavior.

---

### Parameters

- **LEN** – The length of the sequence. Must be an integer literal less than 255.
- **F** – A macro function that accepts at least two arguments: `F(i, ...)`. `F` is called repeatedly in the expansion. Its first argument `i` is the index in the sequence, and the variable list of arguments passed to `UTIL_LISTIFY` are passed through to `F`.

`FOR_EACH(F, sep, ...)`

Call a macro `F` on each provided argument with a given separator between each call.

Example:

```
#define F(x) int a##x
FOR_EACH(F, (;), 4, 5, 6);
```

This expands to:

```
int a4;
int a5;
int a6;
```

### Parameters

- **F** – Macro to invoke
- **sep** – Separator (e.g. comma or semicolon). Must be in parentheses; this is required to enable providing a comma as separator.
- **...** – Variable argument list. The macro `F` is invoked as `F(element)` for each element in the list.

`FOR_EACH_NONEMPTY_TERM(F, term, ...)`

Like `FOR_EACH()`, but with a terminator instead of a separator, and drops empty elements from the argument list.

The `sep` argument to `FOR_EACH(F, (sep), a, b)` is a separator which is placed between calls to `F`, like this:

```
FOR_EACH(F, (sep), a, b) // F(a) sep F(b)
                        //          ^^^ no sep here!
```

By contrast, the `term` argument to `FOR_EACH_NONEMPTY_TERM(F, (term), a, b)` is added after each time `F` appears in the expansion:

```
FOR_EACH_NONEMPTY_TERM(F, (term), a, b) // F(a) term F(b) term
                                         //          ^^^^
```

Further, any empty elements are dropped:

```
FOR_EACH_NONEMPTY_TERM(F, (term), a, EMPTY, b) // F(a) term F(b) term
```

This is more convenient in some cases, because `FOR_EACH_NONEMPTY_TERM()` expands to nothing when given an empty argument list, and it's often cumbersome to write a macro `F` that does the right thing even when given an empty argument.

One example is when `my_array` may or may not be empty, and the results are embedded in a larger initializer:

```
#define SQUARE(x) ((x)*(x))

int my_array[] = {
    FOR_EACH_NONEMPTY_TERM(SQUARE, (,), FOO(...))
    FOR_EACH_NONEMPTY_TERM(SQUARE, (,), BAR(...))
    FOR_EACH_NONEMPTY_TERM(SQUARE, (,), BAZ(...))
};
```

This is more convenient than:

- a. figuring out whether the `FOO`, `BAR`, and `BAZ` expansions are empty and adding a comma manually (or not) between `FOR_EACH()` calls
- b. rewriting `SQUARE` so it reacts appropriately when “`x`” is empty (which would be necessary if e.g. `FOO` expands to nothing)

#### Parameters

- `F` – Macro to invoke on each nonempty element of the variable arguments
- `term` – Terminator (e.g. comma or semicolon) placed after each invocation of `F`. Must be in parentheses; this is required to enable providing a comma as separator.
- `...` – Variable argument list. The macro `F` is invoked as `F(element)` for each nonempty element in the list.

`FOR_EACH_IDX(F, sep, ...)`

Call macro `F` on each provided argument, with the argument's index as an additional parameter.

This is like `FOR_EACH()`, except `F` should be a macro which takes two arguments: `F(index, variable_arg)`.

Example:

```
#define F(idx, x) int a##idx = x
FOR_EACH_IDX(F, (;), 4, 5, 6);
```

This expands to:

```
int a0 = 4;
int a1 = 5;
int a2 = 6;
```

#### Parameters

- `F` – Macro to invoke
- `sep` – Separator (e.g. comma or semicolon). Must be in parentheses; this is required to enable providing a comma as separator.
- `...` – Variable argument list. The macro `F` is invoked as `F(index, element)` for each element in the list.

FOR\_EACH\_FIXED\_ARG(F, sep, fixed\_arg, ...)

Call macro F on each provided argument, with an additional fixed argument as a parameter.

This is like [FOR\\_EACH\(\)](#), except F should be a macro which takes two arguments: F(variable\_arg, fixed\_arg).

Example:

```
static void func(int val, void *dev);
FOR_EACH_FIXED_ARG(func, (;), dev, 4, 5, 6);
```

This expands to:

```
func(4, dev);
func(5, dev);
func(6, dev);
```

#### Parameters

- F – Macro to invoke
- sep – Separator (e.g. comma or semicolon). Must be in parentheses; this is required to enable providing a comma as separator.
- fixed\_arg – Fixed argument passed to F as the second macro parameter.
- ... – Variable argument list. The macro F is invoked as F(element, fixed\_arg) for each element in the list.

FOR\_EACH\_IDX\_FIXED\_ARG(F, sep, fixed\_arg, ...)

Calls macro F for each variable argument with an index and fixed argument.

This is like the combination of [FOR\\_EACH\\_IDX\(\)](#) with [FOR\\_EACH\\_FIXED\\_ARG\(\)](#).

Example:

```
#define F(idx, x, fixed_arg) int fixed_arg##idx = x
FOR_EACH_IDX_FIXED_ARG(F, (;), a, 4, 5, 6);
```

This expands to:

```
int a0 = 4;
int a1 = 5;
int a2 = 6;
```

#### Parameters

- F – Macro to invoke
- sep – Separator (e.g. comma or semicolon). Must be in parentheses; This is required to enable providing a comma as separator.
- fixed\_arg – Fixed argument passed to F as the third macro parameter.
- ... – Variable list of arguments. The macro F is invoked as F(index, element, fixed\_arg) for each element in the list.

REVERSE\_ARGS(...)

Reverse arguments order.

#### Parameters

- ... – Variable argument list.

NUM\_VA\_ARGS\_LESS\_1(...)

Number of arguments in the variable arguments list minus one.

**Parameters**

- ... – List of arguments

**Returns** Number of variadic arguments in the argument list, minus one

MACRO\_MAP\_CAT(...)

Mapping macro that pastes results together.

This is similar to [FOR\\_EACH\(\)](#) in that it invokes a macro repeatedly on each element of . However, unlike [FOR\\_EACH\(\)](#), [MACRO\\_MAP\\_CAT\(\)](#) pastes the results together into a single token.

For example, with this macro FOO:

```
#define FOO(x) item_##x##_
```

[MACRO\\_MAP\\_CAT\(FOO, a, b, c\)](#) , expands to the token:

```
item_a_item_b_item_c_
```

**Parameters**

- ... – Macro to expand on each argument, followed by its arguments. (The macro should take exactly one argument.)

**Returns** The results of expanding the macro on each argument, all pasted together

MACRO\_MAP\_CAT\_N(N, ...)

Mapping macro that pastes a fixed number of results together.

Similar to [MACRO\\_MAP\\_CAT\(\)](#), but expects a fixed number of arguments. If more arguments are given than are expected, the rest are ignored.

**Parameters**

- N – Number of arguments to map
- ... – Macro to expand on each argument, followed by its arguments. (The macro should take exactly one argument.)

**Returns** The results of expanding the macro on each argument, all pasted together

## Functions

static inline bool is\_power\_of\_two(unsigned int x)

Is x a power of two?

**Parameters**

- x – value to check

**Returns** true if x is a power of two, false otherwise

static inline int64\_t arithmetic\_shift\_right(int64\_t value, uint8\_t shift)

Arithmetic shift right.

**Parameters**

- value – value to shift
- shift – number of bits to shift

**Returns** value shifted right by `shift`; opened bit positions are filled with the sign bit

static inline void bytecpy(void \*dst, const void \*src, size\_t size)  
byte by byte memcpy.

Copy `size` bytes of `src` into `dest`. This is guaranteed to be done byte by byte.

**Parameters**

- `dst` – Pointer to the destination memory.
- `src` – Pointer to the source of the data.
- `size` – The number of bytes to copy.

int char2hex(char c, uint8\_t \*x)

Convert a single character into a hexadecimal nibble.

**Parameters**

- `c` – The character to convert
- `x` – The address of storage for the converted number.

**Returns** Zero on success or (negative) error code otherwise.

int hex2char(uint8\_t x, char \*c)

Convert a single hexadecimal nibble into a character.

**Parameters**

- `c` – The number to convert
- `x` – The address of storage for the converted character.

**Returns** Zero on success or (negative) error code otherwise.

size\_t bin2hex(const uint8\_t \*buf, size\_t buflen, char \*hex, size\_t hexlen)

Convert a binary array into string representation.

**Parameters**

- `buf` – The binary array to convert
- `buflen` – The length of the binary array to convert
- `hex` – Address of where to store the string representation.
- `hexlen` – Size of the storage area for string representation.

**Returns** The length of the converted string, or 0 if an error occurred.

size\_t hex2bin(const char \*hex, size\_t hexlen, uint8\_t \*buf, size\_t buflen)

Convert a hexadecimal string into a binary array.

**Parameters**

- `hex` – The hexadecimal string to convert
- `hexlen` – The length of the hexadecimal string to convert.
- `buf` – Address of where to store the binary data
- `buflen` – Size of the storage area for binary data

**Returns** The length of the binary array, or 0 if an error occurred.

static inline uint8\_t bcd2bin(uint8\_t bcd)

Convert a binary coded decimal (BCD 8421) value to binary.

**Parameters**

- `bcd` – BCD 8421 value to convert.

**Returns** Binary representation of input value.

`static inline uint8_t bin2bcd(uint8_t bin)`

Convert a binary value to binary coded decimal (BCD 8421).

**Parameters**

- `bin` – Binary value to convert.

**Returns** BCD 8421 representation of input value.

`uint8_t u8_to_dec(char *buf, uint8_t buflen, uint8_t value)`

Convert a `uint8_t` into a decimal string representation.

Convert a `uint8_t` value into its ASCII decimal string representation. The string is terminated if there is enough space in `buf`.

**Parameters**

- `buf` – Address of where to store the string representation.
- `buflen` – Size of the storage area for string representation.
- `value` – The value to convert to decimal string

**Returns** The length of the converted string (excluding terminator if any), or 0 if an error occurred.

## 7.32 Settings

The settings subsystem gives modules a way to store persistent per-device configuration and runtime state. A variety of storage implementations are provided behind a common API using FCB, NVS, or a file system. These different implementations give the application developer flexibility to select an appropriate storage medium, and even change it later as needs change. This subsystem is used by various Zephyr components and can be used simultaneously by user applications.

Settings items are stored as key-value pair strings. By convention, the keys can be organized by the package and subtree defining the key, for example the key `id/serial` would define the `serial` configuration element for the package `id`.

Convenience routines are provided for converting a key value to and from a string type.

For an example of the settings subsystem refer to the sample.

---

**Note:** As of Zephyr release 2.1 the recommended backend for non-filesystem storage is [NVS](#).

---

### 7.32.1 Handlers

Settings handlers for subtree implement a set of handler functions. These are registered using a call to `settings_register()`.

**h\_get** This gets called when asking for a settings element value by its name using `settings_runtime_get()` from the runtime backend.

**h\_set** This gets called when the value is loaded from persisted storage with `settings_load()`, or when using `settings_runtime_set()` from the runtime backend.

**h\_commit** This gets called after the settings have been loaded in full. Sometimes you don't want an individual setting value to take effect right away, for example if there are multiple settings which are interdependent.

**h\_export** This gets called to write all current settings. This happens when `settings_save()` tries to save the settings or transfer to any user-implemented back-end.

### 7.32.2 Backends

Backends are meant to load and save data to/from setting handlers, and implement a set of handler functions. These are registered using a call to `settings_src_register()` for backends that can load data, and/or `settings_dst_register()` for backends that can save data. The current implementation allows for multiple source backends but only a single destination backend.

**csi\_load** This gets called when loading values from persistent storage using `settings_load()`.

**csi\_save** This gets called when saving a single setting to persistent storage using `settings_save_one()`.

**csi\_save\_start** This gets called when starting a save of all current settings using `settings_save()`.

**csi\_save\_end** This gets called after having saved of all current settings using `settings_save()`.

### 7.32.3 Zephyr Storage Backends

Zephyr has three storage backends: a Flash Circular Buffer (`:kconfig:CONFIG_SETTINGS_FCB`), a file in the filesystem (`:kconfig:CONFIG_SETTINGS_FS`), or non-volatile storage (`:kconfig:CONFIG_SETTINGS_NVS`).

You can declare multiple sources for settings; settings from all of these are restored when `settings_load()` is called.

There can be only one target for writing settings; this is where data is stored when you call `settings_save()`, or `settings_save_one()`.

FCB read target is registered using `settings_fcb_src()`, and write target using `settings_fcb_dst()`. As a side-effect, `settings_fcb_src()` initializes the FCB area, so it must be called before calling `settings_fcb_dst()`. File read target is registered using `settings_file_src()`, and write target by using `settings_file_dst()`. Non-volatile storage read target is registered using `settings_nvs_src()`, and write target by using `settings_nvs_dst()`.

### 7.32.4 Loading data from persisted storage

A call to `settings_load()` uses an `h_set` implementation to load settings data from storage to volatile memory. After all data is loaded, the `h_commit` handler is issued, signalling the application that the settings were successfully retrieved.

Technically FCB and filesystem backends may store some history of the entities. This means that the newest data entity is stored after any older existing data entities. Starting with Zephyr 2.1, the back-end must filter out all old entities and call the callback with only the newest entity.

### 7.32.5 Storing data to persistent storage

A call to `settings_save_one()` uses a backend implementation to store settings data to the storage medium. A call to `settings_save()` uses an `h_export` implementation to store different data in one operation using `settings_save_one()`. A key need to be covered by a `h_export` only if it is supposed to be stored by `settings_save()` call.

For both FCB and filesystem back-end only storage requests with data which changes most actual key's value are stored, therefore there is no need to check whether a value changed by the application. Such a storage mechanism implies that storage can contain multiple value assignments for a key, while only the last is the current value for the key.

## Garbage collection

When storage becomes full (FCB) or consumes too much space (file system), the backend removes non-recent key-value pairs records and unnecessary key-delete records.

### 7.32.6 Example: Device Configuration

This is a simple example, where the settings handler only implements `h_set` and `h_export`. `h_set` is called when the value is restored from storage (or when set initially), and `h_export` is used to write the value to storage thanks to `storage_func()`. The user can also implement some other export functionality, for example, writing to the shell console).

```
#define DEFAULT_FOO_VAL_VALUE 1

static int8 foo_val = DEFAULT_FOO_VAL_VALUE;

static int foo_settings_set(const char *name, size_t len,
                           settings_read_cb read_cb, void *cb_arg)
{
    const char *next;
    int rc;

    if (settings_name_steq(name, "bar", &next) && !next) {
        if (len != sizeof(foo_val)) {
            return -EINVAL;
        }

        rc = read_cb(cb_arg, &foo_val, sizeof(foo_val));
        if (rc >= 0) {
            /* key-value pair was properly read.
             * rc contains value length.
             */
            return 0;
        }
        /* read-out error */
        return rc;
    }

    return -ENOENT;
}

static int foo_settings_export(int (*storage_func)(const char *name,
                                                    void *value,
                                                    size_t val_len))
{
    return storage_func("foo/bar", &foo_val, sizeof(foo_val));
}

struct settings_handler my_conf = {
    .name = "foo",
    .h_set = foo_settings_set,
    .h_export = foo_settings_export
};
```

### 7.32.7 Example: Persist Runtime State

This is a simple example showing how to persist runtime state. In this example, only `h_set` is defined, which is used when restoring value from persisted storage.

In this example, the main function increments `foo_val`, and then persists the latest number. When the system restarts, the application calls `settings_load()` while initializing, and `foo_val` will continue counting up from where it was before restart.

```
#include <zephyr.h>
#include <sys/reboot.h>
#include <settings/settings.h>
#include <sys/printk.h>
#include <inttypes.h>

#define DEFAULT_FOO_VAL_VALUE 0

static uint8_t foo_val = DEFAULT_FOO_VAL_VALUE;

static int foo_settings_set(const char *name, size_t len,
                           settings_read_cb read_cb, void *cb_arg)
{
    const char *next;
    int rc;

    if (settings_name_steq(name, "bar", &next) && !next) {
        if (len != sizeof(foo_val)) {
            return -EINVAL;
        }

        rc = read_cb(cb_arg, &foo_val, sizeof(foo_val));
        if (rc >= 0) {
            return 0;
        }

        return rc;
    }

    return -ENOENT;
}

struct settings_handler my_conf = {
    .name = "foo",
    .h_set = foo_settings_set
};

void main(void)
{
    settings_subsys_init();
    settings_register(&my_conf);
    settings_load();

    foo_val++;
    settings_save_one("foo/bar", &foo_val, sizeof(foo_val));

    printk("foo: %d\n", foo_val);
}
```

(continues on next page)

(continued from previous page)

```
k_sleep(1000);
sys_reboot(SYS_REBOOT_COLD);
}
```

### 7.32.8 Example: Custom Backend Implementation

This is a simple example showing how to register a simple custom backend handler (**:kconfig: `CONFIG_SETTINGS_CUSTOM`**).

```
static int settings_custom_load(struct settings_store *cs)
{
    //...
}

static int settings_custom_save(struct settings_store *cs, const char *name,
                               const char *value, size_t val_len)
{
    //...
}

/* custom backend interface */
static struct settings_store_itf settings_custom_itf = {
    .csi_load = settings_custom_load,
    .csi_save = settings_custom_save,
};

/* custom backend node */
static struct settings_store settings_custom_store = {
    .cs_itf = &settings_custom_itf
}

int settings_backend_init(void)
{
    /* register custom backend */
    settings_dst_register(&settings_custom_store);
    settings_src_register(&settings_custom_store);
    return 0;
}
```

### 7.32.9 API Reference

The Settings subsystem APIs are provided by `settings.h`:

#### API for general settings usage

*group settings*

#### Defines

`SETTINGS_MAX_DIR_DEPTH`

SETTINGS\_MAX\_NAME\_LEN

SETTINGS\_MAX\_VAL\_LEN

SETTINGS\_NAME\_SEPARATOR

SETTINGS\_NAME\_END

SETTINGS\_EXTRA\_LEN

SETTINGS\_STATIC\_HANDLER\_DEFINE(\_hname, \_tree, \_get, \_set, \_commit, \_export)

Define a static handler for settings items

This creates a variable *hname* prepended by [settings\\_handler](#).

#### Parameters

- `_hname` – handler name
- `_tree` – subtree name
- `_get` – get routine (can be NULL)
- `_set` – set routine (can be NULL)
- `_commit` – commit routine (can be NULL)
- `_export` – export routine (can be NULL)

#### Typedefs

```
typedef ssize_t (*settings_read_cb)(void *cb_arg, void *data, size_t len)
```

Function used to read the data from the settings storage in `h_set` handler implementations.

**Param `cb_arg` [in]** arguments for the read function. Appropriate `cb_arg` is transferred to `h_set` handler implementation by the backend.

**Param `data` [out]** the destination buffer

**Param `len` [in]** length of read

**Return** positive: Number of bytes read, 0: key-value pair is deleted. On error returns `-ERRNO` code.

```
typedef int (*settings_load_direct_cb)(const char *key, size_t len, settings_read_cb read_cb, void *cb_arg, void *param)
```

Callback function used for direct loading. Used by [settings\\_load\\_subtree\\_direct](#) function.

- `key[in]` the name with skipped part that was used as name in handler registration
- `len[in]` the size of the data found in the backend.
- `read_cb[in]` function provided to read the data from the backend.
- `cb_arg[in]` arguments for the read function provided by the backend.

**Param `key` [in]** the name with skipped part that was used as name in handler registration

**Param len [in]** the size of the data found in the backend.

**Param read\_cb [in]** function provided to read the data from the backend.

**Param cb\_arg [inout]** arguments for the read function provided by the backend.

**Param param [inout]** parameter given to the [settings\\_load\\_subtree\\_direct](#) function.

**Return** When nonzero value is returned, further subtree searching is stopped. Use with care as some settings backends would iterate through old values, and the current value is returned last.

## Functions

`int settings_subsys_init(void)`

Initialization of settings and backend

Can be called at application startup. In case the backend is a FS Remember to call it after the FS was mounted. For FCB backend it can be called without such a restriction.

**Returns** 0 on success, non-zero on failure.

`int settings_register(struct settings\_handler *cf)`

Register a handler for settings items stored in RAM.

### Parameters

- `cf` – Structure containing registration info.

**Returns** 0 on success, non-zero on failure.

`int settings_load(void)`

Load serialized items from registered persistence sources. Handlers for serialized item subtrees registered earlier will be called for encountered values.

**Returns** 0 on success, non-zero on failure.

`int settings_load_subtree(const char *subtree)`

Load limited set of serialized items from registered persistence sources. Handlers for serialized item subtrees registered earlier will be called for encountered values that belong to the subtree.

### Parameters

- `subtree` – **[in]** name of the subtree to be loaded.

**Returns** 0 on success, non-zero on failure.

`int settings_load_subtree_direct(const char *subtree, settings\_load\_direct\_cb cb, void *param)`

Load limited set of serialized items using given callback.

This function bypasses the normal data workflow in settings module. All the settings values that are found are passed to the given callback.

---

**Note:** This function does not call commit function. It works as a blocking function, so it is up to the user to call any kind of commit function when this operation ends.

---

### Parameters

- `subtree` – **[in]** subtree name of the subtree to be loaded.
- `cb` – **[in]** pointer to the callback function.
- `param` – **[inout]** parameter to be passed when callback function is called.

**Returns** 0 on success, non-zero on failure.

`int settings_save(void)`

Save currently running serialized items. All serialized items which are different from currently persisted values will be saved.

**Returns** 0 on success, non-zero on failure.

`int settings_save_one(const char *name, const void *value, size_t val_len)`

Write a single serialized value to persisted storage (if it has changed value).

**Parameters**

- `name` – Name/key of the settings item.
- `value` – Pointer to the value of the settings item. This value will be transferred to the [settings\\_handler::h\\_export](#) handler implementation.
- `val_len` – Length of the value.

**Returns** 0 on success, non-zero on failure.

`int settings_delete(const char *name)`

Delete a single serialized in persisted storage.

Deleting an existing key-value pair in the settings mean to set its value to NULL.

**Parameters**

- `name` – Name/key of the settings item.

**Returns** 0 on success, non-zero on failure.

`int settings_commit(void)`

Call commit for all settings handler. This should apply all settings which has been set, but not applied yet.

**Returns** 0 on success, non-zero on failure.

`int settings_commit_subtree(const char *subtree)`

Call commit for settings handler that belong to subtree. This should apply all settings which has been set, but not applied yet.

**Parameters**

- `subtree` – **[in]** name of the subtree to be committed.

**Returns** 0 on success, non-zero on failure.

`struct settings_handler`

*#include <settings.h>* Config handlers for subtree implement a set of handler functions. These are registered using a call to [settings\\_register](#).

**Public Members**

`const char *name`

Name of subtree.

`int (*h_get)(const char *key, char *val, int val_len_max)`

Get values handler of settings items identified by keyword names.

Parameters:

- `key[in]` the name with skipped part that was used as name in handler registration

- val[out] buffer to receive value.
- val\_len\_max[in] size of that buffer.

Return: length of data read on success, negative on failure.

int (\*h\_set)(const char \*key, size\_t len, [settings\\_read\\_cb](#) read\_cb, void \*cb\_arg)

Set value handler of settings items identified by keyword names.

Parameters:

- key[in] the name with skipped part that was used as name in handler registration
- len[in] the size of the data found in the backend.
- read\_cb[in] function provided to read the data from the backend.
- cb\_arg[in] arguments for the read function provided by the backend.

Return: 0 on success, non-zero on failure.

int (\*h\_commit)(void)

This handler gets called after settings has been loaded in full. User might use it to apply setting to the application.

Return: 0 on success, non-zero on failure.

int (\*h\_export)(int (\*export\_func)(const char \*name, const void \*val, size\_t val\_len))

This gets called to dump all current settings items.

This happens when [settings\\_save](#) tries to save the settings. Parameters:

- export\_func: the pointer to the internal function which appends a single key-value pair to persisted settings. Don't store duplicated value. The name is subtree/key string, val is the string with value.

Return: 0 on success, non-zero on failure.

---

### Remark

The User might limit a implementations of handler to serving only one keyword at one call - what will impose limit to get/set values using full subtree/key name.

---

sys\_snode\_t node

Linked list node info for module internal usage.

struct settings\_handler\_static

*#include <settings.h>* Config handlers without the node element, used for static handlers. These are registered using a call to `SETTINGS_REGISTER_STATIC()`.

### Public Members

const char \*name

Name of subtree.

int (\*h\_get)(const char \*key, char \*val, int val\_len\_max)

Get values handler of settings items identified by keyword names.

Parameters:

- key[in] the name with skipped part that was used as name in handler registration
- val[out] buffer to receive value.
- val\_len\_max[in] size of that buffer.

Return: length of data read on success, negative on failure.

```
int (*h_set)(const char *key, size_t len, settings\_read\_cb read_cb, void *cb_arg)
```

Set value handler of settings items identified by keyword names.

Parameters:

- `key[in]` the name with skipped part that was used as name in handler registration
- `len[in]` the size of the data found in the backend.
- `read_cb[in]` function provided to read the data from the backend.
- `cb_arg[in]` arguments for the read function provided by the backend.

Return: 0 on success, non-zero on failure.

```
int (*h_commit)(void)
```

This handler gets called after settings has been loaded in full. User might use it to apply setting to the application.

```
int (*h_export)(int (*export_func)(const char *name, const void *val, size_t val_len))
```

This gets called to dump all current settings items.

This happens when [settings\\_save](#) tries to save the settings. Parameters:

- `export_func`: the pointer to the internal function which appends a single key-value pair to persisted settings. Don't store duplicated value. The name is subtree/key string, val is the string with value.

Return: 0 on success, non-zero on failure.

---

#### Remark

The User might limit a implementations of handler to serving only one keyword at one call - what will impose limit to get/set values using full subtree/key name.

---

## API for key-name processing

*group* `settings_name_proc`

API for const name processing.

### Functions

```
int settings_name_steq(const char *name, const char *key, const char **next)
```

Compares the start of name with a key

Some examples: `settings_name_steq("bt/btmesh/iv", "b", &next)` returns 1, `next="t/btmesh/iv"` `settings_name_steq("bt/btmesh/iv", "bt", &next)` returns 1, `next="btmesh/iv"` `settings_name_steq("bt/btmesh/iv", "bt/", &next)` returns 0, `next=NULL` `settings_name_steq("bt/btmesh/iv", "bta", &next)` returns 0, `next=NULL`

REMARK: This routine could be simplified if the [settings\\_handler](#) names would include a separator at the end.

#### Parameters

- `name` – **[in]** in string format
- `key` – **[in]** comparison string

- `next` – **[out]** pointer to remaining of name, when the remaining part starts with a separator the separator is removed from `next`

**Returns** 0: no match 1: match, `next` can be used to check if match is full

`int settings_name_next(const char *name, const char **next)`

determine the number of characters before the first separator

#### Parameters

- `name` – **[in]** in string format
- `next` – **[out]** pointer to remaining of name (excluding separator)

**Returns** index of the first separator, in case no separator was found this is the size of `name`

## API for runtime settings manipulation

*group* `settings_rt`

API for runtime settings.

### Functions

`int settings_runtime_set(const char *name, const void *data, size_t len)`

Set a value with a specific key to a module handler.

#### Parameters

- `name` – Key in string format.
- `data` – Binary value.
- `len` – Value length in bytes.

**Returns** 0 on success, non-zero on failure.

`int settings_runtime_get(const char *name, void *data, size_t len)`

Get a value corresponding to a key from a module handler.

#### Parameters

- `name` – Key in string format.
- `data` – Returned binary value.
- `len` – requested value length in bytes.

**Returns** length of data read on success, negative on failure.

`int settings_runtime_commit(const char *name)`

Apply settings in a module handler.

#### Parameters

- `name` – Key in string format.

**Returns** 0 on success, non-zero on failure.

## API of backend interface

*group* `settings_backend`

`settings`

## Functions

void settings\_src\_register(struct [settings\\_store](#) \*cs)

Register a backend handler acting as source.

### Parameters

- cs – Backend handler node containing handler information.

void settings\_dst\_register(struct [settings\\_store](#) \*cs)

Register a backend handler acting as destination.

### Parameters

- cs – Backend handler node containing handler information.

struct settings\_handler\_ \*settings\_parse\_and\_lookup(const char \*name, const char \*\*next)

Parses a key to an array of elements and locate corresponding module handler.

### Parameters

- name – **[in]** in string format
- next – **[out]** remaining of name after matched handler

**Returns** [settings\\_handler\\_static](#) on success, NULL on failure.

int settings\_call\_set\_handler(const char \*name, size\_t len, [settings\\_read\\_cb](#) read\_cb, void \*read\_cb\_arg, const struct [settings\\_load\\_arg](#) \*load\_arg)

Calls settings handler.

### Parameters

- name – **[in]** The name of the data found in the backend.
- len – **[in]** The size of the data found in the backend.
- read\_cb – **[in]** Function provided to read the data from the backend.
- read\_cb\_arg – **[inout]** Arguments for the read function provided by the backend.
- load\_arg – **[inout]** Arguments for data loading.

**Returns** 0 or negative error code

struct settings\_store

*#include <settings.h>* Backend handler node for storage handling.

## Public Members

sys\_snode\_t cs\_next

Linked list node info for internal usage.

const struct [settings\\_store\\_itf](#) \*cs\_itf

Backend handler structure.

struct settings\_load\_arg

*#include <settings.h>* Arguments for data loading. Holds all parameters that changes the way data should be loaded from backend.

## Public Members

const char \*subtree

Name of the subtree to be loaded.

If NULL, all values would be loaded.

[settings\\_load\\_direct\\_cb](#) cb

Pointer to the callback function.

If NULL then matching registered function would be used.

void \*param

Parameter for callback function.

Parameter to be passed to the callback function.

struct settings\_store\_itf

*#include <settings.h>* Backend handler functions. Sources are registered using a call to [settings\\_src\\_register](#). Destinations are registered using a call to [settings\\_dst\\_register](#).

## Public Members

int (\*csi\_load)(struct [settings\\_store](#) \*cs, const struct [settings\\_load\\_arg](#) \*arg)

Loads values from storage limited to subtree defined by subtree.

Parameters:

- cs - Corresponding backend handler node,
- arg - Structure that holds additional data for data loading.

---

**Note:** Backend is expected not to provide duplicates of the entities. It means that if the backend does not contain any functionality to really delete old keys, it has to filter out old entities and call load callback only on the final entity.

---

int (\*csi\_save\_start)(struct [settings\\_store](#) \*cs)

Handler called before an export operation.

Parameters:

- cs - Corresponding backend handler node

int (\*csi\_save)(struct [settings\\_store](#) \*cs, const char \*name, const char \*value, size\_t val\_len)

Save a single key-value pair to storage.

Parameters:

- cs - Corresponding backend handler node
- name - Key in string format
- value - Binary value
- val\_len - Length of value in bytes.

int (\*csi\_save\_end)(struct [settings\\_store](#) \*cs)

Handler called after an export operation.

Parameters:

- cs - Corresponding backend handler node

## 7.33 Executing Time Functions

The timing functions can be used to obtain execution time of a section of code to aid in analysis and optimization.

Please note that the timing functions may use a different timer than the default kernel timer, where the timer being used is specified by architecture, SoC or board configuration.

### 7.33.1 Configuration

To allow using the timing functions, `:kconfig: `CONFIG_TIMING_FUNCTIONS`` needs to be enabled.

### 7.33.2 Usage

To gather timing information:

1. Call `timing_init()` to initialize the timer.
2. Call `timing_start()` to signal the start of gathering of timing information. This usually starts the timer.
3. Call `timing_counter_get()` to mark the start of code execution.
4. Call `timing_counter_get()` to mark the end of code execution.
5. Call `timing_cycles_get()` to get the number of timer cycles between start and end of code execution.
6. Call `timing_cycles_to_ns()` with total number of cycles to convert number of cycles to nanoseconds.
7. Repeat from step 3 to gather timing information for other blocks of code.
8. Call `timing_stop()` to signal the end of gathering of timing information. This usually stops the timer.

### Example

This shows an example on how to use the timing functions:

```
#include <timing/timing.h>

void gather_timing(void)
{
    timing_t start_time, end_time;
    uint64_t total_cycles;
    uint64_t total_ns;

    timing_init();
    timing_start();

    start_time = timing_counter_get();

    code_execution_to_be_measured();

    end_time = timing_counter_get();

    total_cycles = timing_cycles_get(&start_time, &end_time);
    total_ns = timing_cycles_to_ns(total_cycles);
}
```

(continues on next page)

(continued from previous page)

```
    timing_stop();  
}
```

### 7.33.3 API documentation

*group* timing\_api

Timing Measurement APIs.

#### Functions

`void timing_init(void)`

Initialize the timing subsystem.

Perform the necessary steps to initialize the timing subsystem.

`void timing_start(void)`

Signal the start of the timing information gathering.

Signal to the timing subsystem that timing information will be gathered from this point forward.

`void timing_stop(void)`

Signal the end of the timing information gathering.

Signal to the timing subsystem that timing information is no longer being gathered from this point forward.

`static inline timing_t timing_counter_get(void)`

Return timing counter.

**Returns** Timing counter.

`static inline uint64_t timing_cycles_get(volatile timing_t *const start, volatile timing_t *const end)`

Get number of cycles between `start` and `end`.

For some architectures or SoCs, the raw numbers from counter need to be scaled to obtain actual number of cycles.

#### Parameters

- `start` – Pointer to counter at start of a measured execution.
- `end` – Pointer to counter at stop of a measured execution.

**Returns** Number of cycles between `start` and `end`.

`static inline uint64_t timing_freq_get(void)`

Get frequency of counter used (in Hz).

**Returns** Frequency of counter used for timing in Hz.

`static inline uint64_t timing_cycles_to_ns(uint64_t cycles)`

Convert number of cycles into nanoseconds.

#### Parameters

- `cycles` – Number of cycles

**Returns** Converted time value

```
static inline uint64_t timing_cycles_to_ns_avg(uint64_t cycles, uint32_t count)
```

Convert number of cycles into nanoseconds with averaging.

#### Parameters

- `cycles` – Number of cycles
- `count` – Times of accumulated cycles to average over

**Returns** Converted time value

```
static inline uint32_t timing_freq_get_mhz(void)
```

Get frequency of counter used (in MHz).

**Returns** Frequency of counter used for timing in MHz.

## 7.34 Virtualization

### 7.34.1 Inter-VM Shared Memory

- [Overview](#)
- [Support](#)
- [API Reference](#)

#### Overview

As Zephyr is enabled to run as a guest OS on Qemu and [ACRN](#) it might be necessary to make VMs aware of each other, or aware of the host. This is made possible by exposing a shared memory among parties via a feature called `ivshmem`, which stands for inter-VM Shared Memory.

The Two types are supported: a plain shared memory (`ivshmem-plain`) or a shared memory with the ability for a VM to generate an interruption on another, and thus to be interrupted as well itself (`ivshmem-doorbell`).

Please refer to the official [Qemu ivshmem documentation](#) for more information.

#### Support

Zephyr supports both version: `plain` and `doorbell`. `Ivshmem` driver can be build by enabling `:kconfig: 'CONFIG_IVSHMEM'`. By default, this will expose the plain version. `:kconfig: 'CONFIG_IVSHMEM_DOORBELL'` needs to be enabled to get the doorbell version.

Because the doorbell version uses MSI-X vectors to support notification vectors, the `:kconfig: 'CONFIG_IVSHMEM_MSI_X_VECTORS'` has to be tweaked to the amount of vectors that will be needed.

Note that a tiny shell module can be exposed to test the `ivshmem` feature by enabling `:kconfig: 'CONFIG_IVSHMEM_SHELL'`.

#### API Reference

`group ivshmem`

`ivshmem` reference API

## Typedefs

```
typedef size_t (*ivshmem_get_mem_f)(const struct device *dev, uintptr_t *memmap)
```

```
typedef uint32_t (*ivshmem_get_id_f)(const struct device *dev)
```

```
typedef uint16_t (*ivshmem_get_vectors_f)(const struct device *dev)
```

```
typedef int (*ivshmem_int_peer_f)(const struct device *dev, uint32_t peer_id, uint16_t vector)
```

```
typedef int (*ivshmem_register_handler_f)(const struct device *dev, struct k_poll_signal *signal, uint16_t vector)
```

## Functions

```
size_t ivshmem_get_mem(const struct device *dev, uintptr_t *memmap)
```

Get the inter-VM shared memory.

### Parameters

- *dev* – Pointer to the device structure for the driver instance
- *memmap* – A pointer to fill in with the memory address

**Returns** the size of the memory mapped, or 0

```
uint32_t ivshmem_get_id(const struct device *dev)
```

Get our VM ID.

### Parameters

- *dev* – Pointer to the device structure for the driver instance

**Returns** our VM ID or 0 if we are not running on doorbell version

```
uint16_t ivshmem_get_vectors(const struct device *dev)
```

Get the number of interrupt vectors we can use.

### Parameters

- *dev* – Pointer to the device structure for the driver instance

**Returns** the number of available interrupt vectors

```
int ivshmem_int_peer(const struct device *dev, uint32_t peer_id, uint16_t vector)
```

Interrupt another VM.

### Parameters

- *dev* – Pointer to the device structure for the driver instance
- *peer\_id* – The VM ID to interrupt
- *vector* – The interrupt vector to use

**Returns** 0 on success, a negative *errno* otherwise

```
int ivshmem_register_handler(const struct device *dev, struct k_poll_signal *signal, uint16_t vector)
```

Register a vector notification (interrupt) handler.

Note: The returned status, if positive, to a raised signal is the vector that generated the signal. This lets the possibility to the user to have one signal for all vectors, or one per-vector.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance
- `signal` – A pointer to a valid and ready to be signaled struct [k\\_poll\\_signal](#). Or NULL to unregister any handler registered for the given vector.
- `vector` – The interrupt vector to get notification from

**Returns** 0 on success, a negative errno otherwise

```
struct ivshmem_driver_api
#include <ivshmem.h>
```

# Chapter 8

## User and Developer Guides

### 8.1 Beyond the Getting Started Guide

The [Getting Started Guide](#) gives a straight-forward path to set up your Linux, macOS, or Windows environment for Zephyr development. In this document, we delve deeper into Zephyr development setup issues and alternatives.

#### 8.1.1 Python and pip

Python 3 and its package manager, `pip`<sup>1</sup>, are used extensively by Zephyr to install and run scripts required to compile and run Zephyr applications, set up and maintain the Zephyr development environment, and build project documentation.

Depending on your operating system, you may need to provide the `--user` flag to the `pip3` command when installing new packages. This is documented throughout the instructions. See [Installing Packages](#) in the Python Packaging User Guide for more information about `pip`<sup>1</sup>, including [information on `--user`](#).

- On Linux, make sure `~/local/bin` is at the front of your `PATH` [environment variable](#), or programs installed with `--user` won't be found. Installing with `--user` avoids conflicts between `pip` and the system package manager, and is the default on Debian-based distributions.
- On macOS, [Homebrew disables `--user`](#).
- On Windows, see the [Installing Packages](#) information on `--user` if you require using this option.

On all operating systems, `pip`'s `-U` flag installs or updates the package if the package is already installed locally but a more recent version is available. It is good practice to use this flag if the latest version of a package is required. (Check the [scripts/requirements.txt](#) file to see if a specific Python package version is expected.)

#### 8.1.2 Advanced Setup and tool chain alternatives

Here are some alternative instructions for more advanced platform setup configurations for supported development platforms:

---

<sup>1</sup> `pip` is Python's package installer. Its `install` command first tries to re-use packages and package dependencies already installed on your computer. If that is not possible, `pip install` downloads them from the Python Package Index (PyPI) on the Internet.

The package versions requested by Zephyr's `requirements.txt` may conflict with other requirements on your system, in which case you may want to set up a `virtualenv` for Zephyr development.

### Install Linux Host Dependencies

Documentation is available for these Linux distributions:

- Ubuntu
- Fedora
- Clear Linux
- Arch Linux

For distributions that are not based on rolling releases, some of the requirements and dependencies may not be met by your package manager. In that case please follow the additional instructions that are provided to find software from sources other than the package manager.

---

**Note:** If you're working behind a corporate firewall, you'll likely need to configure a proxy for accessing the internet, if you haven't done so already. While some tools use the environment variables `http_proxy` and `https_proxy` to get their proxy settings, some use their own configuration files, most notably `apt` and `git`.

---

**Update Your Operating System** Ensure your host system is up to date.

Ubuntu

```
sudo apt-get update
sudo apt-get upgrade
```

Fedora

```
sudo dnf upgrade
```

Clear Linux

```
sudo swupd update
```

Arch Linux

```
sudo pacman -Syu
```

**Install Requirements and Dependencies** Note that both Ninja and Make are installed with these instructions; you only need one.

Ubuntu

```
sudo apt-get install --no-install-recommends git cmake ninja-build gperf \
  ccache dfu-util device-tree-compiler wget \
  python3-dev python3-pip python3-setuptools python3-tk python3-wheel xz-utils file_
↳ libpython3.8-dev \
  make gcc gcc-multilib g++-multilib libsdl2-dev
```

Fedora

```
sudo dnf group install "Development Tools" "C Development Tools and Libraries"
dnf install git cmake ninja-build gperf ccache dfu-util dtc wget \
  python3-pip python3-tkinter xz file glibc-devel.i686 libstdc++-devel.i686 python38 \
  SDL2-devel
```

Clear Linux

```
sudo swupd bundle-add c-basic dev-utils dfu-util dtc \
  os-core-dev python-basic python3-basic python3-tcl
```

The Clear Linux focus is on *native* performance and security and not cross-compilation. For that reason it uniquely exports by default to the [environment](#) of all users a list of compiler and linker flags. Zephyr's CMake build system will either warn or fail because of these. To clear the C/C++ flags among these and fix the Zephyr build, run the following command as root then log out and back in:

```
echo 'unset CFLAGS CXXFLAGS' >> /etc/profile.d/unset_cflags.sh
```

Note this command unsets the C/C++ flags for *all users on the system*. Each Linux distribution has a unique, relatively complex and potentially evolving sequence of bash initialization files sourcing each other and Clear Linux is no exception. If you need a more flexible solution, start by looking at the logic in `/usr/share/defaults/etc/profile`.

#### Arch Linux

```
sudo pacman -S git cmake ninja gperf ccache dfu-util dtc wget \
  python-pip python-setuptools python-wheel tk xz file make
```

**CMake** A [recent CMake version](#) is required. Check what version you have by using `cmake --version`. If you have an older version, there are several ways of obtaining a more recent one:

- On Ubuntu, you can follow the instructions for adding the [kitware third-party apt repository](#) to get an updated version of cmake using apt.
- Download and install a packaged cmake from the CMake project site. (Note this won't uninstall the previous version of cmake.)

```
cd ~
wget https://github.com/Kitware/CMake/releases/download/v3.21.1/cmake-3.21.1-
  ↳Linux-x86_64.sh
chmod +x cmake-3.21.1-Linux-x86_64.sh
sudo ./cmake-3.21.1-Linux-x86_64.sh --skip-license --prefix=/usr/local
hash -r
```

The `hash -r` command may be necessary if the installation script put cmake into a new location on your PATH.

- Download and install from the pre-built binaries provided by the CMake project itself in the [CMake Downloads](#) page. For example, to install version 3.21.1 in `~/bin/cmake`:

```
mkdir $HOME/bin/cmake && cd $HOME/bin/cmake
wget https://github.com/Kitware/CMake/releases/download/v3.21.1/cmake-3.21.1-
  ↳Linux-x86_64.sh
yes | sh cmake-3.21.1-Linux-x86_64.sh | cat
echo "export PATH=$PWD/cmake-3.21.1-Linux-x86_64/bin:$PATH" >> $HOME/.zephyrrc
```

- Use pip3:

```
pip3 install --user cmake
```

Note this won't uninstall the previous version of cmake and will install the new cmake into your `~/.local/bin` folder so you'll need to add `~/.local/bin` to your PATH. (See [Python and pip](#) for details.)

- Check your distribution's beta or unstable release package library for an update.
- On Ubuntu you can also use snap to get the latest version available:

```
sudo snap install cmake
```

After updating cmake, verify that the newly installed cmake is found using `cmake --version`. You might also want to uninstall the CMake provided by your package manager to avoid conflicts. (Use `whereis cmake` to find other installed versions.)

**DTC (Device Tree Compiler)** A [recent DTC version](#) is required. Check what version you have by using `dtc --version`. If you have an older version, either install a more recent one by building from source, or use the one that is bundled in the [Zephyr SDK](#) by installing it.

**Python** A [modern Python 3 version](#) is required. Check what version you have by using `python3 --version`.

If you have an older version, you will need to install a more recent Python 3. You can build from source, or use a backport from your distribution's package manager channels if one is available. Isolating this Python in a virtual environment is recommended to avoid interfering with your system Python.

**Install the Zephyr Software Development Kit (SDK)** Use of the Zephyr SDK is optional, but recommended. Some of the dependencies installed above are only needed for installing the SDK.

Zephyr's SDK (Software Development Kit) contains all necessary tools to build Zephyr on all supported architectures. Additionally, it includes host tools such as custom QEMU binaries and a host compiler. The SDK supports the following target architectures:

- X86 (Intel Architecture 32 bits)
- ARM (Advanced RISC Machine)
- ARC (Argonaut RISC Core)
- NIOS II
- RISC-V
- SPARC
- XTENSA

Follow these steps to install the Zephyr SDK:

1. Download the [latest SDK](#) as a self-extracting installation binary:

```
wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.13.1/  
→zephyr-sdk-0.13.1-linux-x86_64-setup.run
```

(You can change `0.13.1` to another version if needed; the [Zephyr Downloads](#) page contains all available SDK releases.)

2. Run the installation binary, installing the SDK at `~/zephyr-sdk-0.13.1`:

```
cd <sdk download directory>  
chmod +x zephyr-sdk-0.13.1-linux-x86_64-setup.run  
./zephyr-sdk-0.13.1-linux-x86_64-setup.run -- -d ~/zephyr-sdk-0.13.1
```

You can pick another directory if you want. If this fails, make sure Zephyr's dependencies were installed as described in [Install Requirements and Dependencies](#).

If you ever want to uninstall the SDK, just remove the directory where you installed it.

---

**Note:** It is recommended to install the Zephyr SDK at one of the following locations:

- `$HOME/zephyr-sdk[-x.y.z]`

- `$HOME/.local/zephyr-sdk[-x.y.z]`
- `$HOME/.local/opt/zephyr-sdk[-x.y.z]`
- `$HOME/bin/zephyr-sdk[-x.y.z]`
- `/opt/zephyr-sdk[-x.y.z]`
- `/usr/zephyr-sdk[-x.y.z]`
- `/usr/local/zephyr-sdk[-x.y.z]`

where `[-x.y.z]` is optional text, and can be any text, for example `-0.13.1`.

If you install the Zephyr SDK outside any of those locations, then it is required to register the Zephyr SDK in the CMake package registry during installation or set `ZEPHYR_SDK_INSTALL_DIR` to point to the Zephyr SDK installation folder.

`ZEPHYR_SDK_INSTALL_DIR` can also be used for pointing to a folder containing multiple Zephyr SDKs, allowing for automatic toolchain selection, for example: `ZEPHYR_SDK_INSTALL_DIR=/company/tools`

- `/company/tools/zephyr-sdk-0.13.1`
- `/company/tools/zephyr-sdk-a.b.c`
- `/company/tools/zephyr-sdk-x.y.z`

this allow Zephyr to pick the right toolchain, while allowing multiple Zephyr SDKs to be grouped together at a custom location.

---

**Building on Linux without the Zephyr SDK** The Zephyr SDK is provided for convenience and ease of use. It provides toolchains for all Zephyr target architectures, and does not require any extra flags when building applications or running tests. In addition to cross-compilers, the Zephyr SDK also provides pre-built host tools. It is, however, possible to build without the SDK's toolchain by using another toolchain as as described in the main [Getting Started Guide](#) document.

As already noted above, the SDK also includes prebuilt host tools. To use the SDK's prebuilt host tools with a toolchain from another source, you must set the `ZEPHYR_SDK_INSTALL_DIR` environment variable to the Zephyr SDK installation directory. To build without the Zephyr SDK's prebuilt host tools, the `ZEPHYR_SDK_INSTALL_DIR` environment variable must be unset.

To make sure this variable is unset, run:

```
unset ZEPHYR_SDK_INSTALL_DIR
```

## macOS alternative setup instructions

**Important note about Gatekeeper** Starting with macOS 10.15 Catalina, applications launched from the macOS Terminal application (or any other terminal emulator) are subject to the same system security policies that are applied to applications launched from the Dock. This means that if you download executable binaries using a web browser, macOS will not let you execute those from the Terminal by default. In order to get around this issue you can take two different approaches:

- Run `xattr -r -d com.apple.quarantine /path/to/folder` where `path/to/folder` is the path to the enclosing folder where the executables you want to run are located.
- Open "System Preferences" -> "Security and Privacy" -> "Privacy" and then scroll down to "Developer Tools". Then unlock the lock to be able to make changes and check the checkbox corresponding to your terminal emulator of choice. This will apply to any executable being launched from such terminal program.

Note that this section does **not** apply to executables installed with Homebrew, since those are automatically un-quarantined by brew itself. This is however relevant for most [3rd Party Toolchains](#).

**Additional notes for MacPorts users** While MacPorts is not officially supported in this guide, it is possible to use MacPorts instead of Homebrew to get all the required dependencies on macOS. Note also that you may need to install rust and cargo for the Python dependencies to install correctly.

### Windows alternative setup instructions

**Windows 10 WSL (Windows Subsystem for Linux)** If you are running a recent version of Windows 10 you can make use of the built-in functionality to natively run Ubuntu binaries directly on a standard command-prompt. This allows you to use software such as the [Zephyr SDK](#) without setting up a virtual machine.

**Warning:** Windows 10 version 1803 has an issue that will cause CMake to not work properly and is fixed in version 1809 (and later). More information can be found in [Zephyr Issue 10420](#)

1. Install the Windows Subsystem for Linux (WSL).

---

**Note:** For the Zephyr SDK to function properly you will need Windows 10 build 15002 or greater. You can check which Windows 10 build you are running in the “About your PC” section of the System Settings. If you are running an older Windows 10 build you might need to install the Creator’s Update.

---

2. Follow the Ubuntu instructions in the [Install Linux Host Dependencies](#) document.

### 8.1.3 Set Up a Toolchain

Zephyr binaries are compiled and linked by a *toolchain* comprised of a cross-compiler and related tools which are different than the compiler and tools used for developing software that runs natively on your operating system.

On Linux systems, you can install the [Zephyr SDK](#) to get toolchains for all supported architectures. Otherwise, you can install other toolchains in the usual way for your operating system: with installer programs or system package managers, by downloading and extracting a zip archive, etc.

You configure the Zephyr build system to use a specific toolchain by setting [environment variables](#) such as ZEPHYR\_TOOLCHAIN\_VARIANT to a supported value, along with additional variable(s) specific to the toolchain variant.

While the Zephyr SDK includes standard tool chains for all supported architectures, there are also customized alternatives as described in these documents. (If you’re not sure which to use, check your specific board-level documentation. If you’re targeting an Arm Cortex-M board, for example, [GNU ARM Embedded](#) is a safe bet.)

#### 3rd Party Toolchains

A “3rd party toolchain” is an officially supported toolchain provided by an external organization. Several of these are available.

#### GNU ARM Embedded

**Warning:** Do not install the toolchain into a path with spaces.

1. Download and install a [GNU ARM Embedded](#) build for your operating system and extract it on your file system.

---

**Note:** On Windows, we'll assume you install into the directory `C:\gnu_arm_embedded`.

---

**Warning:** On macOS Catalina or later you might need to [change a security policy](#) for the toolchain to be able to run from the terminal.

2. [Set these environment variables](#):
  - Set `ZEPHYR_TOOLCHAIN_VARIANT` to `gnuarmemb`.
  - Set `GNUARMEMB_TOOLCHAIN_PATH` to the toolchain installation directory.
3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `GNUARMEMB_TOOLCHAIN_PATH` values may be different on your system):

```
# Linux, macOS:
$ echo $ZEPHYR_TOOLCHAIN_VARIANT
gnuarmemb
$ echo $GNUARMEMB_TOOLCHAIN_PATH
/home/you/Downloads/gnu_arm_embedded

# Windows:
> echo %ZEPHYR_TOOLCHAIN_VARIANT%
gnuarmemb
> echo %GNUARMEMB_TOOLCHAIN_PATH%
C:\gnu_arm_embedded
```

**Warning:** On macOS, if you are having trouble with the suggested procedure, there is an unofficial package on brew that might help you. Run `brew install gcc-arm-embedded` and configure the variables

- Set `ZEPHYR_TOOLCHAIN_VARIANT` to `gnuarmemb`.
- Set `GNUARMEMB_TOOLCHAIN_PATH` to the brew installation directory (something like `/usr/local`)

## Intel oneAPI Toolkit

1. Download [Intel oneAPI Base Toolkit](#)
2. Assuming the toolkit is installed in `/opt/intel/oneapi`, set environment using:

```
# Linux, macOS:
export ONEAPI_TOOLCHAIN_PATH=/opt/intel/oneapi
source $ONEAPI_TOOLCHAIN_PATH/compiler/latest/env/vars.sh

# Windows:
> set ONEAPI_TOOLCHAIN_PATH=C:\Users\Intel\oneapi
```

To setup the complete oneApi environment, use:

```
source /opt/intel/oneapi/setvars.sh
```

The above will also change the python environment to the one used by the toolchain and might conflict with what Zephyr uses.

3. Set ZEPHYR\_TOOLCHAIN\_VARIANT to oneApi.

### DesignWare ARC MetaWare Development Toolkit (MWDT)

1. You need to have [ARC MWDT](#) installed on your host.
2. *Set these environment variables:*
  - Set ZEPHYR\_TOOLCHAIN\_VARIANT to arcmwdt.
  - Set ARCMWDT\_TOOLCHAIN\_PATH to the toolchain installation directory. MWDT installation provides METAWARE\_ROOT so simply set ARCMWDT\_TOOLCHAIN\_PATH to \$METAWARE\_ROOT/../../ (Linux) or %METAWARE\_ROOT%\..\ (Windows)
3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the ARCMWDT\_TOOLCHAIN\_PATH values may be different on your system):

```
# Linux:
$ echo $ZEPHYR_TOOLCHAIN_VARIANT
arcmwdt
$ echo $ARCMWDT_TOOLCHAIN_PATH
/home/you/ARC/MWDT_2019.12/

# Windows:
> echo %ZEPHYR_TOOLCHAIN_VARIANT%
arcmwdt
> echo %ARCMWDT_TOOLCHAIN_PATH%
C:\ARC\MWDT_2019.12\
```

**Crosstool-NG** You can build toolchains from source code using crosstool-NG.

1. Follow the steps on the crosstool-NG website to [prepare your host](#).
2. Follow the [Zephyr SDK with Crosstool NG instructions](#) to build your toolchain. Repeat as necessary to build toolchains for multiple target architectures.

You will need to clone the sdk-ng repo and run the following command:

```
./go.sh <arch>
```

---

**Note:** Currently, only i586 and Arm toolchain builds are verified.

---

3. *Set these environment variables:*
  - Set ZEPHYR\_TOOLCHAIN\_VARIANT to xtools.
  - Set XTOOLS\_TOOLCHAIN\_PATH to the toolchain build directory.
4. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the XTOOLS\_TOOLCHAIN\_PATH values may be different on your system):

```
# Linux, macOS:
$ echo $ZEPHYR_TOOLCHAIN_VARIANT
xtools
$ echo $XTOOLS_TOOLCHAIN_PATH
/Volumes/CrossToolNGNew/build/output/
```

## Other Cross Compilers

This toolchain variant is borrowed from the Linux kernel build system’s mechanism of using a `CROSS_COMPILE` environment variable to set up a GNU-based cross toolchain.

Examples of such “other cross compilers” are cross toolchains that your Linux distribution packaged, that you compiled on your own, or that you downloaded from the net. Unlike toolchains specifically listed in [3rd Party Toolchains](#), the Zephyr build system may not have been tested with them, and doesn’t officially support them. (Nonetheless, the toolchain set-up mechanism itself is supported.)

Follow these steps to use one of these toolchains.

1. Install a cross compiler suitable for your host and target systems.

For example, you might install the `gcc-arm-none-eabi` package on Debian-based Linux systems, or `arm-none-eabi-newlib` on Fedora or Red Hat:

```
# On Debian or Ubuntu
sudo apt-get install gcc-arm-none-eabi
# On Fedora or Red Hat
sudo dnf install arm-none-eabi-newlib
```

2. [Set these environment variables](#):

- Set `ZEPHYR_TOOLCHAIN_VARIANT` to `cross-compile`.
- Set `CROSS_COMPILE` to the common path prefix which your toolchain’s binaries have, e.g. the path to the directory containing the compiler binaries plus the target triplet and trailing dash.

3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `CROSS_COMPILE` value may be different on your system):

```
# Linux, macOS:
$ echo $ZEPHYR_TOOLCHAIN_VARIANT
cross-compile
$ echo $CROSS_COMPILE
/usr/bin/arm-none-eabi-
```

You can also set `CROSS_COMPILE` as a CMake variable.

When using this option, all of your toolchain binaries must reside in the same directory and have a common file name prefix. The `CROSS_COMPILE` variable is set to the directory concatenated with the file name prefix. In the Debian example above, the `gcc-arm-none-eabi` package installs binaries such as `arm-none-eabi-gcc` and `arm-none-eabi-ld` in directory `/usr/bin/`, so the common prefix is `/usr/bin/arm-none-eabi-` (including the trailing dash, `-`). If your toolchain is installed in `/opt/mytoolchain/bin` with binary names based on target triplet `myarch-none-elf`, `CROSS_COMPILE` would be set to `/opt/mytoolchain/bin/myarch-none-elf-`.

## Host Toolchains

In some specific configurations, like when building for non-MCU x86 targets on a Linux host, you may be able to re-use the native development tools provided by your operating system.

To use your host `gcc`, set the `ZEPHYR_TOOLCHAIN_VARIANT` [environment variable](#) to `host`. To use `clang`, set `ZEPHYR_TOOLCHAIN_VARIANT` to `llvm`.

## Custom CMake Toolchains

To use a custom toolchain defined in an external CMake file, [set these environment variables](#):

- Set `ZEPHYR_TOOLCHAIN_VARIANT` to your toolchain’s name

- Set `TOOLCHAIN_ROOT` to the path to the directory containing your toolchain's CMake configuration files.

Zephyr will then include the toolchain cmake files located in the `TOOLCHAIN_ROOT` directory:

- `cmake/toolchain/<toolchain name>/generic.cmake`: configures the toolchain for “generic” use, which mostly means running the C preprocessor on the generated [Devicetree](#) file.
- `cmake/toolchain/<toolchain name>/target.cmake`: configures the toolchain for “target” use, i.e. building Zephyr and your application's source code.

Here `<toolchain name>` is the same as the name provided in `ZEPHYR_TOOLCHAIN_VARIANT`. See the zephyr files `cmake/generic_toolchain.cmake` and `cmake/target_toolchain.cmake` for more details on what your `generic.cmake` and `target.cmake` files should contain.

You can also set `ZEPHYR_TOOLCHAIN_VARIANT` and `TOOLCHAIN_ROOT` as CMake variables when generating a build system for a Zephyr application, like so:

```
west build ... -- -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=...
```

```
cmake -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=...
```

If you do this, `-C <initial-cache>` [cmake option](#) may be useful. If you save your `ZEPHYR_TOOLCHAIN_VARIANT`, `TOOLCHAIN_ROOT`, and other settings in a file named `my-toolchain.cmake`, you can then invoke cmake as `cmake -C my-toolchain.cmake ...` to save typing.

Zephyr includes `include/toolchain.h` which again includes a toolchain specific header based on the compiler identifier, such as `__llvm__` or `__GNUC__`. Some custom compilers identify themselves as the compiler on which they are based, for example `llvm` which then gets the `toolchain/llvm.h` included. This included file may though not be right for the custom toolchain. In order to solve this, and thus to get the `include/other.h` included instead, add the `set(TOOLCHAIN_USE_CUSTOM 1)` cmake line to the `generic.cmake` and/or `target.cmake` files located under `<TOOLCHAIN_ROOT>/cmake/toolchain/<toolchain name>/`.

When `TOOLCHAIN_USE_CUSTOM` is set, the `other.h` must be available out-of-tree and it must include the correct header for the custom toolchain. A good location for the `other.h` header file, would be a directory under the directory specified in `TOOLCHAIN_ROOT` as `include/toolchain`. To get the toolchain header included in zephyr's build, the `USERINCLUDE` can be set to point to the include directory, as shown here:

```
west build -- -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=... -DUSERINCLUDE=...
```

### 8.1.4 Cloning the Zephyr Repositories

The Zephyr project source is maintained in the [GitHub zephyr repo](#). External modules used by Zephyr are found in the parent [GitHub Zephyr project](#). Because of these dependencies, it's convenient to use the Zephyr-created [west](#) tool to fetch and manage the Zephyr and external module source code. See [Basics](#) for more details.

Once your development tools are installed, use [West \(Zephyr's meta-tool\)](#) to create, initialize, and download sources from the zephyr and external module repos. We'll use the name `zephyrproject`, but you can choose any name that does not contain a space anywhere in the path.

```
west init zephyrproject
cd zephyrproject
west update
```

The `west update` command fetches and keeps [Modules \(External projects\)](#) in the `zephyrproject` folder in sync with the code in the local zephyr repo.

**Warning:** You must run `west update` any time the `zephyr/west.yml` changes, caused, for example, when you pull the zephyr repository, switch branches in it, or perform a `git bisect` inside of it.

## Keeping Zephyr updated

To update the Zephyr project source code, you need to get the latest changes via `git`. Afterwards, run `west update` as mentioned in the previous paragraph.

```
# replace zephyrproject with the path you gave west init
cd zephyrproject/zephyr
git pull
west update
```

### 8.1.5 Export Zephyr CMake package

The [Zephyr CMake Package](#) can be exported to CMake’s user package registry if it has not already been done as part of [Getting Started Guide](#).

### 8.1.6 Board Aliases

Developers who work with multiple boards may find explicit board names cumbersome and want to use aliases for common targets. This is supported by a CMake file with content like this:

```
# Variable foo_BOARD_ALIAS=bar replaces BOARD=foo with BOARD=bar and
# sets BOARD_ALIAS=foo in the CMake cache.
set(pca10028_BOARD_ALIAS nrf51dk_nrf51422)
set(pca10056_BOARD_ALIAS nrf52840dk_nrf52840)
set(k64f_BOARD_ALIAS frdm_k64f)
set(sltb004a_BOARD_ALIAS efr32mg_sltb004a)
```

and specifying its location in `ZEPHYR_BOARD_ALIASES`. This enables use of aliases `pca10028` in contexts like `cmake -DBOARD=pca10028` and `west -b pca10028`.

### 8.1.7 Build and Run an Application

You can build, flash, and run Zephyr applications on real hardware using a supported host system. Depending on your operating system, you can also run it in emulation with QEMU, or as a native POSIX application. Additional information about building applications can be found in the [Building an Application](#) section.

#### Build Blinky

Let’s build the `blinky-sample` application.

Zephyr applications are built to run on specific hardware, called a “board”<sup>2</sup>. We’ll use the `Phytec reel_board` here, but you can change the `reel_board` build target to another value if you have a different board. See `boards` or run `west boards` from anywhere inside the `zephyrproject` directory for a list of supported boards.

<sup>2</sup> This has become something of a misnomer over time. While the target can be, and often is, a microprocessor running on its own dedicated hardware board, Zephyr also supports using QEMU to run targets built for other architectures in emulation, targets which produce native host system binaries that implement Zephyr’s driver interfaces with POSIX APIs, and even running different Zephyr-based binaries on CPU cores of differing architectures on the same physical chip. Each of these hardware configurations is called a “board,” even though that doesn’t always make perfect sense in context.

1. Go to the zephyr repository:

```
cd zephyrproject/zephyr
```

2. Build the blinky sample for the reel\_board:

```
west build -b reel_board samples/basic/blinky
```

The main build products will be in `build/zephyr`; `build/zephyr/zephyr.elf` is the blinky application binary in ELF format. Other binary formats, disassembly, and map files may be present depending on your board.

The other sample applications in the [samples](#) folder are documented in [samples-and-demos](#).

---

**Note:** If you want to re-use an existing build directory for another board or application, you need to add the parameter `-p=auto` to `west build` to clean out settings and artifacts from the previous build.

---

## Run the Application by Flashing to a Board

Most hardware boards supported by Zephyr can be flashed by running `west flash`. This may require board-specific tool installation and configuration to work properly.

See [Run an Application](#) and your specific board's documentation in [boards](#) for additional details.

## Setting udev rules

Flashing a board requires permission to directly access the board hardware, usually managed by installation of the flashing tools. On Linux systems, if the `west flash` command fails, you likely need to define udev rules to grant the needed access permission.

Udev is a device manager for the Linux kernel and the udev daemon handles all user space events raised when a hardware device is added (or removed) from the system. We can add a rules file to grant access permission by non-root users to certain USB-connected devices.

The OpenOCD (On-Chip Debugger) project conveniently provides a rules file that defined board-specific rules for most Zephyr-supported arm-based boards, so we recommend installing this rules file by downloading it from their sourceforge repo, or if you've installed the Zephyr SDK there is a copy of this rules file in the SDK folder:

- Either download the OpenOCD rules file and copy it to the right location:

```
wget -O 60-openocd.rules https://sf.net/p/openocd/code/ci/master/tree/contrib/60-  
→openocd.rules?format=raw  
sudo cp 60-openocd.rules /etc/udev/rules.d
```

- or copy the rules file from the Zephyr SDK folder:

```
sudo cp ${ZEPHYR_SDK_INSTALL_DIR}/sysroots/x86_64-pokysdk-linux/usr/share/  
→openocd/contrib/60-openocd.rules /etc/udev/rules.d
```

Then, in either case, ask the udev daemon to reload these rules:

```
sudo udevadm control --reload
```

Unplug and plug in the USB connection to your board, and you should have permission to access the board hardware for flashing. Check your board-specific documentation ([boards](#)) for further information if needed.

## Run the Application in QEMU

On Linux and macOS, you can run Zephyr applications via emulation on your host system using [QEMU](#) when targeting either the x86 or ARM Cortex-M3 architectures. (QEMU is included with the Zephyr SDK installation.)

For example, you can build and run the `hello_world` sample using the x86 emulation board configuration (`qemu_x86`), with:

```
# From the root of the zephyr repository
west build -b qemu_x86 samples/hello_world
west build -t run
```

To exit QEMU, type `Ctrl-a`, then `x`.

Use `qemu_cortex_m3` to target an emulated Arm Cortex-M3 sample.

## Run a Sample Application natively (POSIX OS)

You can compile some samples to run as host processes on a POSIX OS. This is currently only tested on Linux hosts. See `native_posix` for more information. On 64-bit host operating systems, you need to install a 32-bit C library; see `native_posix_deps` for details.

First, build Hello World for `native_posix`.

```
# From the root of the zephyr repository
west build -b native_posix samples/hello_world
```

Next, run the application.

```
west build -t run
# or just run zephyr.exe directly:
./build/zephyr/zephyr.exe
```

Press `Ctrl-C` to exit.

You can run `./build/zephyr/zephyr.exe --help` to get a list of available options.

This executable can be instrumented using standard tools, such as `gdb` or `valgrind`.

## 8.2 Architecture-related Guides

### 8.2.1 Zephyr support status on ARC processors

#### Overview

This page describes current state of Zephyr for ARC processors and some future plans. Please note that

- plans are given without exact deadlines
- software features require corresponding hardware to be present and configured the proper way
- not all the features can be enabled at the same time

#### Support status

Legend: **Y** - yes, supported; **N** - no, not supported; **WIP** - Work In Progress; **TBD** - to be decided

	Processor families			
	EM	HS3x/4x	EV	HS6x
Port status	up-streamed	up-streamed	WIP	up-streamed
<b>Features</b>				
Closely coupled memories (ICCM, DCCM) <sup>1</sup>	Y	Y	TBD	TBD
Execution with caches - Instruction/Data, L1/L2 caches	Y	Y	Y	Y
Hardware-assisted unaligned memory access	Y <sup>2</sup>	Y	TBD	Y
Regular interrupts with multiple priority levels, direct interrupts	Y	Y	TBD	Y
Fast interrupts, separate register banks for fast interrupts	Y	Y	TBD	N
Hardware floating point unit (FPU)	Y	Y	N	TBD
Symmetric multiprocessing (SMP) support, switch-based	N/A	Y	TBD	WIP
Hardware-assisted stack checking	Y	Y	TBD	N
Hardware-assisted atomic operations	N/A	Y	TBD	Y
DSP ISA	Y	N <sup>3</sup>	TBD	TBD
DSP AGU/XY extensions	N <sup>Page 1472, 3</sup>	N <sup>Page 1472, 3</sup>	TBD	TBD
Userspace	Y	Y	N	TBD

## Notes

### 8.2.2 Arm Cortex-M Developer Guide

#### Overview

This page contains detailed information about the status of the Arm Cortex-M architecture porting in the Zephyr RTOS and describes key aspects when developing Zephyr applications for Arm Cortex-M-based platforms.

#### Key supported features

The table below summarizes the status of key OS features in the different Arm Cortex-M implementation variants.

<sup>1</sup> usage of CCMs is limited on SMP systems

<sup>2</sup> except the systems with secure features (SecureShield) due to HW limitation

<sup>3</sup> We only support save/restore ACCL/ACCH registers in task's context. Rest of DSP/AGU registers save/restore isn't implemented but kernel itself does not use these registers. This allows single task per core to use DSP/AGU safely.

<sup>4</sup> MetaWare toolchain supports building for ARCV3 HS6x, however, it's not integrated to Zephyr itself

<sup>5</sup> QEMU doesn't support all the ARC processor's HW features. For the detailed info please check the ARC QEMU documentation

Architecture variant		Processor families							
		Arm v6-M		Arm v7-M			Arm v8-M		Arm v8.1-M
		M0/M1	M0+	M3	M4	M7	M23	M33	M55
<b>OS Features</b>									
Programmable fault IRQ priorities		Y	N	Y	Y	Y	N	Y	Y
Single-thread kernel support		Y	Y	Y	Y	Y	Y	Y	Y
Thread local storage support		Y	Y	Y	Y	Y	Y	Y	Y
Interrupt handling									
	Regular interrupts	Y	Y	Y	Y	Y	Y	Y	Y
	Dynamic interrupts	Y	Y	Y	Y	Y	Y	Y	Y
	Direct interrupts	Y	Y	Y	Y	Y	Y	Y	Y
	Zero Latency interrupts	N	N	Y	Y	Y	Y	Y	Y
CPU idling		Y	Y	Y	Y	Y	Y	Y	Y
Native system timer (SysTick)		N <sup>1</sup>	Y	Y	Y	Y	Y	Y	Y
Memory protection									
	User mode	N	Y	Y	Y	Y	Y	Y	Y
	HW stack protection (MPU)	N	N	Y	Y	Y	Y	Y	Y
	HW-assisted stack limit checking	N	N	N	N	N	Y <sup>2</sup>	Y	Y
HW-assisted null-pointer dereference detection		N	N	Y	Y	Y	Y	Y	Y
HW-assisted atomic operations		N	N	Y	Y	Y	N	Y	Y
Support for non-cacheable regions		N	N	Y	Y	Y	N	Y	Y
Execute SRAM functions		N	N	Y	Y	Y	N	Y	Y
Floating Point Services		N	N	N	Y	Y	N	Y	Y
DSP ISA		N	N	N	Y	Y	N	Y	Y
Trusted-Execution									
	Native TrustZone-M support	N	N	N	N	N	Y	Y	Y
	TF-M integration	N	N	N	N	N	N	Y	N
Code relocation		Y	Y	Y	Y	Y	Y	Y	Y
SW-based vector table relaying		Y	Y	Y	Y	Y	Y	Y	Y
HW-assisted timing functions		N	N	Y	Y	Y	N	Y	Y

## Notes

<sup>1</sup> SysTick is optional in Cortex-M1

<sup>2</sup> Stack limit checking only in Secure builds in Cortex-M23

## OS features

### Threads

**Thread stack alignment** Each Zephyr thread is defined with its own stack memory. By default, Cortex-M enforces a double word thread stack alignment, see `:kconfig: `CONFIG_STACK_ALIGN_DOUBLE_WORD``. If MPU-based HW-assisted stack overflow detection (`:kconfig: `CONFIG_MPU_STACK_GUARD``) is enabled, thread stacks need to be aligned with a larger value, reflected by `:kconfig: `CONFIG_ARM_MPU_REGION_MIN_ALIGN_AND_SIZE``. In Arm v6-M and Arm v7-M architecture variants, thread stacks are additionally required to be align with a value equal to their size, in applications that need to support user mode (`:kconfig: `CONFIG_USERSPACE``). The thread stack sizes in that case need to be a power of two. This is all reflected by `:kconfig: `CONFIG_MPU_REQUIRES_POWER_OF_TWO_ALIGNMENT``, that is enforced in Arm v6-M and Arm v7-M builds with user mode support.

**Stack pointers** While executing in thread mode the processor is using the Process Stack Pointer (PSP). The processor uses the Main Stack Pointer (MSP) while executing in handler mode, that is, while servicing exceptions and HW interrupts. Using PSP in thread mode *facilitates thread stack pointer manipulation* during thread context switching, without affecting the current execution context flow in handler mode.

In Arm Cortex-M builds a single interrupt stack memory is shared among exceptions and interrupts. The size of the interrupt stack needs to be selected taking into consideration nested interrupts, each pushing an additional stack frame. Developers can modify the interrupt stack size using `:kconfig: `CONFIG_ISR_STACK_SIZE``.

The interrupt stack is also used during early boot so the kernel can initialize the main thread's stack before switching to the main thread.

**Thread context switching** In Arm Cortex-M builds, the PendSV exception is used in order to trigger a context switch to a different thread. PendSV exception is always present in Cortex-M implementations. PendSV is configured with the lowest possible interrupt priority level, in all Cortex-M variants. The main reasons for that design are

- to utilize the tail chaining feature of Cortex-M processors, and thus limit the number of context switch operations that occur.
- to not impact the interrupt latency observed by HW interrupts.

As a result, context switch in Cortex-M is non-atomic, i.e. it may be *preempted* by HW interrupts, however, a context-switch operation must be completed before a new thread context-switch may start.

Typically a thread context-switch will perform the following operations

- When switching-out the current thread, the processor stores
  - the callee-saved registers (R4 - R11) in the thread's container for callee-saved registers, which is located in kernel memory
  - the thread's current operation *mode*
    - \* user or privileged execution mode
    - \* presense of an active floating point context
    - \* the EXC\_RETURN value of the current handler context (PendSV)
  - the floating point callee-saved registers (S16 - S31) in the thread's container for FP callee-saved registers, if the current thread has an active FP context
  - the PSP of the current thread which points to the beginning of the current thread's exception stack frame. The latter contains the caller-saved context and the return address of the switched-out thread.

- When switching-in a new thread the processor
  - restores the new thread's callee-saved registers from the thread's container for callee-saved registers
  - restores the new thread's operation *mode*
  - restores the FP callee-saved registers if the switched-in thread had an active FP context before being switched-out
  - re-programs the dynamic MPU regions to allow a user thread access its stack and application memories, and/or programs a stack-overflow MPU guard at the bottom of the thread's privileged stack
  - restores the PSP for the incoming thread and re-programs the stack pointer limit register (if applicable, see `:kconfig: `CONFIG_BUILTIN_STACK_GUARD``)
  - optionally does a stack limit checking for the switched-in thread, if sentinel-based stack limit checking is enabled (see `:kconfig: `CONFIG_STACK_SENTINEL``).

PendSV exception return sequence restores the new thread's caller-saved registers and the return address, as part of unstacking the exception stack frame.

The implementation of the context-switch mechanism is present in `arch/arm/core/aarch32/swap_helper.S`.

**Stack limit checking (Arm v8-M)** Armv8-M and Armv8.1-M variants support stack limit checking using the MSPLIM and PSPLIM core registers. The feature is enabled when `:kconfig: `CONFIG_BUILTIN_STACK_GUARD`` is set. When stack limit checking is enabled, both the thread's privileged or user stack, as well as the interrupt stack are guarded by PSPLIM and MSPLIM registers, respectively. MSPLIM is configured *once* during kernel boot, while PSPLIM is re-programmed during every thread context-switch or during system calls, when the thread switches from using its default stack to using its privileged stack, and vice versa. PSPLIM re-programming

- has a relatively low runtime overhead (programming is done with MSR instructions)
- does not impact interrupt latency
- does not require any memory areas to be reserved for stack guards
- does not make use of MPU regions

It is, therefore, considered as a lightweight but very efficient stack overflow detection mechanism in Cortex-M applications.

Stack overflows trigger the dedicated UsageFault exception provided by Arm v8-M.

**Interrupt handling features** This section describes certain aspects around exception and interrupt handling in Arm Cortex-M.

**Interrupt priority levels** The number of available (configurable) interrupt priority levels is determined by the number of implemented interrupt priority bits in NVIC; this needs to be described for each Cortex-M platform using DeviceTree:

```
&nvic {
    arm,num-irq-priority-bits = <#priority-bits>;
};
```

**Reserved priority levels** A number of interrupt priority levels are reserved for the OS.

By design, system fault exceptions have the highest priority level. In *Baseline* Cortex-M, this is actually enforced by hardware, as HardFault is the only available processor fault exception, and its priority is higher than any configurable exception priority.

In *Mainline* Cortex-M, the available fault exceptions (e.g. MemManageFault, UsageFault, etc.) are assigned the highest *configurable* priority level. (**:kconfig: `CONFIG\_CPU\_CORTEX\_M\_HAS\_PROGRAMMABLE\_FAULT\_PRIOS`** signifies explicitly that the Cortex-M implementation supports configurable fault priorities.)

This priority level is never shared with HW interrupts (an exception to this rule is described below). As a result, processor faults occurring in regular ISRs will be handled by the corresponding fault handler and will not escalate to a HardFault, *similar to processor faults occurring in thread mode*.

SVC exception is normally configured with the highest configurable priority level (an exception to this rule will be described below). SVCs are used by the Zephyr kernel to dispatch system calls, trigger runtime system errors (e.g. Kernel oops or panic), or implement IRQ offloading.

In *Baseline* Cortex-M the priority level of SVC may be shared with other exceptions or HW interrupts that are also given the highest configurable priority level (As a result of this, kernel runtime errors during interrupt handling will escalate to HardFault. Additional logic in the fault handling routines ensures that such runtime errors are detected successfully).

In *Mainline* Cortex-M, however, the SVC priority level is *reserved*, thus normally it is only shared with the fault exceptions of configurable priority. This simplifies the fault handling routines in *Mainline* Cortex-M architecture, since runtime kernel errors are serviced by the SVC handler (i.e no HardFault escalation, even if the kernel errors occur in ISR context).

HW interrupts in *Mainline* Cortex-M builds are allocated a priority level lower than the SVC.

One exception to the above rules is when Zephyr applications support Zero Latency Interrupts (ZLIs). Such interrupts are designed to have a priority level higher than any HW or system interrupt. If the ZLI feature is enabled in *Mainline* Cortex-M builds (see **:kconfig: `CONFIG\_ZERO\_LATENCY\_IRQS`**), then

- ZLIs are assigned the highest configurable priority level
- SVCs are assigned the second highest configurable priority level
- Regular HW interrupts are assigned priority levels lower than SVC.

The priority level configuration in Cortex-M is implemented in `include/arch/arm/aarch32/exc.h`.

**Locking and unlocking IRQs** In *Baseline* Cortex-M locking interrupts is implemented using the PRIMASK register.

```
arch_irq_lock()
```

will set the PRIMASK register to 1, eventually, masking all IRQs with configurable priority. While this fulfils the OS requirement of locking interrupts, the consequence is that kernel runtime errors (triggering SVCs) will escalate to HardFault.

In *Mainline* Cortex-M locking interrupts is implemented using the BASEPRI register (*Mainline* Cortex-M builds select **:kconfig: `CONFIG\_CPU\_CORTEX\_M\_HAS\_BASEPRI`** to signify that BASEPRI register is implemented.). By modifying BASEPRI (or BASEPRI\_MAX) `arch_irq_lock()` masks all system and HW interrupts with the exception of

- SVCs
- processor faults
- ZLIs

This allows zero latency interrupts to be triggered inside OS critical sections. Additionally, this allows system (processor and kernel) faults to be handled by Zephyr in *exactly the same way*, regardless of

whether IRQs have been locked or not when the error occurs. It also allows for system calls to be dispatched while IRQs are locked.

---

**Note:** Mainline Cortex-M fault handling is designed and configured in a way that all processor and kernel faults are handled by the corresponding exception handlers and never result in HardFault escalation. In other words, a HardFault may only occur in Zephyr applications that have modified the default fault handling configurations. The main reason for this design was to reserve the HardFault exception for handling exceptional error conditions in safety critical applications.

---

**Dynamic direct interrupts** Cortex-M builds support the installation of direct interrupt service routines during runtime. Direct interrupts are designed for performance-critical interrupt handling and do not go through all of the common Zephyr interrupt handling code.

Direct dynamic interrupts are enabled via switching on `:kconfig: `CONFIG_DYNAMIC_DIRECT_INTERRUPTS``.

Note that enabling direct dynamic interrupts requires enabling support for dynamic interrupts in the kernel, as well (see `:kconfig: `CONFIG_DYNAMIC_INTERRUPTS``).

**Zero Latency interrupts** As described above, in Mainline Cortex-M applications, the Zephyr kernel reserves the highest configurable interrupt priority level for its own use (SVC). SVCs will not be masked by interrupt locking. Zero-latency interrupt can be used to set up an interrupt at the highest interrupt priority which will not be blocked by interrupt locking. To use the ZLI feature `:kconfig: `CONFIG_ZERO_LATENCY_IRQS`` needs to be enabled.

Zero latency IRQs have minimal interrupt latency, as they will always preempt regular HW or system interrupts.

Note, however, that since ZLI ISRs will run at a priority level higher than the kernel exceptions they **cannot use** any kernel functionality. Additionally, since the ZLI interrupt priority level is equal to processor fault priority level, faults occurring in ZLI ISRs will escalate to HardFault and will not be handled in the same way as regular processor faults. Developers need to be aware of this limitation.

**CPU Idling** The Cortex-M architecture port implements both `k_cpu_idle()` and `k_cpu_atomic_idle()`. The implementation is present in `arch/arm/core/aarch32/cpu_idle.S`.

In both implementations, the processor will attempt to put the core to low power mode. In `k_cpu_idle()` the processor ends up executing WFI (Wait For Interrupt) instruction, while in `k_cpu_atomic_idle()` the processor will execute a WFE (Wait For Event) instruction.

When using the CPU idling API in Cortex-M it is important to note the following:

- Both `k_cpu_idle()` and `k_cpu_atomic_idle()` are *assumed* to be invoked with interrupts locked. This is taken care of by the kernel if the APIs are called by the idle thread.
- After waking up from low power mode, both functions will *restore* interrupts unconditionally, that is, regardless of the interrupt lock status before the CPU idle API was called.

The Zephyr CPU Idling mechanism is detailed in [CPU Idling](#).

**Memory protection features** This section describes certain aspects around memory protection features in Arm Cortex-M applications.

**User mode system calls** User mode is supported in Cortex-M platforms that implement the standard (Arm) MPU or a similar core peripheral logic for memory access policy configuration and control, such as the NXP MPU for Kinetis platforms. (Currently, `:kconfig: `CONFIG_ARCH_HAS_USERSPACE`` is selected if `:kconfig: `CONFIG_ARM_MPU`` is enabled by the user in the board default Kconfig settings).

A thread performs a system call by triggering a (synchronous) SVC exception, where

- up to 5 arguments are placed on registers R1 - R5
- system call ID is placed on register R6.

The SVC Handler will branch to the system call preparation logic, which will perform the following operations

- switch the thread's PSP to point to the beginning of the thread's privileged stack area, optionally reprogramming the PSPLIM if stack limit checking is enabled
- modify CONTROL register to switch to privileged mode
- modify the return address in the SVC exception stack frame, so that after exception return the system call dispatcher is executed (in thread privileged mode)

Once the system call execution is completed the system call dispatcher will restore the user's original PSP and PSPLIM and switch the CONTROL register back to unprivileged mode before returning back to the caller of the system call.

System calls execute in thread mode and can be preempted by interrupts at any time. A thread may also be context-switched-out while doing a system call; the system call will resume as soon as the thread is switched-in again.

The system call dispatcher executes at SVC priority, therefore it cannot be preempted by HW interrupts (with the exception of ZLIs), which may observe some additional interrupt latency if they occur during a system call preparation.

**MPU-assisted stack overflow detection** Cortex-M platforms with MPU may enable `:kconfig: `CONFIG_MPU_STACK_GUARD`` to enable the MPU-based stack overflow detection mechanism. The following points need to be considered when enabling the MPU stack guards

- stack overflows are triggering processor faults as soon as they occur
- the mechanism is essential for detecting stack overflows in supervisor threads, or user threads in privileged mode; stack overflows in threads in user mode will always be detected regardless of `:kconfig: `CONFIG_MPU_STACK_GUARD`` being set.
- stack overflows are always detected, however, the mechanism does not guarantee that no memory corruption occurs when supervisor threads overflow their stack memory
- `:kconfig: `CONFIG_MPU_STACK_GUARD`` will normally reserve one MPU region for programming the stack guard (in certain Arm v8-M configurations with `:kconfig: `CONFIG_MPU_GAP_FILLING`` enabled 2 MPU regions are required to implement the guard feature)
- MPU guards are re-programmed at every context-switch, adding a small overhead to the thread swap routine. Compared, however, to the `:kconfig: `CONFIG_BUILTIN_STACK_GUARD`` feature, no re-programming occurs during system calls.
- When `:kconfig: `CONFIG_HW_STACK_PROTECTION`` is enabled on Arm v8-M platforms the native stack limit checking mechanism is used by default instead of the MPU-based stack overflow detection mechanism; users may override this setting by manually enabling `:kconfig: `CONFIG_MPU_STACK_GUARD`` in these scenarios.

## Memory map and MPU considerations

**Fixed MPU regions** By default, when `:kconfig: `CONFIG_ARM_MPU`` is enabled a set of *fixed* MPU regions are programmed during system boot.

- One MPU region programs the entire flash area as read-execute. User can override this setting by enabling `:kconfig: `CONFIG_MPU_ALLOW_FLASH_WRITE``, which programs the flash with RWX

permissions. If `:kconfig: `CONFIG_USERSPACE`` is enabled unprivileged access on the entire flash area is allowed.

- One MPU region programs the entire SRAM area with privileged-only RW permissions. That is, an MPU region is utilized to disallow execute permissions on SRAM. (An exception to this setting is when `:kconfig: `CONFIG_MPU_GAP_FILLING`` is disabled (Arm v8-M only); in that case no SRAM MPU programming is done so the access is determined by the default Arm memory map policies, allowing for privileged-only RWX permissions on SRAM).

The above MPU regions are defined in `soc/arm/common/arm_mpu_regions.c`. Alternative MPU configurations are allowed by enabling `:kconfig: `CONFIG_CPU_HAS_CUSTOM_FIXED_SOC_MPU_REGIONS``. When enabled, this option signifies that the Cortex-M SoC will define and configure its own fixed MPU regions in the SoC definition.

**Static MPU regions** Additional *static* MPU regions may be programmed once during system boot. These regions are required to enable certain features

- a RX region to allow execution from SRAM, when `:kconfig: `CONFIG_ARCH_HAS_RAMFUNC_SUPPORT`` is enabled and users have defined functions to execute from SRAM.
- a RX region for relocating text sections to SRAM, when `:kconfig: `CONFIG_CODE_DATA_RELOCATION_SRAM`` is enabled
- a no-cache region to allow for a none-cacheable SRAM area, when `:kconfig: `CONFIG_NOCACHE_MEMORY`` is enabled
- a possibly unprivileged RW region for GCOV code coverage accounting area, when `:kconfig: `CONFIG_COVERAGE_GCOV`` is enabled
- a no-access region to implement null pointer dereference detection, when `:kconfig: `CONFIG_NULL_POINTER_EXCEPTION_DETECTION_MPU`` is enabled

The boundaries of these static MPU regions are derived from symbols exposed by the linker, in `include/linker/linker-defs.h`.

**Dynamic MPU regions** Certain thread-specific MPU regions may be re-programmed dynamically, at each thread context switch:

- an unprivileged RW region for the current thread's stack area (for user threads)
- a read-only region for the MPU stack guard
- unprivileged RW regions for the partitions of the current thread's application memory domain.

**Considerations** The number of available MPU regions for a Cortex-M platform is a limited resource. Most platforms have 8 MPU regions, while some Cortex-M33 or Cortex-M7 platforms may have up to 16 MPU regions. Therefore there is a relatively strict limitation on how many fixed, static and dynamic MPU regions may be programmed simultaneously. For platforms with 8 available MPU regions it might not be possible to enable all the aforementioned features that require MPU region programming. In most practical applications, however, only a certain set of features is required and 8 MPU regions are, in many cases, sufficient.

In Arm v8-M processors the MPU architecture does not allow programmed MPU regions to overlap. `:kconfig: `CONFIG_MPU_GAP_FILLING`` controls whether the fixed MPU region covering the entire SRAM is programmed. When it does, a full SRAM area partitioning is required, in order to program the static and the dynamic MPU regions. This increases the total number of required MPU regions. When `:kconfig: `CONFIG_MPU_GAP_FILLING`` is not enabled the fixed MPU region covering the entire SRAM is not programmed, thus, the static and dynamic regions are simply programmed on top of the always-existing background region (full-SRAM partitioning is not required).

Note, however, that the background SRAM region allows execution from SRAM, so when `:kconfig: `CONFIG_MPU_GAP_FILLING`` is not set Zephyr is not protected against attacks that attempt to execute malicious code from SRAM.

**Floating point Services** Both unshared and shared FP registers mode are supported in Cortex-M (see [Floating Point Services](#) for more details).

When FPU support is enabled in the build (`:kconfig: `CONFIG_FPU`` is enabled), the sharing FP registers mode (`:kconfig: `CONFIG_FPU_SHARING``) is enabled by default. This is done as some compiler configurations may activate a floating point context by generating FP instructions for any thread, regardless of whether floating point calculations are performed, and that context must be preserved when switching such threads in and out.

The developers can still disable the FP sharing mode in their application projects, and switch to Unshared FP registers mode, if it is guaranteed that the image code does not generate FP instructions outside the single thread context that is allowed (and supposed) to do so.

Under FPU sharing mode, the callee-saved FPU registers are saved and restored in context-switch, if the corresponding threads have an active FP context. This adds some runtime overhead on the swap routine. In addition to the runtime overhead, the sharing FPU mode

- requires additional memory for each thread to save the callee-saved FP registers
- requires additional stack memory for each thread, to stack the caller-saved FP registers, upon exception entry, if an FP context is active. Note, however, that since lazy stacking is enabled, there is no runtime overhead of FP context stacking in regular interrupts (FP state preservation is only activated in the swap routine in PendSV interrupt).

## Misc

**Chain-loadable images** Cortex-M applications may either be standalone images or chain-loadable, for instance, by a bootloader. Application images chain-loadable by bootloaders (or other applications) normally occupy a specific area in the flash denoted as their *code partition*. `:kconfig: `CONFIG_USE_DT_CODE_PARTITION`` will ensure that a Zephyr chain-loadable image will be linked into its code partition, specified in DeviceTree.

**HW initialization at boot** In order to boot properly, chain-loaded applications may require that the core Arm hardware registers and peripherals are initialized in their reset values. Enabling `:kconfig: `CONFIG_INIT_ARCH_HW_AT_BOOT`` Zephyr to force the initialization of the internal Cortex-M architectural state during boot to the reset values as specified by the corresponding Arm architecture manual.

**Software vector relaying** In Cortex-M platforms that implement the VTOR register (see `:kconfig: `CONFIG_CPU_CORTEX_M_HAS_VTOR``), chain-loadable images relocate the Cortex-M vector table by updating the VTOR register with the offset of the image vector table.

Baseline Cortex-M platforms without VTOR register might not be able to relocate their vector table which remains at a fixed location. Therefore, a chain-loadable image will require an alternative way to route HW interrupts and system exceptions to its own vector table; this is achieved with software vector relaying.

When a bootloader image enables `:kconfig: `CONFIG_SW_VECTOR_RELAY`` it is able to relay exceptions and interrupts based on a vector table pointer that is set by the chain-loadable application. The latter sets the `:kconfig: `CONFIG_SW_VECTOR_RELAY_CLIENT`` option to instruct the boot sequence to set the vector table pointer in SRAM so that the bootloader can forward the exceptions and interrupts to the chain-loadable image's software vector table.

While this feature is intended for processors without VTOR register, it may also be used in Mainline Cortex-M platforms.

**Code relocation** Cortex-M support the code relocation feature. When `:kconfig: `CONFIG_CODE_DATA_RELOCATION_SRAM`` is selected, Zephyr will relocate .text, data and .bss sections from the specified files and place it in SRAM. It is possible to relocate only parts of the code sections into SRAM, without relocating the whole image text and data sections. More details on the code relocation feature can be found in [Code And Data Relocation](#).

## Linking Cortex-M applications

Most Cortex-M platforms make use of the default Cortex-M GCC linker script in `include/arch/arm/aarch32/cortex-m/scripts/linked.ld`, although it is possible for platforms to use a custom linker script as well.

## CMSIS

Cortex-M CMSIS headers are hosted in a standalone module repository: [zephyrproject-rtos/cmsis](#).

`:kconfig: `CONFIG_CPU_CORTEX_M`` selects `:kconfig: `CONFIG_HAS_CMSIS_CORE`` to signify that CMSIS headers are available for all supported Cortex-M variants.

## Testing

A list of unit tests for the Cortex-M porting and miscellaneous features is present in `tests/arch/arm/`. The tests suites are continuously extended and new test suites are added, in an effort to increase the coverage of the Cortex-M architecture support in Zephyr.

## QEMU

We use QEMU to verify the implemented features of the Cortex-M architecture port in Zephyr. Adequate coverage is achieved by defining and utilizing a list of QEMU targets, each with a specific architecture variant and Arm peripheral support list.

The table below lists the QEMU platform targets defined in Zephyr along with the corresponding Cortex-M implementation variant and the peripherals these targets emulate.

	QEMU target				
	Arm v6-M	Arm v7-M		Arm v8-M	Arm v8.1-M
Architecture variant	<code>qemu_cortex_m0</code>	<code>qemu_cortex_m3</code>	<code>mps2_an385</code>	<code>mps2_an521</code>	<code>mps3_an547</code>
Emulated features					
NVIC	Y	Y	Y	Y	Y
BASEPRI	N	Y	Y	Y	Y
SysTick	N	Y	Y	Y	Y
MPU	N	N	Y	Y	Y
FPU	N	N	N	Y	N
SPLIM	N	N	N	Y	Y
TrustZone-M	N	N	N	Y	N

## Maintainers & Collaborators

The status of the Arm Cortex-M architecture port in Zephyr is: *maintained*. The updated list of maintainers and collaborators for Cortex-M can be found in `MAINTAINERS.yml`.

## 8.2.3 x86 Developer Guide

### Overview

This page contains information on certain aspects when developing for x86-based platforms.

### Virtual Memory

During very early boot, page tables are loaded so technically the kernel is executing in virtual address space. By default, physical and virtual memory are identity mapped and thus giving the appearance of execution taking place in physical address space. The physical address space is marked by kconfig `:kconfig: `CONFIG_SRAM_BASE_ADDRESS`` and `:kconfig: `CONFIG_SRAM_SIZE`` while the virtual address space is marked by `:kconfig: `CONFIG_KERNEL_VM_BASE`` and `:kconfig: `CONFIG_KERNEL_VM_SIZE``. Note that `:kconfig: `CONFIG_SRAM_OFFSET`` controls where the Zephyr kernel is being placed in the memory, and its counterpart `:kconfig: `CONFIG_KERNEL_VM_OFFSET``.

**Separate Virtual Address Space from Physical Address Space** On 32-bit x86, it is possible to have separate physical and virtual address space. Code and data are linked in virtual address space, but are still loaded in physical memory. However, during boot, code and data must be available and also addressable in physical address space before `vm_enter` inside `arch/x86/core/ia32/crt0.S`. After `vm_enter`, code execution is done via virtual addresses and data can be referred via their virtual addresses. This is possible as the page table generation script (`arch/x86/gen_mmu.py`) identity maps the physical addresses at the page directory level, in addition to mapping virtual addresses to the physical memory. Later in the boot process, the entries for identity mapping at the page directory level are cleared in `z_x86_mmu_init()`, effectively removing the identity mapping of physical memory. This unmapping must be done for userspace isolation or else they would be able to access restricted memory via physical addresses. Since the identity mapping is done at the page directory level, there is no need to allocate additional space for the page table. However, additional space may still be required for additional page directory table.

There are restrictions on where virtual address space can be:

- Physical and virtual address spaces must be disjoint. This is required as the entries in page directory table will be cleared. If they are not disjoint, it would clear the entries needed for virtual addresses.
  - If `:kconfig: `CONFIG_X86_PAE`` is enabled (`=y`), each address space must reside in their own 1GB region, due to each entry of PDP (Page Directory Pointer) covers 1GB of memory. For example:
    - Assuming `CONFIG_SRAM_OFFSET` and `CONFIG_KERNEL_VM_OFFSET` are both `0x0`.
    - `CONFIG_SRAM_BASE_ADDRESS == 0x00000000` and `CONFIG_KERNEL_VM_BASE == 0x40000000` is valid, while
    - `CONFIG_SRAM_BASE_ADDRESS == 0x00000000` and `CONFIG_KERNEL_VM_BASE == 0x20000000` is not.
  - If `:kconfig: `CONFIG_X86_PAE`` is disabled (`=n`), each address space must reside in their own 4MB region, due to each entry of PD (Page Directory) covers 4MB of memory.
  - Both `CONFIG_SRAM_BASE_ADDRESS` and `CONFIG_KERNEL_VM_BASE` must also align with the starting addresses of targeted regions.

### Specifying Additional Memory Mappings at Build Time

The page table generation script (`arch/x86/gen_mmu.py`) generates the necessary multi-level page tables for code execution and data access using the kernel image produced by the first linker pass. Additional command line arguments can be passed to the script to generate additional memory mappings. This is

useful for static mappings and/or device MMIO access during very early boot. To pass extra command line arguments to the script, populate a CMake list named `X86_EXTRA_GEN_MMU_ARGUMENTS` in the board configuration file. Here is an example:

```
set(X86_EXTRA_GEN_MMU_ARGUMENTS
  --map 0xA0000000,0x2000
  --map 0x80000000,0x400000,LWUX,0xB0000000)
```

The argument `--map` takes the following value: `<physical address>,<size>[,<flags:LWUX>[,<virtual address>]]`, where:

- `<physical address>` is the physical address of the mapping. (Required)
- `<size>` is the size of the region to be mapped. (Required)
- `<flags>` is the flag associated with the mapping: (Optional)
  - L: Large page at the page directory level.
  - U: Allow userspace access.
  - W: Read/write.
  - X: Allow execution.
  - D: Cache disabled.
- `<virtual address>` is the virtual address of the mapping. (Optional)
  - \* Default is small page (4KB), supervisor only, read only, and execution disabled.

Note that specifying additional memory mappings requires larger storage space for the pre-allocated page tables (both kernel and per-domain tables). **:kconfig: `CONFIG_X86_EXTRA_PAGE_TABLE_PAGES`** is needed to specify how many more memory pages to be reserved for the page tables. If the needed space is not exactly the same as required space, the `gen_mmu.py` script will print out a message indicating what needs to be the value for the `kconfig`.

## 8.3 Bluetooth

This section contains information regarding the Bluetooth stack of the Zephyr OS. You can use this information to understand the principles behind the operation of the layers and how they were implemented.

Zephyr includes a complete Bluetooth Low Energy stack from application to radio hardware, as well as portions of a Classical Bluetooth (BR/EDR) Host layer.

### 8.3.1 Overview

#### • *Supported Features*

Since its inception, Zephyr has had a strong focus on Bluetooth and, in particular, on Bluetooth Low Energy (BLE). Through the contributions of several companies and individuals involved in existing open source implementations of the Bluetooth specification (Linux's BlueZ) as well as the design and development of BLE radio hardware, the protocol stack in Zephyr has grown to be mature and feature-rich, as can be seen in the section below.

#### Supported Features

Zephyr comes integrated with a feature-rich and highly configurable Bluetooth stack.

- Bluetooth 5.0 compliant (ESR10)

- Highly configurable
  - \* Features, buffer sizes/counts, stack sizes, etc.
- Portable to all architectures supported by Zephyr (including big and little endian, alignment flavors and more)
- Support for all combinations of Host and Controller builds:
  - \* Controller-only (HCI) over UART, SPI, and USB physical transports
  - \* Host-only over UART, SPI, and IPM (shared memory)
  - \* Combined (Host + Controller)
- Bluetooth-SIG qualified
  - Controller on Nordic Semiconductor hardware
  - Conformance tests run regularly on all layers
- Bluetooth Low Energy Controller support (LE Link Layer)
  - Unlimited role and connection count, all roles supported
  - Concurrent multi-protocol support ready
  - Intelligent scheduling of roles to minimize overlap
  - Portable design to any open BLE radio, currently supports Nordic Semiconductor nRF51 and nRF52, as well as proprietary radios
  - Supports little and big endian architectures, and abstracts the hard real-time specifics so that they can be encapsulated in a hardware-specific module
  - Support for Controller (HCI) builds over different physical transports
- Bluetooth Host support
  - Generic Access Profile (GAP) with all possible LE roles
    - \* Peripheral & Central
    - \* Observer & Broadcaster
  - GATT (Generic Attribute Profile)
    - \* Server (to be a sensor)
    - \* Client (to connect to sensors)
  - Pairing support, including the Secure Connections feature from Bluetooth 4.2
  - Non-volatile storage support for permanent storage of Bluetooth-specific settings and data
  - Bluetooth mesh support
    - \* Relay, Friend Node, Low-Power Node (LPN) and GATT Proxy features
    - \* Both Provisioning bearers supported (PB-ADV & PB-GATT)
    - \* Highly configurable, fits as small as 16k RAM devices
  - IPSP/6LoWPAN for IPv6 connectivity over Bluetooth LE
    - \* IPSP node sample application
  - Basic Bluetooth BR/EDR (Classic) support
    - \* Generic Access Profile (GAP)
    - \* Logical Link Control and Adaptation Protocol (L2CAP)
    - \* Serial Port emulation (RFCOMM protocol)
    - \* Service Discovery Protocol (SDP)

- Clean HCI driver abstraction
  - \* 3-Wire (H:5) & 5-Wire (H:4) UART
  - \* SPI
  - \* Local controller support as a virtual HCI driver
- Verified with multiple popular controllers

### 8.3.2 Bluetooth Stack Architecture

#### Overview

This page describes the software architecture of Zephyr's Bluetooth protocol stack.

---

**Note:** Zephyr supports mainly Bluetooth Low Energy (BLE), the low-power version of the Bluetooth specification. Zephyr also has limited support for portions of the BR/EDR Host. Throughout this architecture document we use BLE interchangeably for Bluetooth except when noted.

---

**BLE Layers** There are 3 main layers that together constitute a full Bluetooth Low Energy protocol stack:

- **Host:** This layer sits right below the application, and is comprised of multiple (non real-time) network and transport protocols enabling applications to communicate with peer devices in a standard and interoperable way.
- **Controller:** The Controller implements the Link Layer (LE LL), the low-level, real-time protocol which provides, in conjunction with the Radio Hardware, standard interoperable over the air communication. The LL schedules packet reception and transmission, guarantees the delivery of data, and handles all the LL control procedures.
- **Radio Hardware:** Hardware implements the required analog and digital baseband functional blocks that permit the Link Layer firmware to send and receive in the 2.4GHz band of the spectrum.

**Host Controller Interface** The [Bluetooth Specification](#) describes the format in which a Host must communicate with a Controller. This is called the Host Controller Interface (HCI) protocol. HCI can be implemented over a range of different physical transports like UART, SPI, or USB. This protocol defines the commands that a Host can send to a Controller and the events that it can expect in return, and also the format for user and protocol data that needs to go over the air. The HCI ensures that different Host and Controller implementations can communicate in a standard way making it possible to combine Hosts and Controllers from different vendors.

**Configurations** The three separate layers of the protocol and the standardized interface make it possible to implement the Host and Controller on different platforms. The two following configurations are commonly used:

- **Single-chip configuration:** In this configuration, a single microcontroller implements all three layers and the application itself. This can also be called a system-on-chip (SoC) implementation. In this case the BLE Host and the BLE Controller communicate directly through function calls and queues in RAM. The Bluetooth specification does not specify how HCI is implemented in this single-chip configuration and so how HCI commands, events, and data flows between the two can be implementation-specific. This configuration is well suited for those applications and designs that require a small footprint and the lowest possible power consumption, since everything runs on a single IC.
- **Dual-chip configuration:** This configuration uses two separate ICs, one running the Application and the Host, and a second one with the Controller and the Radio Hardware. This is sometimes

also called a connectivity-chip configuration. This configuration allows for a wider variety of combinations of Hosts when using the Zephyr OS as a Controller. Since HCI ensures interoperability among Host and Controller implementations, including of course Zephyr's very own BLE Host and Controller, users of the Zephyr Controller can choose to use whatever Host running on any platform they prefer. For example, the host can be the Linux BLE Host stack (BlueZ) running on any processor capable of supporting Linux. The Host processor may of course also run Zephyr and the Zephyr OS BLE Host. Conversely, combining an IC running the Zephyr Host with an external Controller that does not run Zephyr is also supported.

**Build Types** The Zephyr software stack as an RTOS is highly configurable, and in particular, the BLE subsystem can be configured in multiple ways during the build process to include only the features and layers that are required to reduce RAM and ROM footprint as well as power consumption. Here's a short list of the different BLE-enabled builds that can be produced from the Zephyr project codebase:

- **Controller-only build:** When built as a BLE Controller, Zephyr includes the Link Layer and a special application. This application is different depending on the physical transport chosen for HCI:
  - hci\_uart
  - hci\_usb
  - hci\_spi

This application acts as a bridge between the UART, SPI or USB peripherals and the Controller subsystem, listening for HCI commands, sending application data and responding with events and received data. A build of this type sets the following Kconfig option values:

- `:kconfig: `CONFIG_BT` =y`
  - `:kconfig: `CONFIG_BT_HCI` =y`
  - `:kconfig: `CONFIG_BT_HCI_RAW` =y`
  - `:kconfig: `CONFIG_BT_CTLR` =y`
  - `:kconfig: `CONFIG_BT_LL_SW_SPLIT` =y` (if using the open source Link Layer)
- **Host-only build:** A Zephyr OS Host build will contain the Application and the BLE Host, along with an HCI driver (UART or SPI) to interface with an external Controller chip. A build of this type sets the following Kconfig option values:
    - `:kconfig: `CONFIG_BT` =y`
    - `:kconfig: `CONFIG_BT_HCI` =y`
    - `:kconfig: `CONFIG_BT_CTLR` =n`

All of the samples located in `samples/bluetooth` except for the ones used for Controller-only builds can be built as Host-only

- **Combined build:** This includes the Application, the Host and the Controller, and it is used exclusively for single-chip (SoC) configurations. A build of this type sets the following Kconfig option values:
  - `:kconfig: `CONFIG_BT` =y`
  - `:kconfig: `CONFIG_BT_HCI` =y`
  - `:kconfig: `CONFIG_BT_CTLR` =y`
  - `:kconfig: `CONFIG_BT_LL_SW_SPLIT` =y` (if using the open source Link Layer)

All of the samples located in `samples/bluetooth` except for the ones used for Controller-only builds can be built as Combined

The picture below shows the SoC or single-chip configuration when using a Zephyr combined build (a build that includes both a BLE Host and a Controller in the same firmware image that is programmed onto the chip):

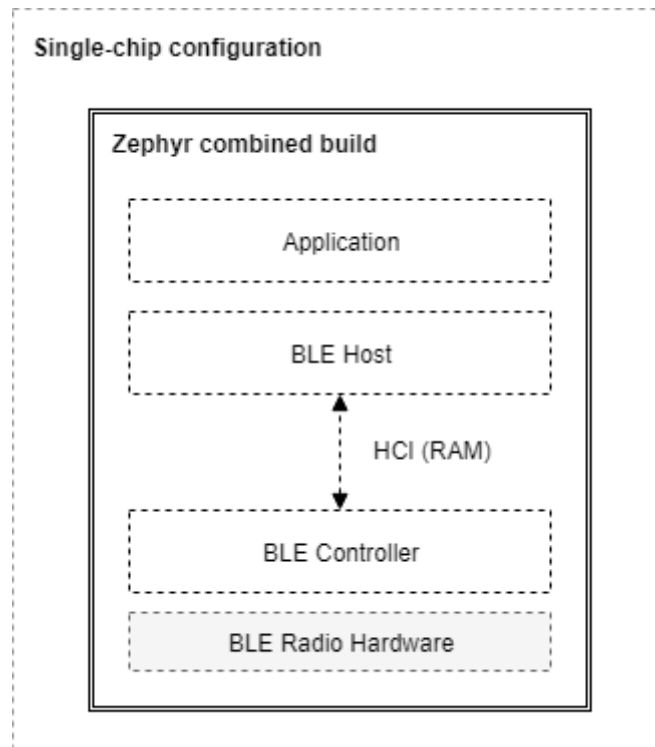

Fig. 1: A Combined build on a Single-Chip configuration

When using connectivity or dual-chip configurations, several Host and Controller combinations are possible, some of which are depicted below:

When using a Zephyr Host (left side of image), two instances of Zephyr OS must be built with different configurations, yielding two separate images that must be programmed into each of the chips respectively. The Host build image contains the application, the BLE Host and the selected HCI driver (UART or SPI), while the Controller build runs either the `hci_uart`, or the `hci_spi` app to provide an interface to the BLE Controller.

This configuration is not limited to using a Zephyr OS Host, as the right side of the image shows. One can indeed take one of the many existing GNU/Linux distributions, most of which include Linux's own BLE Host (BlueZ), to connect it via UART or USB to one or more instances of the Zephyr OS Controller build. BlueZ as a Host supports multiple Controllers simultaneously for applications that require more than one BLE radio operating at the same time but sharing the same Host stack.

### Source tree layout

The stack is split up as follows in the source tree:

`subsys/bluetooth/host` The host stack. This is where the HCI command and event handling as well as connection tracking happens. The implementation of the core protocols such as L2CAP, ATT, and SMP is also here.

`subsys/bluetooth/controller` Bluetooth Controller implementation. Implements the controller-side of HCI, the Link Layer as well as access to the radio transceiver.

`include/bluetooth/` Public API header files. These are the header files applications need to include in order to use Bluetooth functionality.

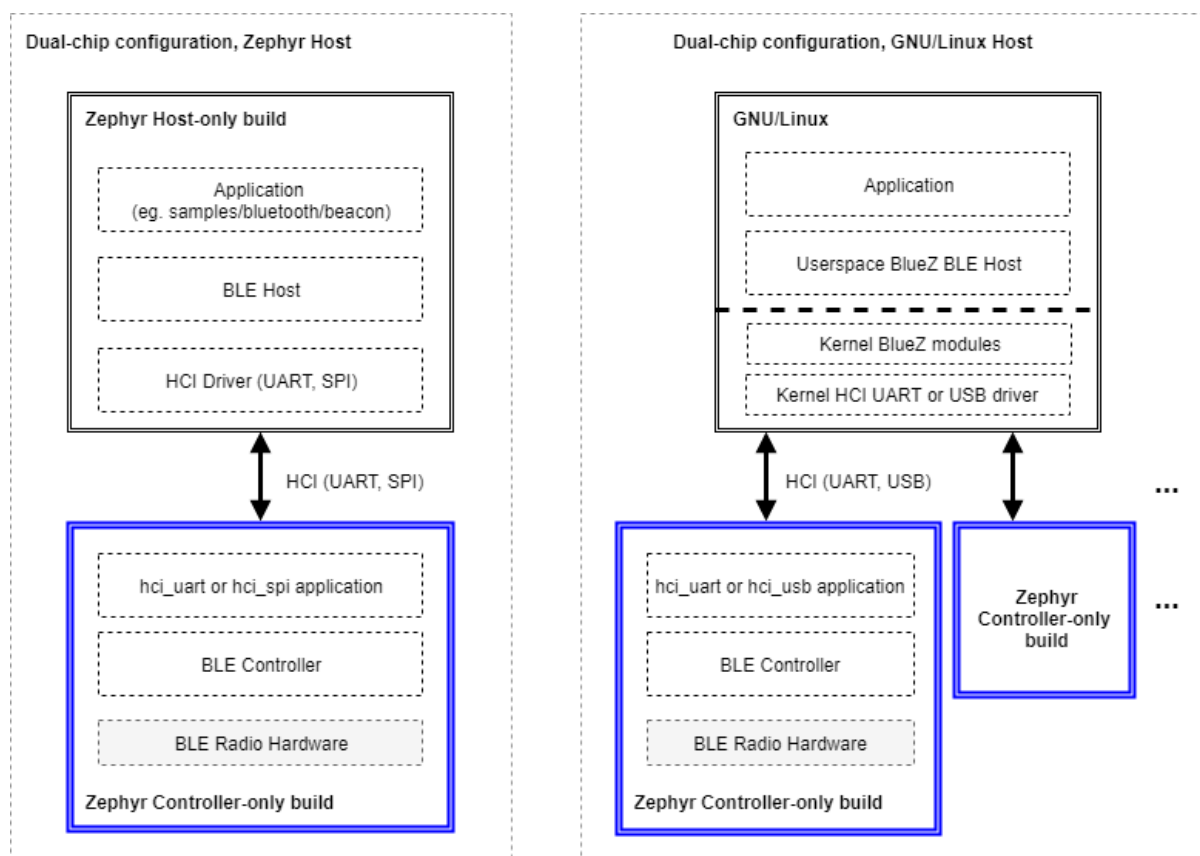

Fig. 2: Host-only and Controller-only builds on dual-chip configurations

`drivers/bluetooth/` HCI transport drivers. Every HCI transport needs its own driver. For example, the two common types of UART transport protocols (3-Wire and 5-Wire) have their own drivers.

`samples/bluetooth/` Sample Bluetooth code. This is a good reference to get started with Bluetooth application development.

`tests/bluetooth/` Test applications. These applications are used to verify the functionality of the Bluetooth stack, but are not necessary the best source for sample code (see `samples/bluetooth` instead).

`doc/guides/bluetooth/` Extra documentation, such as PICS documents.

## Host

The Bluetooth Host implements all the higher-level protocols and profiles, and most importantly, provides a high-level API for applications. The following diagram depicts the main protocol & profile layers of the host.

Lowest down in the host stack sits a so-called HCI driver, which is responsible for abstracting away the details of the HCI transport. It provides a basic API for delivering data from the controller to the host, and vice-versa.

Perhaps the most important block above the HCI handling is the Generic Access Profile (GAP). GAP simplifies Bluetooth LE access by defining four distinct roles of BLE usage:

- Connection-oriented roles
  - Peripheral (e.g. a smart sensor, often with a limited user interface)
  - Central (typically a mobile phone or a PC)

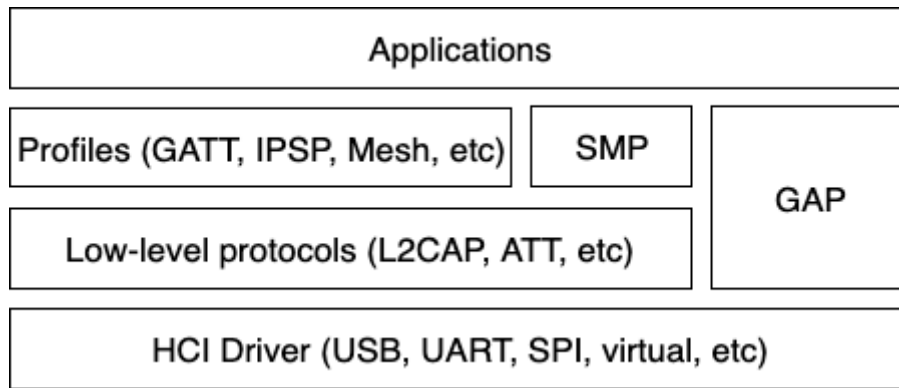

Fig. 3: Bluetooth Host protocol &amp; profile layers.

- Connection-less roles
  - Broadcaster (sending out BLE advertisements, e.g. a smart beacon)
  - Observer (scanning for BLE advertisements)

Each role comes with its own build-time configuration option: `:kconfig:CONFIG_BT_PERIPHERAL`, `:kconfig:CONFIG_BT_CENTRAL`, `:kconfig:CONFIG_BT_BROADCASTER` & `:kconfig:CONFIG_BT_OBSERVER`. Of the connection-oriented roles central implicitly enables observer role, and peripheral implicitly enables broadcaster role. Usually the first step when creating an application is to decide which roles are needed and go from there. Bluetooth mesh is a slightly special case, requiring at least the observer and broadcaster roles, and possibly also the Peripheral role. This will be described in more detail in a later section.

**Peripheral role** Most Zephyr-based BLE devices will most likely be peripheral-role devices. This means that they perform connectable advertising and expose one or more GATT services. After registering services using the `bt_gatt_service_register()` API the application will typically start connectable advertising using the `bt_le_adv_start()` API.

There are several peripheral sample applications available in the tree, such as `samples/bluetooth/peripheral_hr`.

**Central role** Central role may not be as common for Zephyr-based devices as peripheral role, but it is still a plausible one and equally well supported in Zephyr. Rather than accepting connections from other devices a central role device will scan for available peripheral device and choose one to connect to. Once connected, a central will typically act as a GATT client, first performing discovery of available services and then accessing one or more supported services.

To initially discover a device to connect to the application will likely use the `bt_le_scan_start()` API, wait for an appropriate device to be found (using the scan callback), stop scanning using `bt_le_scan_stop()` and then connect to the device using `bt_conn_create_le()`. If the central wants to keep automatically reconnecting to the peripheral it should use the `bt_le_set_auto_conn()` API.

There are some sample applications for the central role available in the tree, such as `samples/bluetooth/central_hr`.

**Observer role** An observer role device will use the `bt_le_scan_start()` API to scan for device, but it will not connect to any of them. Instead it will simply utilize the advertising data of found devices, combining it optionally with the received signal strength (RSSI).

**Broadcaster role** A broadcaster role device will use the `bt_le_adv_start()` API to advertise specific advertising data, but the type of advertising will be non-connectable, i.e. other device will not be able to connect to it.

**Connections** Connection handling and the related APIs can be found in the [Connection Management](#) section.

**Security** To achieve a secure relationship between two Bluetooth devices a process called pairing is used. This process can either be triggered implicitly through the security properties of GATT services, or explicitly using the `bt_conn_security()` API on a connection object.

To achieve a higher security level, and protect against Man-In-The-Middle (MITM) attacks, it is recommended to use some out-of-band channel during the pairing. If the devices have a sufficient user interface this “channel” is the user itself. The capabilities of the device are registered using the `bt_conn_auth_cb_register()` API. The `bt_conn_auth_cb` struct that’s passed to this API has a set of optional callbacks that can be used during the pairing - if the device lacks some feature the corresponding callback may be set to NULL. For example, if the device does not have an input method but does have a display, the `passkey_entry` and `passkey_confirm` callbacks would be set to NULL, but the `passkey_display` would be set to a callback capable of displaying a passkey to the user.

Depending on the local and remote security requirements & capabilities, there are four possible security levels that can be reached:

`BT_SECURITY_L1` No encryption and no authentication.

`BT_SECURITY_L2` Encryption but no authentication (no MITM protection).

`BT_SECURITY_L3` Encryption and authentication using the legacy pairing method from Bluetooth 4.0 and 4.1.

`BT_SECURITY_L4` Encryption and authentication using the LE Secure Connections feature available since Bluetooth 4.2.

---

**Note:** Mesh has its own security solution through a process called provisioning. It follows a similar procedure as pairing, but is done using separate mesh-specific APIs.

---

**L2CAP** L2CAP stands for the Logical Link Control and Adaptation Protocol. It is a common layer for all communication over Bluetooth connections, however an application comes in direct contact with it only when using it in the so-called Connection-oriented Channels (CoC) mode. More information on this can be found in the [L2CAP API section](#).

**GATT** The Generic Attribute Profile is the most common means of communication over LE connections. A more detailed description of this layer and the API reference can be found in the [GATT API reference section](#).

**Mesh** Mesh is a little bit special when it comes to the needed GAP roles. By default, mesh requires both observer and broadcaster role to be enabled. If the optional GATT Proxy feature is desired, then peripheral role should also be enabled.

The API reference for mesh can be found in the [Mesh API reference section](#).

**Persistent storage** The Bluetooth host stack uses the settings subsystem to implement persistent storage to flash. This requires the presence of a flash driver and a designated “storage” partition on flash. A typical set of configuration options needed will look something like the following:

```
CONFIG_BT_SETTINGS=y
CONFIG_FLASH=y
CONFIG_FLASH_PAGE_LAYOUT=y
CONFIG_FLASH_MAP=y
CONFIG_NVS=y
CONFIG_SETTINGS=y
```

Once enabled, it is the responsibility of the application to call `settings_load()` after having initialized Bluetooth (using the `bt_enable()` API).

## BLE Controller

### Standard

### Split

## 8.3.3 Bluetooth Qualification

### Qualification Listings

The Zephyr BLE stack has obtained qualification listings for both the Host and the Controller. See the tables below for a list of qualification listings

#### Host qualifications

Zephyr version	Link	Qualifying Company
2.2.x	<a href="#">QDID 151074</a>	Demant A/S
1.14.x	<a href="#">QDID 139258</a>	The Linux Foundation
1.13	<a href="#">QDID 119517</a>	Nordic Semiconductor

#### Mesh qualifications

Zephyr version	Link	Qualifying Company
1.14.x	<a href="#">QDID 139259</a>	The Linux Foundation

#### Controller qualifications

Zephyr version	Link	Qualifying Company	Compatible Hardware
2.2.x	<a href="#">QDID 150092</a>	Nordic Semiconductor	nRF52x
1.14.x	<a href="#">QDID 135679</a>	Nordic Semiconductor	nRF52x
1.9 to 1.13	<a href="#">QDID 101395</a>	Nordic Semiconductor	nRF52x

## ICS Features

The ICS features for each supported protocol & profile can be found in the following documents:

**GAP ICS** PTS version: 8.0.3

M - mandatory

O - optional

### Device Configuration

Parameter Name	Selected	Description
TSPC_GAP_0_1	False	BR/EDR (C.1)
TSPC_GAP_0_2	True	LE (C.2)
TSPC_GAP_0_3	False	BR/EDR/LE (C.3)

### Modes

Parameter Name	Selected	Description
TSPC_GAP_1_1	False	Non-discoverable mode (C.1)
TSPC_GAP_1_2	False	Limited-discoverable mode (O)
TSPC_GAP_1_3	False	General-discoverable mode (O)
TSPC_GAP_1_4	False	Non-connectable mode (O)
TSPC_GAP_1_5	False	Connectable mode (M)
TSPC_GAP_1_6	False	Non-bondable mode (O)
TSPC_GAP_1_7	False	Bondable mode (C.2)
TSPC_GAP_1_8	False	Non-Synchronizable Mode (C.3)
TSPC_GAP_1_9	False	Synchronizable Mode (C.4)

### Security Aspects

Parameter Name	Selected	Description
TSPC_GAP_2_1	False	Authentication procedure (C.1)
TSPC_GAP_2_2	False	Support of LMP-Authentication (M)
TSPC_GAP_2_3	False	Initiate LMP-Authentication (C.5)
TSPC_GAP_2_4	False	Security mode 1 (C.2)
TSPC_GAP_2_5	False	Security mode 2 (O)
TSPC_GAP_2_6	False	Security mode 3 (C.7)
TSPC_GAP_2_7	False	Security mode 4 (M)
TSPC_GAP_2_7a	False	Security mode 4, level 4 (C.9)
TSPC_GAP_2_7b	False	Security mode 4, level 3 (C.9)
TSPC_GAP_2_7c	False	Security mode 4, level 2 (C.9)
TSPC_GAP_2_7d	False	Security mode 4, level 1 (C.9)
TSPC_GAP_2_8	False	Support of Authenticated link key (C.6)
TSPC_GAP_2_9	False	Support of Unauthenticated link key (C.6)
TSPC_GAP_2_10	False	Security Optional (C.6)
TSPC_GAP_2_11	False	Secure Connections Only Mode (C.8)
TSPC_GAP_2_12	False	56-bit minimum encryption key size (C.10)
TSPC_GAP_2_13	False	128-bit encryption key size capable (C.11)

### Idle Mode Procedures

Parameter Name	Selected	Description
TSPC_GAP_3_1	False	Initiation of general inquiry (C.1)
TSPC_GAP_3_2	False	Initiation of limited inquiry (C.1)
TSPC_GAP_3_3	False	Initiation of name discovery (O)
TSPC_GAP_3_4	False	Initiation of device discovery (O)
TSPC_GAP_3_5	False	Initiation of general bonding (O)
TSPC_GAP_3_6	False	Initiation of dedicated bonding (O)

### Establishment Procedures

Parameter Name	Selected	Description
TSPC_GAP_4_1	False	Support link establishment as initiator (M)
TSPC_GAP_4_2	False	Support link establishment as acceptor (M)
TSPC_GAP_4_3	False	Support channel establishment as initiator (O)
TSPC_GAP_4_4	False	Support channel establishment as acceptor (M)
TSPC_GAP_4_5	False	Support connection establishment as initiator (O)
TSPC_GAP_4_6	False	Support connection establishment as acceptor (O)
TSPC_GAP_4_7	False	Support synchronization establishment as receiver (C.1)

### LE Roles

Parameter Name	Selected	Description
TSPC_GAP_5_1	True	Broadcaster (C.1)
TSPC_GAP_5_2	True	Observer (C.1)
TSPC_GAP_5_3	True	Peripheral (C.1)
TSPC_GAP_5_4	True	Central (C.1)

### Broadcaster Physical Layer

Parameter Name	Selected	Description
TSPC_GAP_6_1	True	Transmitter (M)
TSPC_GAP_6_2	True	Receiver (O)

### Broadcaster Link Layer States

Parameter Name	Selected	Description
TSPC_GAP_7_1	True	Standby (M)
TSPC_GAP_7_2	True	Advertising (M)
TSPC_GAP_7_3	False	Isochronous Broadcasting State (C.1)

### Broadcaster Link Layer Advertising Event Types

Parameter Name	Selected	Description
TSPC_GAP_8_1	True	Non-Connectable Undirected Event (M)
TSPC_GAP_8_2	True	Scannable Undirected Event (O)
TSPC_GAP_8_3	True	Non-Connectable and Non-Scannable Directed Event (C.1)
TSPC_GAP_8_4	True	Scannable Directed Event (C.1)

### Broadcaster Link Layer Advertising Data Types

Parameter Name	Selected	Description
TSPC_GAP_8a_1	True	AD Type – Service UUID (O)
TSPC_GAP_8a_2	True	AD Type – Local Name (O)
TSPC_GAP_8a_3	True	AD Type – Flags (O)
TSPC_GAP_8a_4	True	AD Type – Manufacturer Specific Data (O)
TSPC_GAP_8a_5	True	AD Type – TX Power Level (O)
TSPC_GAP_8a_6	False	AD Type – Security Manager Out of Band (OOB) (C.1)
TSPC_GAP_8a_7	True	AD Type – Security Manager TK Value (O)
TSPC_GAP_8a_8	True	AD Type – Peripheral Connection Interval Range (O)
TSPC_GAP_8a_9	True	AD Type - Service Solicitation (O)
TSPC_GAP_8a_10	True	AD Type – Service Data (O)
TSPC_GAP_8a_11	True	AD Type – Appearance (O)
TSPC_GAP_8a_12	True	AD Type – Public Target Address (O)
TSPC_GAP_8a_13	True	AD Type – Random Target Address (O)
TSPC_GAP_8a_14	True	AD Type – Advertising Interval (O)
TSPC_GAP_8a_15	True	AD Type – LE Bluetooth Device Address (O)
TSPC_GAP_8a_16	True	AD Type – LE Role (O)
TSPC_GAP_8a_17	True	AD Type - URI (O)

#### Broadcaster Connection Modes and Procedures

Parameter Name	Selected	Description
TSPC_GAP_9_1	True	Non-Connectable Mode (M)

#### Broadcaster Broadcasting and Observing Features

Parameter Name	Selected	Description
TSPC_GAP_10_1	True	Broadcast Mode (M)
TSPC_GAP_10_2	False	Broadcast Isochronous Synchronizability mode (C.1)
TSPC_GAP_10_3	False	Broadcast Isochronous Broadcasting mode (C.2)
TSPC_GAP_10_4	False	Broadcast Isochronous Terminate procedure (C.1)
TSPC_GAP_10_5	False	Broadcast Isochronous Channel Map Update Procedure (C.1)

#### Broadcaster Privacy Feature

Parameter Name	Selected	Description
TSPC_GAP_11_1	True	Privacy Feature (O)
TSPC_GAP_11_2	True	Resolvable Private Address Generation Procedure (C.1)
TSPC_GAP_11_3	True	Non-Resolvable Private Address Generation Procedure (C.2)

#### Periodic Advertising Modes and Procedures

Parameter Name	Selected	Description
TSPC_GAP_11a_1	False	Periodic Advertising Synchronizability mode (C.1)
TSPC_GAP_11a_2	False	Periodic Advertising mode (C.2)

#### Broadcaster Security Aspects Features

Parameter Name	Selected	Description
TSPC_GAP_11b_1	False	LE Security Mode 3 (C.1)
TSPC_GAP_11b_2	False	LE Security Mode 3, Level 1 (C.2)
TSPC_GAP_11b_3	False	LE Security Mode 3, Level 2 (C.2)
TSPC_GAP_11b_4	False	LE Security Mode 3, Level 3 (C.2)

**Observer Physical Layer**

Parameter Name	Selected	Description
TSPC_GAP_12_1	True	Receiver (M)
TSPC_GAP_12_2	True	Transmitter (O)

**Observer Link Layer States**

Parameter Name	Selected	Description
TSPC_GAP_13_1	True	Standby (M)
TSPC_GAP_13_2	True	Scanning (M)

**Observer Link Layer Scanning Types**

Parameter Name	Selected	Description
TSPC_GAP_14_1	True	Passive Scanning (M)
TSPC_GAP_14_2	True	Active Scanning (O)

**Observer Connection Modes and Procedures**

Parameter Name	Selected	Description
TSPC_GAP_15_1	True	Non-Connectable Modes (M)

**Observer Broadcasting and Observing Features**

Parameter Name	Se- lected	Description
TSPC_GAP_16_1	True	Observation Procedure (M)
TSPC_GAP_16_2	False	Broadcast Isochronous Synchronization Establishment procedure (C.1)
TSPC_GAP_16_3	False	Broadcast Isochronous Termination procedure (C.2)
TSPC_GAP_16_4	False	Broadcast Isochronous Channel Map Update Procedure (C.2)

**Observer Privacy Feature**

Parameter Name	Selected	Description
TSPC_GAP_17_1	True	Privacy Feature (O)
TSPC_GAP_17_2	True	Non-Resolvable Private Address Generation Procedure (C.1)
TSPC_GAP_17_3	True	Resolvable Private Address Resolution Procedure (O)
TSPC_GAP_17_4	True	Resolvable Private Address Generation Procedure (C.2)

**Periodic Advertising Modes and Procedures**

Parameter Name	Se- lected	Description
TSPC_GAP_17_1	False	Periodic Advertising Synchronization Establishment procedure without listening for periodic advertising (C.1)
TSPC_GAP_17_2	False	Periodic Advertising Synchronization Establishment procedure with listening for periodic advertising (C.1)

**Observer Security Aspects Features**

Parameter Name	Selected	Description
TSPC_GAP_17b_1	False	LE Security Mode 3 (C.1)
TSPC_GAP_17b_2	False	LE Security Mode 3, Level 1 (C.2)
TSPC_GAP_17b_3	False	LE Security Mode 3, Level 2 (C.2)
TSPC_GAP_17b_4	False	LE Security Mode 3, Level 3 (C.2)

### Peripheral Physical Layer

Parameter Name	Selected	Description
TSPC_GAP_18_1	True	Transmitter (M)
TSPC_GAP_18_2	True	Receiver (M)

### Peripheral Link Layer States

Parameter Name	Selected	Description
TSPC_GAP_19_1	True	Standby (M)
TSPC_GAP_19_2	True	Advertising (M)
TSPC_GAP_19_3	True	Connection, Peripheral Role (M)

### Peripheral Link Layer Advertising Event Types

Parameter Name	Selected	Description
TSPC_GAP_20_1	True	Connectable and Scannable Undirected Event (M)
TSPC_GAP_20_2	True	Connectable Directed Event (O)
TSPC_GAP_20_3	True	Non-Connectable and Non-Scannable Undirected Event (O)
TSPC_GAP_20_4	True	Scannable Undirected Event (O)
TSPC_GAP_20_5	True	Connectable Undirected Event (C.1)
TSPC_GAP_20_6	True	Non-Connectable and Non-Scannable Directed Event (C.1)
TSPC_GAP_20_7	True	Scannable Directed Event (C.1)

### Peripheral Link Layer Advertising Data Types

Parameter Name	Selected	Description
TSPC_GAP_20A_1	True	AD Type – Service UUID (C.1)
TSPC_GAP_20A_2	True	AD Type – Local Name (C.1)
TSPC_GAP_20A_3	True	AD Type – Flags (C.2)
TSPC_GAP_20A_4	True	AD Type – Manufacturer Specific Data (C.1)
TSPC_GAP_20A_5	True	AD Type – TX Power Level (C.1)
TSPC_GAP_20A_6	False	AD Type – Security Manager Out of Band (OOB) (C.3)
TSPC_GAP_20A_7	True	AD Type – Security Manager TK Value (C.1)
TSPC_GAP_20A_8	True	AD Type – Peripheral Connection Interval Range (C.1)
TSPC_GAP_20A_9	True	AD Type – Service Solicitation (C.1)
TSPC_GAP_20A_10	True	AD Type – Service Data (C.1)
TSPC_GAP_20A_11	True	AD Type – Appearance (C.1)
TSPC_GAP_20A_12	True	AD Type – Public Target Address (C.1)
TSPC_GAP_20A_13	True	AD Type – Random Target Address (C.1)
TSPC_GAP_20A_14	True	AD Type – Advertising Interval (C.1)
TSPC_GAP_20A_15	True	AD Type – LE Bluetooth Device Address (C.1)
TSPC_GAP_20A_16	True	AD Type – LE Role (C.1)
TSPC_GAP_20A_17	True	AD Type – URI (O)

### Peripheral Link Layer Control Procedures

Parameter Name	Selected	Description
TSPC_GAP_21_1	True	Connection Update Procedure (M)
TSPC_GAP_21_2	True	Channel Map Update Procedure (M)
TSPC_GAP_21_3	True	Encryption Procedure (O)
TSPC_GAP_21_4	True	Central Initiated Feature Exchange Procedure (M)
TSPC_GAP_21_5	True	Version Exchange Procedure (M)
TSPC_GAP_21_6	True	Termination Procedure (M)
TSPC_GAP_21_7	True	LE Ping Procedure (O)
TSPC_GAP_21_8	True	Peripheral Initiated Feature Exchange Procedure (C.1)
TSPC_GAP_21_9	True	Connection Parameter Request Procedure (O)
TSPC_GAP_21_10	True	Data Length Update Procedure (O)
TSPC_GAP_21_11	True	PHY Update Procedure (C.2)
TSPC_GAP_21_12	False	Minimum Number Of Used Channels Procedure (C.2)

### Peripheral Discovery Modes and Procedures

Parameter Name	Selected	Description
TSPC_GAP_22_1	True	Non-Discoverable Mode (M)
TSPC_GAP_22_2	True	Limited Discoverable Mode (O)
TSPC_GAP_22_3	True	General Discoverable Mode (C.1)
TSPC_GAP_22_4	True	Name Discovery Procedure (O)

### Peripheral Connection Modes and Procedures

Parameter Name	Selected	Description
TSPC_GAP_23_1	True	Non-Connectable Mode (M)
TSPC_GAP_23_2	False	Directed Connectable Mode (O)
TSPC_GAP_23_3	True	Undirected Connectable Mode (M)
TSPC_GAP_23_4	True	Connection Parameter Update Procedure (O)
TSPC_GAP_23_5	True	Terminate Connection Procedure (M)
TSPC_GAP_23_6	False	Connected Isochronous Stream Request procedure (C.1)
TSPC_GAP_23_7	False	Connected Isochronous Stream Termination procedure (C.1)

### Peripheral Bonding Modes and Procedures

Parameter Name	Selected	Description
TSPC_GAP_24_1	True	Non-Bondable Mode (M)
TSPC_GAP_24_2	True	Bondable Mode (O)
TSPC_GAP_24_3	True	Bonding Procedure (O)
TSPC_GAP_24_4	True	Multiple Bonds (C.1)

### Peripheral Security Aspects Features

Parameter Name	Selected	Description
TSPC_GAP_25_1	True	Security Mode 1 (O)
TSPC_GAP_25_2	True	Security Mode 2 (O)
TSPC_GAP_25_3	True	Authentication Procedure (O)
TSPC_GAP_25_4	True	Authorization Procedure (O)
TSPC_GAP_25_5	True	Connection Data Signing Procedure (O)
TSPC_GAP_25_6	True	Authenticate Signed Data Procedure (O)
TSPC_GAP_25_7	True	Authenticated Pairing (LE security mode 1 level 3) (C.1)
TSPC_GAP_25_8	True	Unauthenticated Pairing (LE security mode 1 level 2) (C.1)
TSPC_GAP_25_9	True	LE Security Mode 1 Level 4 (C.3)
TSPC_GAP_25_10	True	Secure Connections Only Mode (C.4)
TSPC_GAP_25_11	False	Unauthenticated Pairing (LE security mode 1 level 2) with LE Secure Connections Pairing only (C.3)
TSPC_GAP_25_12	False	Authenticated Pairing (LE security mode 1 level 3) with LE Secure Connections Pairing only (C.3)
TSPC_GAP_25_13	True	Minimum 128 Bit entropy key (C.5)

### Peripheral Privacy Feature

Parameter Name	Selected	Description
TSPC_GAP_26_1	True	Privacy Feature (O)
TSPC_GAP_26_2	True	Non-Resolvable Private Address Generation Procedure (O)
TSPC_GAP_26_3	True	Resolvable Private Address Generation Procedure (C.1)
TSPC_GAP_26_4	True	Resolvable Private Address Resolution Procedure (C.1)

### Peripheral GAP Characteristics

Parameter Name	Selected	Description
TSPC_GAP_27_1	True	Device Name (M)
TSPC_GAP_27_2	True	Appearance (M)
TSPC_GAP_27_5	True	Peripheral Preferred Connection Parameters (O)
TSPC_GAP_27_6	True	Writeable Device Name (O)
TSPC_GAP_27_7	False	Writeable Appearance (O)
TSPC_GAP_27_9	True	Central Address Resolution (C.1)

### Periodic Advertising Modes and Procedures

Parameter Name	Selected	Description
TSPC_GAP_27_12	False	Periodic Advertising Synchronization Transfer procedure (C.1)
TSPC_GAP_27_13	False	Periodic Advertising Synchronization Establishment procedure over an LE connection without listening for periodic advertising (C.2)
TSPC_GAP_27_14	False	Periodic Advertising Synchronization Establishment procedure over an LE connection with listening for periodic advertising (C.3)

### Central Physical Layer

Parameter Name	Selected	Description
TSPC_GAP_28_1	True	Transmitter (M)
TSPC_GAP_28_2	True	Receiver (M)

**Central Link Layer States**

Parameter Name	Selected	Description
TSPC_GAP_29_1	True	Standby (M)
TSPC_GAP_29_2	True	Scanning (M)
TSPC_GAP_29_3	True	Initiating (M)
TSPC_GAP_29_4	True	Connection, Central Role (M)

**Central Link Layer Scanning Types**

Parameter Name	Selected	Description
TSPC_GAP_30_1	True	Passive Scanning (O)
TSPC_GAP_30_2	True	Active Scanning (C.1)

**Central Link Layer Control Procedures**

Parameter Name	Selected	Description
TSPC_GAP_31_1	True	Connection Update Procedure (M)
TSPC_GAP_31_2	True	Channel Map Update Procedure (M)
TSPC_GAP_31_3	True	Encryption Procedure (O)
TSPC_GAP_31_4	True	Central Initiated Feature Exchange Procedure (M)
TSPC_GAP_31_5	True	Version Exchange Procedure (M)
TSPC_GAP_31_6	True	Termination Procedure (M)
TSPC_GAP_31_7	False	LE Ping Procedure (O)
TSPC_GAP_31_8	True	Peripheral Initiated Feature Exchange Procedure (C.1)
TSPC_GAP_31_9	True	Connection Parameter Request Procedure (O)
TSPC_GAP_31_10	True	Data Length Update Procedure (O)
TSPC_GAP_31_11	True	PHY Update Procedure (C.2)
TSPC_GAP_31_12	False	Minimum Number Of Used Channels Procedure (C.2)

**Central Discovery Modes and Procedures**

Parameter Name	Selected	Description
TSPC_GAP_32_1	True	Limited Discovery Procedure (O)
TSPC_GAP_32_2	True	General Discovery Procedure (M)
TSPC_GAP_32_3	True	Name Discovery Procedure (O)

**Central Connection Modes and Procedures**

Parameter Name	Selected	Description
TSPC_GAP_33_1	True	Auto Connection Establishment Procedure (O)
TSPC_GAP_33_2	True	General Connection Establishment Procedure (O)
TSPC_GAP_33_3	False	Selective Connection Establishment Procedure (O)
TSPC_GAP_33_4	True	Selective Connection Establishment Procedure (M)
TSPC_GAP_33_5	True	Connection Parameter Update Procedure (M)
TSPC_GAP_33_6	True	Terminate Connection Procedure (M)
TSPC_GAP_33_7	False	Connected Isochronous Stream Creation procedure (C.1)
TSPC_GAP_33_8	False	Connected Isochronous Stream Termination procedure (C.1)

**Central Bonding Modes and Procedures**

Parameter Name	Selected	Description
TSPC_GAP_34_1	True	Non-Bondable Mode (M)
TSPC_GAP_34_2	True	Bondable Mode (O)
TSPC_GAP_34_3	True	Bonding Procedure (O)

### Central Security Features

Parameter Name	Selected	Description
TSPC_GAP_35_1	True	Security Mode 1 (O)
TSPC_GAP_35_2	True	Security Mode 2 (O)
TSPC_GAP_35_3	True	Authentication Procedure (O)
TSPC_GAP_35_4	False	Authorization Procedure (O)
TSPC_GAP_35_5	True	Connection Data Signing Procedure (O)
TSPC_GAP_35_6	True	Authenticate Signed Data Procedure (O)
TSPC_GAP_35_7	True	Authenticated Pairing (LE security mode 1 level 3) (C.1)
TSPC_GAP_35_8	True	Unauthenticated Pairing (LE security mode 1 level 2) (C.1)
TSPC_GAP_35_9	True	LE Security Mode 1 Level 4 (C.2)
TSPC_GAP_35_10	True	Secure Connections Only Mode (C.3)
TSPC_GAP_35_11	False	Unauthenticated Pairing (LE security mode 1 level 2) with LE Secure Connections Pairing only (C.2)
TSPC_GAP_35_12	False	Authenticated Pairing (LE security mode 1 level 3) with LE Secure Connections Pairing only (C.2)
TSPC_GAP_35_13	True	Minimum 128 Bit entropy key (C.4)

### Central Privacy Feature

Parameter Name	Selected	Description
TSPC_GAP_36_1	True	Privacy Feature (O)
TSPC_GAP_36_2	True	Non-Resolvable Private Address Generation Procedure (O)
TSPC_GAP_36_3	True	Resolvable Private Address Resolution Procedure (C.1)
TSPC_GAP_36_5	True	Resolvable Private Address Generation Procedure (C.1)

### Central GAP Characteristics

Parameter Name	Selected	Description
TSPC_GAP_37_1	True	Device Name (M)
TSPC_GAP_37_2	True	Appearance (M)
TSPC_GAP_37_3	True	Central Address Resolution (C.1)

### Periodic Advertising Modes and Procedures

Parameter Name	Selected	Description
TSPC_GAP_37_4	False	Periodic Advertising Synchronization Transfer procedure (C.1)
TSPC_GAP_37_5	False	Periodic Advertising Synchronization Establishment procedure over an LE connection without listening for periodic advertising (C.2)
TSPC_GAP_37_6	False	Periodic Advertising Synchronization Establishment procedure over an LE connection with listening for periodic advertising (C.3)

### BR/EDR/LE Roles

Parameter Name	Selected	Description
TSPC_GAP_38_1	False	Broadcaster (C.1)
TSPC_GAP_38_2	False	Observer (C.1)
TSPC_GAP_38_3	False	Peripheral (C.1)
TSPC_GAP_38_4	False	Central (C.1)

### Central BR/EDR/LE Security Aspects

Parameter Name	Selected	Description
TSPC_GAP_41_1	False	Security Aspects (M)
TSPC_GAP_41_2a	False	Derivation of BR/EDR Link Key from LE LTK (C.1)
TSPC_GAP_41_2b	False	Derivation of LE LTK from BR/EDR Link Key (C.2)

#### Peripheral BR/EDR/LE Security Aspects

Parameter Name	Selected	Description
TSPC_GAP_43_1	False	Security Aspects (M)
TSPC_GAP_43_2a	False	Derivation of BR/EDR Link Key from LE LTK (C.1)
TSPC_GAP_43_2b	False	Derivation of LE LTK from BR/EDR Link Key (C.2)

#### Central Simultaneous BR/EDR and LE Transports

Parameter Name	Selected	Description
TSPC_GAP_44_1	False	Simultaneous BR/EDR and LE Transports – BR/EDR Peripheral to the same device (O)
TSPC_GAP_44_2	False	Simultaneous BR/EDR and LE Transports – BR/EDR Central to the same device (O)

#### Peripheral Simultaneous BR/EDR and LE Transports

Parameter Name	Selected	Description
TSPC_GAP_45_1	False	Simultaneous BR/EDR and LE Transports – BR/EDR Peripheral to the same device (O)
TSPC_GAP_45_2	False	Simultaneous BR/EDR and LE Transports – BR/EDR Central to the same device (O)

**GATT ICS** PTS version: 8.0.3

M - mandatory

O - optional

#### Generic Attribute Profile Support

Parameter Name	Selected	Description
TSPC_GATT_1_1	True	Generic Attribute Profile (GATT) Client (C.1)
TSPC_GATT_1_2	True	Generic Attribute Profile (GATT) Server (C.2)

#### GATT role configuration

Parameter Name	Selected	Description
TSPC_GATT_1a_1	True	GATT Client over LE (C.1)
TSPC_GATT_1a_2	False	GATT Client over BR/EDR (C.2)
TSPC_GATT_1a_3	True	GATT Server over LE (C.3)
TSPC_GATT_1a_4	False	GATT Server over BR/EDR (C.4)

## Attribute Protocol Transport

Parameter Name	Selected	Description
TSPC_GATT_2_1	False	Attribute Protocol Supported over BR/EDR (L2CAP fixed channel support) (C.1)
TSPC_GATT_2_2	True	Attribute Protocol Supported over LE (C.2)
TSPC_GATT_2_3	True	Enhanced ATT bearer Attribute Protocol Supported (L2CAP fixed EATT PSM supported) (C.3)
TSPC_GATT_2_3a	True	Enhanced ATT bearer supported over LE (C.4)
TSPC_GATT_2_3b	False	Enhanced ATT bearer supported over BR/EDR (C.5)

## Generic Attribute Profile Feature Support, by Client

Parameter Name	Selected	Description
TSPC_GATT_3_1	True	Exchange MTU (C.11)
TSPC_GATT_3_2	True	Discover All Primary Services (O)
TSPC_GATT_3_3	True	Discover Primary Services by Service UUID (O)
TSPC_GATT_3_4	True	Find Included Services (O)
TSPC_GATT_3_5	True	Discover All characteristics of a Service (O)
TSPC_GATT_3_6	True	Discover Characteristics by UUID (O)
TSPC_GATT_3_7	True	Discover All Characteristic Descriptors (O)
TSPC_GATT_3_8	True	Read Characteristic Value (O)
TSPC_GATT_3_9	True	Read Using Characteristic UUID (O)
TSPC_GATT_3_10	True	Read Long Characteristic Values (O)
TSPC_GATT_3_11	True	Read Multiple Characteristic Values (O)
TSPC_GATT_3_12	True	Write without Response (O)
TSPC_GATT_3_13	True	Signed Write Without Response (C.11)
TSPC_GATT_3_14	True	Write Characteristic Value (O)
TSPC_GATT_3_15	True	Write Long Characteristic Values (O)
TSPC_GATT_3_16	True	Characteristic Value Reliable Writes (O)
TSPC_GATT_3_17	True	Notifications (C.7)
TSPC_GATT_3_18	True	Indications (M)
TSPC_GATT_3_19	True	Read Characteristic Descriptors (O)
TSPC_GATT_3_20	True	Read Long Characteristic Descriptors (O)
TSPC_GATT_3_21	True	Write Characteristic Descriptors (O)
TSPC_GATT_3_22	True	Write Long Characteristic Descriptors (O)
TSPC_GATT_3_23	True	Service Changed Characteristic (M)
TSPC_GATT_3_24	False	Configured Broadcast (C.2)
TSPC_GATT_3_25	True	Client Supported Features Characteristic (C.4)
TSPC_GATT_3_26	True	Database Hash Characteristic (C.4)
TSPC_GATT_3_27	False	Read and Interpret Characteristic Presentation Format (O)
TSPC_GATT_3_28	False	Read and Interpret Characteristic Aggregate Format (C.6)
TSPC_GATT_3_29	False	Read Multiple Variable Length Characteristic Values (C.9)
TSPC_GATT_3_30	False	Multiple Variable Length Notifications (C.10)

## Generic Attribute Profile Feature Support, by Server

Parameter Name	Selected	Description
TSPC_GATT_4_1	True	Exchange MTU (C.6)
TSPC_GATT_4_2	True	Discover All Primary Services (M)
TSPC_GATT_4_3	True	Discover Primary Services by Service UUID (M)
TSPC_GATT_4_4	True	Find Included Services (M)

continues on next page

Table 2 – continued from previous page

Parameter Name	Selected	Description
TSPC_GATT_4_5	True	Discover All characteristics of a Service (M)
TSPC_GATT_4_6	True	Discover Characteristics by UUID (M)
TSPC_GATT_4_7	True	Discover All Characteristic Descriptors (M)
TSPC_GATT_4_8	True	Read Characteristic Value (M)
TSPC_GATT_4_9	True	Read Using Characteristic UUID (M)
TSPC_GATT_4_10	True	Read Long Characteristic Values (C.12)
TSPC_GATT_4_11	True	Read Multiple Characteristic Values (O)
TSPC_GATT_4_12	True	Write without Response (C.2)
TSPC_GATT_4_13	True	Signed Write Without Response (C.6)
TSPC_GATT_4_14	True	Write Characteristic Value (C.3)
TSPC_GATT_4_15	True	Write Long Characteristic Values (C.12)
TSPC_GATT_4_16	True	Characteristic Value ReliableWrites (O)
TSPC_GATT_4_17	True	Notifications (O)
TSPC_GATT_4_18	True	Indications (C.1)
TSPC_GATT_4_19	True	Read Characteristic Descriptors (C.12)
TSPC_GATT_4_20	True	Read Long Characteristic Descriptors (C.12)
TSPC_GATT_4_21	True	Write Characteristic Descriptors (C.12)
TSPC_GATT_4_22	True	Write Long Characteristic Descriptors (O)
TSPC_GATT_4_23	True	Service Changed Characteristic (C.1)
TSPC_GATT_4_24	False	Configured Broadcast (C.5)
TSPC_GATT_4_25	False	Execute Write Request with empty queue (C.7)
TSPC_GATT_4_26	True	Client Supported Features Characteristic (C.9)
TSPC_GATT_4_27	True	Database Hash Characteristic (C.8)
TSPC_GATT_4_28	False	Report Characteristic Value: Characteristic Presentation Format (O)
TSPC_GATT_4_29	False	Report aggregate Characteristic Value: Characteristic Aggregate Format (C.10)
TSPC_GATT_4_30	False	Read Multiple Variable Length Characteristic Values (C.13)
TSPC_GATT_4_31	False	Multiple Variable Length Notifications (C.13)

### SDP Interoperability

Parameter Name	Selected	Description
TSPC_GATT_6_2	False	Discover GATT Services using Service Discovery Profile (C.1)
TSPC_GATT_6_3	False	Publish SDP record for GATT services support via BR/EDR (C.2)

### Attribute Protocol Transport Security

Parameter Name	Selected	Description
TSPC_GATT_7_1	False	Security Mode 4 (C.1)
TSPC_GATT_7_2	True	LE Security Mode 1 (C.5)
TSPC_GATT_7_3	True	LE Security Mode 2 (C.6)
TSPC_GATT_7_4	True	LE Authentication Procedure (C.4)
TSPC_GATT_7_5	True	LE connection data signing procedure (C.2)
TSPC_GATT_7_6	True	LE Authenticate signed data procedure (C.2)
TSPC_GATT_7_7	True	LE Authorization Procedure (C.3)

### Multiple Simultaneous ATT Bearers

Parameter Name	Selected	Description
TSPC_GATT_0_1	False	Support for multiple simultaneous active ATT bearers from same device – ATT over LE and ATT over BR/EDR (C.1)
TSPC_GATT_0_2	True	Support for multiple simultaneous active ATT bearers from same device – ATT over LE and EATT over LE (C.2)
TSPC_GATT_0_3	False	Support for multiple simultaneous active ATT bearers from same device – ATT over BR/EDR and EATT over BR/EDR (C.3)
TSPC_GATT_0_4	False	Support for multiple simultaneous active ATT bearers from same device – ATT over LE and EATT over BR/EDR (C.4)
TSPC_GATT_0_5	False	Support for multiple simultaneous active ATT bearers from same device – ATT over BR/EDR and EATT over LE (C.5)
TSPC_GATT_0_6	False	Support for multiple simultaneous active EATT bearers from same device – EATT over BR/EDR and EATT over LE (C.6)
TSPC_GATT_0_7	False	Support for multiple simultaneous active EATT bearers from same device – EATT over BR/EDR (C.7)
TSPC_GATT_0_8	True	Support for multiple simultaneous active EATT bearers from same device – EATT over LE (C.7)

## L2CAP ICS PTS version: 8.0.3

M - mandatory

O - optional

### L2CAP Transport Configuration

Parameter Name	Selected	Description
TSPC_L2CAP_0_1	False	BR/EDR (includes possible support of GAP LE Broadcaster or LE Observer roles) (C.1)
TSPC_L2CAP_0_2	True	LE (C.2)
TSPC_L2CAP_0_3	False	BR/EDR/LE (C.3)

### Roles

Parameter Name	Selected	Description
TSPC_L2CAP_1_1	False	Data Channel Initiator (C.3)
TSPC_L2CAP_1_2	False	Data Channel Acceptor (C.1)
TSPC_L2CAP_1_3	True	LE Master (C.2)
TSPC_L2CAP_1_4	True	LE Slave (C.2)
TSPC_L2CAP_1_5	True	LE Data Channel Initiator (C.4)
TSPC_L2CAP_1_6	True	LE Data Channel Acceptor (C.5)

### General Operation

Parameter Name	Selected	Description
TSPC_L2CAP_2_1	False	Support of L2CAP signalling channel (C.16)
TSPC_L2CAP_2_2	False	Support of configuration process (C.16)
TSPC_L2CAP_2_3	False	Support of connection oriented data channel (C.16)
TSPC_L2CAP_2_4	False	Support of command echo request (C.17)
TSPC_L2CAP_2_5	False	Support of command echo response (C.16)
TSPC_L2CAP_2_6	False	Support of command information request (C.17)

continues on

Table 3 – continued from previous page

Parameter Name	Selected	Description
TSPC_L2CAP_2_7	False	Support of command information response (C.16)
TSPC_L2CAP_2_8	False	Support of a channel group (C.17)
TSPC_L2CAP_2_9	False	Support of packet for connectionless channel (C.17)
TSPC_L2CAP_2_10	False	Support retransmission mode (C.17)
TSPC_L2CAP_2_11	False	Support flow control mode (C.17)
TSPC_L2CAP_2_12	False	Enhanced Retransmission Mode (C.11)
TSPC_L2CAP_2_13	False	Streaming Mode (O)
TSPC_L2CAP_2_14	False	FCS Option (C.1)
TSPC_L2CAP_2_15	False	Generate Local Busy Condition (C.2)
TSPC_L2CAP_2_16	False	Send Reject (C.2)
TSPC_L2CAP_2_17	False	Send Selective Reject (C.2)
TSPC_L2CAP_2_18	False	Mandatory use of ERTM (C.3)
TSPC_L2CAP_2_19	False	Mandatory use of Streaming Mode (C.4)
TSPC_L2CAP_2_20	False	Optional use of ERTM (C.3)
TSPC_L2CAP_2_21	False	Optional use of Streaming Mode (C.4)
TSPC_L2CAP_2_22	False	Send data using SAR in ERTM (C.5)
TSPC_L2CAP_2_23	False	Send data using SAR in Streaming Mode (C.6)
TSPC_L2CAP_2_24	False	Actively request Basic Mode for a PSM that supports the use of ERTM or Streaming Mode (C.10)
TSPC_L2CAP_2_25	False	Supports performing L2CAP channel mode configuration fallback from SM to ERTM (C.10)
TSPC_L2CAP_2_26	False	Supports sending more than one unacknowledged I-Frame when operating in ERTM (C.10)
TSPC_L2CAP_2_27	False	Supports sending more than three unacknowledged I-Frame when operating in ERTM (C.10)
TSPC_L2CAP_2_28	False	Supports configuring the peer TxWindow greater than 1. (C.10)
TSPC_L2CAP_2_29	False	AMP Support (C.11)
TSPC_L2CAP_2_30	False	Fixed Channel Support (C.11)
TSPC_L2CAP_2_31	False	AMP Manager Support (C.11)
TSPC_L2CAP_2_32	False	ERTM over AMP (C.11)
TSPC_L2CAP_2_33	False	Streaming Mode Source over AMP Support (C.12)
TSPC_L2CAP_2_34	False	Streaming Mode Sink over AMP Support (C.12)
TSPC_L2CAP_2_35	False	Unicast Connectionless Data, Reception (O)
TSPC_L2CAP_2_36	False	Ability to transmit an unencrypted packet over a unicast connectionless L2CAP channel (C.13)
TSPC_L2CAP_2_37	False	Ability to transmit an encrypted packet over a unicast connectionless L2CAP channel (C.13)
TSPC_L2CAP_2_38	False	Extended Flow Specification for BR/EDR (C.7)
TSPC_L2CAP_2_39	False	Extended Window Size (C.7)
TSPC_L2CAP_2_40	True	Support of Low Energy signaling channel (C.13)
TSPC_L2CAP_2_41	True	Support of command reject (C.13)
TSPC_L2CAP_2_42	True	Send Connection Parameter Update Request (C.14)
TSPC_L2CAP_2_43	True	Send Connection Parameter Update Response (C.15)
TSPC_L2CAP_2_44	False	Extended Flow Specification for AMP (C.18)
TSPC_L2CAP_2_45	False	Send Disconnect Request Command (C.21)
TSPC_L2CAP_2_45a	True	Send Disconnect Request Command – LE (C.22)
TSPC_L2CAP_2_46	True	Support LE Credit Based Flow Control Mode (C.19)
TSPC_L2CAP_2_47	True	Support for LE Data Channel (C.20)
TSPC_L2CAP_2_48	True	Support Enhanced Credit Based Flow Control Mode (C.23)

### Configurable Parameters

Parameter Name	Selected	Description
TSPC_L2CAP_3_1	True	Support of RTX timer (M)
TSPC_L2CAP_3_2	False	Support of ERTX timer (C.4)
TSPC_L2CAP_3_3	False	Support minimum MTU size 48 octets (C.4)
TSPC_L2CAP_3_4	False	Support MTU size larger than 48 octets (C.5)
TSPC_L2CAP_3_5	False	Support of flush timeout value for reliable channel (C.4)
TSPC_L2CAP_3_6	False	Support of flush timeout value for unreliable channel (C.5)
TSPC_L2CAP_3_7	False	Support of bi-directional quality of service (QoS) option field (C.1)
TSPC_L2CAP_3_8	False	Negotiate QoS service type (C.5)
TSPC_L2CAP_3_9	False	Negotiate and support service type 'No Traffic' (C.2)
TSPC_L2CAP_3_10	False	Negotiate and support service type 'Best effort' (C.3)
TSPC_L2CAP_3_11	False	Negotiate and support service type 'Gauranteed' (C.2)
TSPC_L2CAP_3_12	True	Support minimum MTU size 23 octets (C.6)
TSPC_L2CAP_3_13	False	Negotiate and support service type 'No traffic' for Extended Flow Specification (C.7)
TSPC_L2CAP_3_14	False	Negotiate and support service type 'Best Effort' for Extended Flow Specification (C.8)
TSPC_L2CAP_3_15	False	Negotiate and support service type 'Guaranteed' for Extended Flow Specification. (C.9)
TSPC_L2CAP_3_16	True	Support Multiple Simultaneous LE Data Channels (C.10)

**SM ICS** PTS version: 8.0.3

M - mandatory

O - optional

#### Role

Parameter Name	Selected	Description
TSPC_SM_1_1	True	Central Role (Initiator) (C.1)
TSPC_SM_1_2	True	Peripheral Role (Responder) (C.2)

#### Security Properties

Parameter Name	Selected	Description
TSPC_SM_2_1	True	Authenticated MITM protection (O)
TSPC_SM_2_2	True	Unauthenticated no MITM protection (C.1)
TSPC_SM_2_3	True	No security requirements (M)
TSPC_SM_2_4	True	OOB supported (O)
TSPC_SM_2_5	True	LE Secure Connections (O)

#### Encryption Key Size

Parameter Name	Selected	Description
TSPC_SM_3_1	True	Encryption Key Size (M)

#### Pairing Method

Parameter Name	Selected	Description
TSPC_SM_4_1	True	Just Works (O)
TSPC_SM_4_2	True	Passkey Entry (C.1)
TSPC_SM_4_3	True	Out of Band (C.1)

### Security Initiation

Parameter Name	Selected	Description
TSPC_SM_5_1	True	Encryption Setup using STK (C.3)
TSPC_SM_5_2	True	Encryption Setup using LTK (O)
TSPC_SM_5_3	True	Peripheral Initiated Security (C.1)
TSPC_SM_5_4	True	Peripheral Initiated Security – Central response (C.2)
TSPC_SM_5_5	False	Link Key Conversion Function h7 (C.4)
TSPC_SM_5_6	False	Link Key Conversion Function h6 (C.5)

### Signing Algorithm

Parameter Name	Selected	Description
TSPC_SM_6_1	True	Signing Algorithm - Generation (O)
TSPC_SM_6_2	True	Signing Algorithm - Resolving (O)

### Key Distribution

Parameter Name	Selected	Description
TSPC_SM_7_1	True	Encryption Key (C.1)
TSPC_SM_7_2	True	Identity Key (C.2)
TSPC_SM_7_3	True	Signing Key (C.3)

### Cross-Transport Key Derivation

Parameter Name	Selected	Description
TSPC_SM_8_1	False	Cross Transport Key Derivation Supported (C.1)
TSPC_SM_8_2	False	Derivation of LE LTK from BR/EDR Link Key (C.2)
TSPC_SM_8_3	False	Derivation of BR/EDR Link Key from LE LTK (C.2)

**RFCOMM PICS** PTS version: 6.4

- different than PTS defaults

### Protocol Version

Parameter Name	Selected	Description
TSPC_RFCOMM_0_1	False	RFCOMM 1.1 with TS 07.10
TSPC_RFCOMM_0_2	True (*)	RFCOMM 1.2 with TS 07.10

### Supported Procedures

Parameter Name	Selected	Description
TSPC_RFCOMM_1_1	True (*)	Initialize RFCOMM Session
TSPC_RFCOMM_1_2	True (*)	Respond to Initialization of an RFCOMM Session
TSPC_RFCOMM_1_3	True	Shutdown RFCOMM Session
TSPC_RFCOMM_1_4	True	Respond to a Shutdown of an RFCOMM Session
TSPC_RFCOMM_1_5	True (*)	Establish DLC
TSPC_RFCOMM_1_6	True (*)	Respond to Establishment of a DLC
TSPC_RFCOMM_1_7	True	Disconnect DLC
TSPC_RFCOMM_1_8	True	Respond to Disconnection of a DLC
TSPC_RFCOMM_1_9	True	Respond to and send MSC Command
TSPC_RFCOMM_1_10	True	Initiate Transfer Information
TSPC_RFCOMM_1_11	True	Respond to Test Command
TSPC_RFCOMM_1_12	False	Send Test Command
TSPC_RFCOMM_1_13	True	React to Aggregate Flow Control
TSPC_RFCOMM_1_14	True	Respond to RLS Command
TSPC_RFCOMM_1_15	False	Send RLS Command
TSPC_RFCOMM_1_16	True	Respond to PN Command
TSPC_RFCOMM_1_17	True (*)	Send PN Command
TSPC_RFCOMM_1_18	True (*)	Send Non-Supported Command (NSC) response
TSPC_RFCOMM_1_19	True	Respond to RPN Command
TSPC_RFCOMM_1_20	False	Send RPN Command
TSPC_RFCOMM_1_21	True (*)	Closing Multiplexer by First Sending a DISC Command
TSPC_RFCOMM_1_22	True	Support of Credit Based Flow Control

**MESH ICS** PTS version: 8.0.3

M - mandatory

O - optional

#### Major Profile Version (X.Y)

Parameter Name	Selected	Description
TSPC_MESH_0_1	True	Mesh v1.0 (M)

#### Minor Profile Version (X.Y.Z)

Parameter Name	Selected	Description
TSPC_MESH_0a_1	True	Erratum 10395 (C.1)
TSPC_MESH_0a_2	True	Mesh v1.0.1 (C.2)
TSPC_MESH_0a_3	True	Erratum 16350 (C.1)

#### Roles

Parameter Name	Selected	Description
TSPC_MESH_2_1	True	Node (C.1)
TSPC_MESH_2_2	False	Provisioner (C.1)

#### Node Capabilities - Bearers

Parameter Name	Selected	Description
TSPC_MESH_3_1	True	Advertising Bearer (C.1)
TSPC_MESH_3_2	True	GATT Bearer (C.1)

**Node Capabilities - Provisioning**

Parameter Name	Selected	Description
TSPC_MESH_4_1	True	PB-ADV (C.1)
TSPC_MESH_4_2	True	PB-GATT (C.2)
TSPC_MESH_4_3	True	Device UUID (C.3)
TSPC_MESH_4_4	True	Sending Unprovisioned Device Beacon (C.4)
TSPC_MESH_4_5	True	Generic Provisioning Layer (C.3)
TSPC_MESH_4_6	True	Provisioning Protocol (Provisioning Server) (C.3)
TSPC_MESH_4_7	False	Provisioning: Public Key OOB (C.5)
TSPC_MESH_4_8	True	Provisioning: Public Key No OOB (C.5)
TSPC_MESH_4_9	True	Provisioning: Authentication Output OOB (C.6)
TSPC_MESH_4_10	False	Provisioning: Authentication Input OOB (C.6)
TSPC_MESH_4_11	False	Provisioning: Authentication Static OOB (C.6)
TSPC_MESH_4_12	True	Provisioning: Authentication No OOB (C.3)

**Node Capabilities – Network Layer**

Parameter Name	Selected	Description
TSPC_MESH_5_1	True	Transmitting and Receiving Secured Network Layer Messages (M)
TSPC_MESH_5_2	True	Relay Feature (C.1)
TSPC_MESH_5_3	True	Network Message Cache (C.2)
TSPC_MESH_5_4	False	Multiple Subnet Support (O)

**Node Capabilities – Lower Transport Layer**

Parameter Name	Selected	Description
TSPC_MESH_6_1	True	Transmitting and Receiving a Lower Transport PDU (M)
TSPC_MESH_6_2	True	Segmentation and Reassembly Behavior (M)
TSPC_MESH_6_3	True	Friend Cache (C.1)

**Node Capabilities – Upper Transport Layer**

Parameter Name	Selected	Description
TSPC_MESH_7_1	True	Transmitting a Secured Access Payload (M)
TSPC_MESH_7_2	True	Receiving a Secured Upper Transport PDU (M)
TSPC_MESH_7_3	True	Friend Feature (C.1)
TSPC_MESH_7_4	True	Low Power Feature (C.1)
TSPC_MESH_7_5	True	Heartbeat (M)

**Node Capabilities – Access Layer**

Parameter Name	Selected	Description
TSPC_MESH_8_1	True	Transmitting and Receiving an Access Layer Message (M)

**Node Capabilities – Security**

Parameter Name	Selected	Description
TSPC_MESH_9_1	True	Message Replay Protection (M)

**Node Capabilities – Mesh Management**

Parameter Name	Selected	Description
TSPC_MESH_10_1	True	Secure Network Beacon (M)
TSPC_MESH_10_2	True	Key Refresh Procedure (M)
TSPC_MESH_10_3	True	IV Update Procedure (M)
TSPC_MESH_10_4	True	IV Index Recovery Procedure (M)

#### Node Capabilities – Foundation Mesh Models

Parameter Name	Selected	Description
TSPC_MESH_11_1	True	Configuration Server Model (M)
TSPC_MESH_11_2	True	Health Server Model (M)
TSPC_MESH_11_3	False	Configuration Client Model (O)
TSPC_MESH_11_4	False	Health Client Model (O)

#### Node Capabilities – Proxy

Parameter Name	Selected	Description
TSPC_MESH_12_1	True	Proxy Server (C.1)
TSPC_MESH_12_2	True	GATT Server (C.2)
TSPC_MESH_12_3	True	Advertising with Network ID (C.2)
TSPC_MESH_12_4	True	Advertising with Node Identity (C.2)
TSPC_MESH_12_5	False	Proxy Client (C.3)
TSPC_MESH_12_6	False	GATT Client (C.4)

#### Mesh GATT Services

Parameter Name	Selected	Description
TSPC_MESH_13_1	True	Mesh Provisioning Service (C.1)
TSPC_MESH_13_2	True	Mesh Proxy Service (C.2)

#### GATT Server Requirements

Parameter Name	Selected	Description
TSPC_MESH_14_1	True	Discover All Primary Services (M)
TSPC_MESH_14_2	True	Discover Primary Services by Service UUID (M)
TSPC_MESH_14_3	True	Write without Response (M)
TSPC_MESH_14_4	True	Notifications (M)
TSPC_MESH_14_5	True	Write Characteristic Descriptors (M)

#### GATT Client Requirements

Parameter Name	Selected	Description
TSPC_MESH_15_1	False	Discover All Primary Services (C.1)
TSPC_MESH_15_2	False	Discover Primary Services by Service UUID (C.1)
TSPC_MESH_15_3	False	Write without Response (M)
TSPC_MESH_15_4	False	Notifications (M)
TSPC_MESH_15_5	False	Write Characteristic Descriptors (M)

**GAP Requirements**

Parameter Name	Selected	Description
TSPC_MESH_16_1	True	Broadcaster (C.1)
TSPC_MESH_16_2	True	Observer (C.1)
TSPC_MESH_16_3	True	Peripheral (C.2)
TSPC_MESH_16_4	True	Peripheral – Security Mode 1 (C.2)
TSPC_MESH_16_5	False	Central (C.3)
TSPC_MESH_16_6	False	Central – Security Mode 1 (C.3)

**Provisioner – Bearers**

Parameter Name	Selected	Description
TSPC_MESH_17_1	False	Advertising Bearer (C.1)
TSPC_MESH_17_2	False	GATT Bearer (C.1)

**Provisioner – Provisioning**

Parameter Name	Selected	Description
TSPC_MESH_18_1	False	Receiving Unprovisioned Device Beacon (C.1)
TSPC_MESH_18_2	False	PB-ADV (C.1)
TSPC_MESH_18_3	False	Generic Provisioning Layer (M)
TSPC_MESH_18_4	False	Provisioning Protocol (Provisioning Client) (M)
TSPC_MESH_18_5	False	PB-GATT (C.2)
TSPC_MESH_18_6	False	GATT Client (C.2)
TSPC_MESH_18_7	False	Provisioning: Public Key OOB (M)
TSPC_MESH_18_8	False	Provisioning: Public Key No OOB (M)
TSPC_MESH_18_9	False	Provisioning: Authentication Output OOB (M)
TSPC_MESH_18_10	False	Provisioning: Authentication Input OOB (M)
TSPC_MESH_18_11	False	Provisioning: Authentication Static or No OOB (M)

**Provisioner – Mesh Management**

Parameter Name	Selected	Description
TSPC_MESH_19_1	False	Receiving Secure Network Beacon (M)

**GATT Client Requirements**

Parameter Name	Selected	Description
TSPC_MESH_20_1	False	Discover All Primary Services (C.1)
TSPC_MESH_20_2	False	Discover Primary Services by Service UUID (C.1)
TSPC_MESH_20_3	False	Write without Response (M)
TSPC_MESH_20_4	False	Notifications (M)
TSPC_MESH_20_5	False	Write Characteristic Descriptors (M)

**GAP Requirements**

Parameter Name	Selected	Description
TSPC_MESH_21_1	False	Broadcaster (C.1)
TSPC_MESH_21_2	False	Observer (C.1)
TSPC_MESH_21_3	False	Central (C.2)
TSPC_MESH_21_4	False	Central - Security Mode 1 (C.2)

DIS ICS PTS version: 8.0.3

M - mandatory

O - optional

#### Service Version

Parameter Name	Selected	Description
TSPC_DIS_0_1	True	Device Information Service v1.1 (M)

#### Transport Requirements

Parameter Name	Selected	Description
TSPC_DIS_1_1	False	Service supported over BR/EDR (C.1)
TSPC_DIS_1_2	True	Service supported over LE (C.1)
TSPC_DIS_1_3	False	Service supported over HS (C.1)

#### Service Requirements

Parameter Name	Selected	Description
TSPC_DIS_2_1	True	Device Information Service (M)
TSPC_DIS_2_2	True	Manufacturer Name String Characteristic (O)
TSPC_DIS_2_3	True	Model Number String Characteristic (O)
TSPC_DIS_2_4	True	Serial Number String Characteristic (O)
TSPC_DIS_2_5	True	Hardware Revision String Characteristic (O)
TSPC_DIS_2_6	True	Firmware Revision String Characteristic (O)
TSPC_DIS_2_7	True	Software Revision String Characteristic (O)
TSPC_DIS_2_8	False	System ID Characteristic (O)
TSPC_DIS_2_9	False	IEEE 11073-20601 Regulatory Certification Data List Characteristic (O)
TSPC_DIS_2_10	False	SDP Interoperability (C.1)
TSPC_DIS_2_11	True	PnP ID (O)

### 8.3.4 Bluetooth tools

This page lists and describes tools that can be used to assist during Bluetooth stack or application development in order to help, simplify and speed up the development process.

#### Mobile applications

It is often useful to make use of existing mobile applications to interact with hardware running Zephyr, to test functionality without having to write any additional code or requiring extra hardware.

The recommended mobile applications for interacting with Zephyr are:

- Android:
  - [nRF Connect for Android](#)
  - [nRF Mesh for Android](#)
  - [LightBlue for Android](#)
- iOS:
  - [nRF Connect for iOS](#)
  - [nRF Mesh for iOS](#)
  - [LightBlue for iOS](#)

## Using BlueZ with Zephyr

The Linux Bluetooth Protocol Stack, BlueZ, comes with a very useful set of tools that can be used to debug and interact with Zephyr's BLE Host and Controller. In order to benefit from these tools you will need to make sure that you are running a recent version of the Linux Kernel and BlueZ:

- Linux Kernel 4.10+
- BlueZ 4.45+

Additionally, some of the BlueZ tools might not be bundled by default by your Linux distribution. If you need to build BlueZ from scratch to update to a recent version or to obtain all of its tools you can follow the steps below:

```
git clone git://git.kernel.org/pub/scm/bluetooth/bluez.git
cd bluez
./bootstrap-configure --disable-android --disable-midi
make
```

You can then find `btattach`, `btmgt` and `btproxy` in the `tools/` folder and `btmon` in the `monitor/` folder. You'll need to enable BlueZ's experimental features so you can access its most recent BLE functionality. Do this by editing the file `/lib/systemd/system/bluetooth.service` and making sure to include the `-E` option in the daemon's execution start line:

```
ExecStart=/usr/libexec/bluetooth/bluetoothd -E
```

Finally, reload and restart the daemon:

```
sudo systemctl daemon-reload
sudo systemctl restart bluetooth
```

## Running on QEMU and Native POSIX

It's possible to run Bluetooth applications using either the [QEMU emulator](#) or Native POSIX. In either case, a Bluetooth controller needs to be exported from the host OS (Linux) to the emulator. For this purpose you will need some tools described in the [Using BlueZ with Zephyr](#) section.

**Using the Host System Bluetooth Controller** The host OS's Bluetooth controller is connected in the following manner:

- To the second QEMU serial line using a UNIX socket. This socket gets used with the help of the QEMU option `-serial unix:/tmp/bt-server-bredr`. This option gets passed to QEMU through `QEMU_EXTRA_FLAGS` automatically whenever an application has enabled Bluetooth support.
- To a serial port in Native POSIX through the use of a command-line option passed to the Native POSIX executable: `--bt-dev=hci0`

On the host side, BlueZ allows you to export its Bluetooth controller through a so-called user channel for QEMU and Native POSIX to use.

---

**Note:** You only need to run `btproxy` when using QEMU. Native POSIX handles the UNIX socket proxying automatically

---

If you are using QEMU, in order to make the Controller available you will need one additional step using `btproxy`:

1. Make sure that the Bluetooth controller is down
2. Use the `btproxy` tool to open the listening UNIX socket, type:

```
sudo tools/btproxy -u -i 0
Listening on /tmp/bt-server-bredr
```

You might need to replace `-i 0` with the index of the Controller you wish to proxy.

Once the hardware is connected and ready to use, you can then proceed to building and running a sample:

- Choose one of the Bluetooth sample applications located in `samples/bluetooth`.
- To run a Bluetooth application in QEMU, type:

```
west build -b qemu_x86 samples/bluetooth/<sample>
west build -t run
```

Running QEMU now results in a connection with the second serial line to the `bt-server-bredr` UNIX socket, letting the application access the Bluetooth controller.

- To run a Bluetooth application in Native POSIX, first build it:

```
west build -b native_posix samples/bluetooth/<sample>
```

And then run it with:

```
$ sudo ./build/zephyr/zephyr.exe --bt-dev=hci0
```

**Using a Zephyr-based BLE Controller** Depending on which hardware you have available, you can choose between two transports when building a single-mode, Zephyr-based BLE Controller:

- UART: Use the `hci_uart` sample and follow the instructions in `bluetooth-hci-uart-qemu-posix`.
- USB: Use the `hci_usb` sample and then treat it as a Host System Bluetooth Controller (see previous section)

**HCI Tracing** When running the Host on a computer connected to an external Controller, it is very useful to be able to see the full log of exchanges between the two, in the format of a [Host Controller Interface](#) log. In order to see those logs, you can use the built-in `btmon` tool from BlueZ:

```
$ btmon
```

### Using Zephyr-based Controllers with BlueZ

If you want to test a Zephyr-powered BLE Controller using BlueZ's Bluetooth Host, you will need a few tools described in the [Using BlueZ with Zephyr](#) section. Once you have installed the tools you can then use them to interact with your Zephyr-based controller:

```
sudo tools/btmgmt --index 0
[hci0]# auto-power
[hci0]# find -l
```

You might need to replace `--index 0` with the index of the Controller you wish to manage. Additional information about `btmgmt` can be found in its manual pages.

## 8.3.5 Developing Bluetooth Applications

Bluetooth applications are developed using the common infrastructure and approach that is described in the [Application Development](#) section of the documentation.

Additional information that is only relevant to Bluetooth applications can be found in this page.

## Hardware setup

This section describes the options you have when building and debugging Bluetooth applications with Zephyr. Depending on the hardware that is available to you, the requirements you have and the type of development you prefer you may pick one or another setup to match your needs.

There are 4 possible hardware setups to use with Zephyr and Bluetooth:

1. Embedded
2. QEMU with an external Controller
3. Native POSIX with an external Controller
4. Simulated nRF52 with BabbleSim

**Embedded** This setup relies on all software running directly on the embedded platform(s) that the application is targeting. All the [Configurations](#) and [Build Types](#) are supported but you might need to build Zephyr more than once if you are using a dual-chip configuration or if you have multiple cores in your SoC each running a different build type (e.g., one running the Host, the other the Controller).

To start developing using this setup follow the [Getting Started Guide](#), choose one (or more if you are using a dual-chip solution) boards that support Bluetooth and then [run the application](#).

**Embedded HCI tracing** When running both Host and Controller in actual Integrated Circuits, you will only see normal log messages on the console by default, without any way of accessing the HCI traffic between the Host and the Controller. However, there is a special Bluetooth logging mode that converts the console to use a binary protocol that interleaves both normal log messages as well as the HCI traffic. Set the following Kconfig options to enable this protocol before building your application:

```
CONFIG_BT_DEBUG_MONITOR_UART=y
CONFIG_UART_CONSOLE=n
```

Setting `:kconfig: `CONFIG_BT_DEBUG_MONITOR_UART`` to `y` replaces the `:kconfig: `CONFIG_BT_DEBUG_LOG`` option, and setting `:kconfig: `CONFIG_UART_CONSOLE`` to `n` disables the default `printf`/`printk` hooks.

To decode the binary protocol that will now be sent to the console UART you need to use the `btmon` tool from [BlueZ](#):

```
$ btmon --tty <console TTY> --tty-speed 115200
```

## Host on Linux with an external Controller

**Note:** This is currently only available on GNU/Linux

This setup relies on a “dual-chip” [configuration](#) which is comprised of the following devices:

1. A [Host-only](#) application running in the [QEMU](#) emulator or the `native_posix` native port of Zephyr
2. A Controller, which can be one of two types:
  - A commercially available Controller
  - A [Controller-only](#) build of Zephyr

**Warning:** Certain external Controllers are either unable to accept the Host to Controller flow control parameters that Zephyr sets by default (Qualcomm), or do not transmit any data from the Controller to the Host (Realtek). If you see a message similar to:

```
<wrn> bt_hci_core: opcode 0x0c33 status 0x12
```

when booting your sample of choice (make sure you have enabled **:kconfig: `CONFIG_BT_DEBUG_LOG`** in your `prj.conf` before running the sample), or if there is no data flowing from the Controller to the Host, then you need to disable Host to Controller flow control. To do so, set `CONFIG_BT_HCI_ACL_FLOW_CONTROL=n` in your `prj.conf`.

**QEMU** You can run the Zephyr Host on the [QEMU emulator](#) and have it interact with a physical external Bluetooth Controller. Refer to [Running on QEMU and Native POSIX](#) for full instructions on how to build and run an application in this setup.

---

### Native POSIX

**Note:** This is currently only available on GNU/Linux

---

The Native POSIX target builds your Zephyr application with the Zephyr kernel, and some minimal HW emulation as a native Linux executable. This executable is a normal Linux program, which can be debugged and instrumented like any other, and it communicates with a physical external Controller.

Refer to [Running on QEMU and Native POSIX](#) for full instructions on how to build and run an application in this setup.

---

### Simulated nRF52 with BabbleSim

**Note:** This is currently only available on GNU/Linux

---

The `nrf52_bsim` board, is a simulated target board which emulates the necessary peripherals of a nrf52 SOC to be able to develop and test BLE applications. This board, uses:

- [BabbleSim](#) to simulate the nrf52 modem and the radio environment.
- The POSIX arch to emulate the processor.
- [Models of the nrf52 HW](#)

Just like with the `native_posix` target, the build result is a normal Linux executable. You can find more information on how to run simulations with one or several devices in this board's documentation

Currently, only [Combined builds](#) are possible, as this board does not yet have any models of a UART, or USB which could be used for an HCI interface towards another real or simulated device.

### Initialization

The Bluetooth subsystem is initialized using the `bt_enable()` function. The caller should ensure that function succeeds by checking the return code for errors. If a function pointer is passed to `bt_enable()`, the initialization happens asynchronously, and the completion is notified through the given function.

### Bluetooth Application Example

A simple Bluetooth beacon application is shown below. The application initializes the Bluetooth Subsystem and enables non-connectable advertising, effectively acting as a Bluetooth Low Energy broadcaster.

```

1  /*
2  3  * Set Advertisement data. Based on the Eddystone specification:
4  * https://github.com/google/eddystone/blob/master/protocol-specification.md
5  * https://github.com/google/eddystone/tree/master/eddystone-url
6  */
7  static const struct bt_data ad[] = {
8      BT_DATA_BYTES(BT_DATA_FLAGS, BT_LE_AD_NO_BREDR),
9      BT_DATA_BYTES(BT_DATA_UUID16_ALL, 0xaa, 0xfe),
10     BT_DATA_BYTES(BT_DATA_SVC_DATA16,
11         0xaa, 0xfe, /* Eddystone UUID */
12         0x10, /* Eddystone-URL frame type */
13         0x00, /* Calibrated Tx power at 0m */
14         0x00, /* URL Scheme Prefix http://www. */
15         'z', 'e', 'd', 'd', 'y', 's', 't', 'o', 'n', 'e',
16         'p', 'r', 'o', 'j', 'e', 'c', 't',
17         0x08) /* .org */
18 };
19
20 /* Set Scan Response data */
21 static const struct bt_data sd[] = {
22     BT_DATA(BT_DATA_NAME_COMPLETE, DEVICE_NAME, DEVICE_NAME_LEN),
23 };
24
25 static void bt_ready(int err)
26 {
27     char addr_s[BT_ADDR_LE_STR_LEN];
28     bt_addr_le_t addr = {0};
29     size_t count = 1;
30
31     if (err) {
32         printk("Bluetooth init failed (err %d)\n", err);
33         return;
34     }
35
36     printk("Bluetooth initialized\n");
37
38     /* Start advertising */
39     err = bt_le_adv_start(BT_LE_ADV_NCONN_IDENTITY, ad, ARRAY_SIZE(ad),
40         sd, ARRAY_SIZE(sd));
41     if (err) {
42         printk("Advertising failed to start (err %d)\n", err);
43         return;
44     }
45
46     /* For connectable advertising you would use
47     * bt_le_oob_get_local(). For non-connectable non-identity
48     * advertising an non-resolvable private address is used;
49     * there is no API to retrieve that.
50     */
51
52     bt_id_get(&addr, &count);
53     bt_addr_le_to_str(&addr, addr_s, sizeof(addr_s));
54
55     printk("Beacon started, advertising as %s\n", addr_s);
56 }

```

(continues on next page)

(continued from previous page)

```
58
59 void main(void)
60 {
61     int err;
62
63     printk("Starting Beacon Demo\n");
64
65     /* Initialize the Bluetooth Subsystem */
66     err = bt_enable(bt_ready);
67     if (err) {
68         printk("Bluetooth init failed (err %d)\n", err);
69     }
70 }
```

The key APIs employed by the beacon sample are `bt_enable()` that's used to initialize Bluetooth and then `bt_le_adv_start()` that's used to start advertising a specific combination of advertising and scan response data.

### 8.3.6 AutoPTS on Windows 10 with nRF52 board

#### Overview

This tutorial shows how to setup AutoPTS client and server to run both on Windows 10. We use WSL1 with Ubuntu only to build a Zephyr project to an elf file, because Zephyr SDK is not available on Windows yet. Tutorial covers only nrf52840dk.

#### Update Windows and drivers

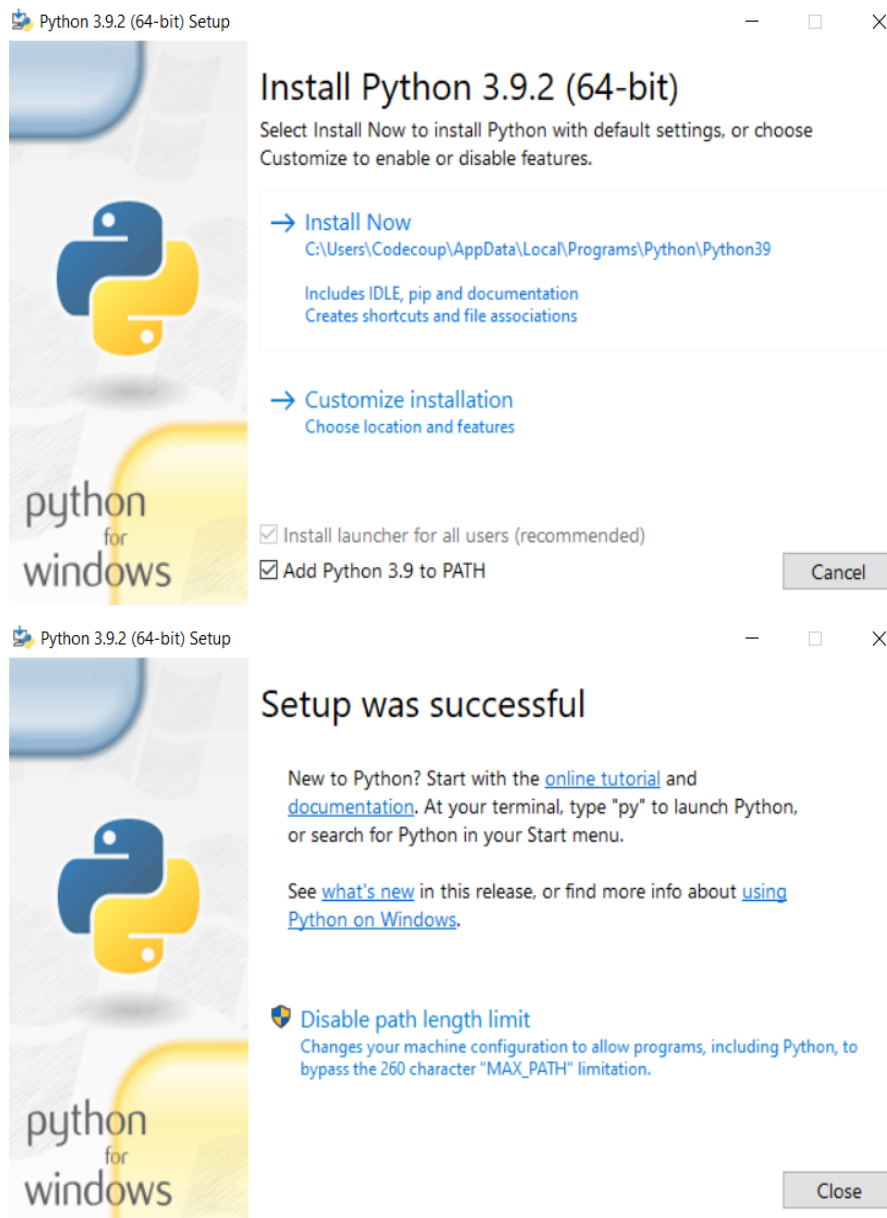

Update Windows in:

Start -> Settings -> Update & Security -> Windows Update

Update drivers, following the instructions from your hardware vendor.

#### Install Python 3

Download and install [Python 3](#). Setup was tested with versions  $\geq 3.8$ . Let the installer add the Python installation directory to the PATH and disable the path length limitation.

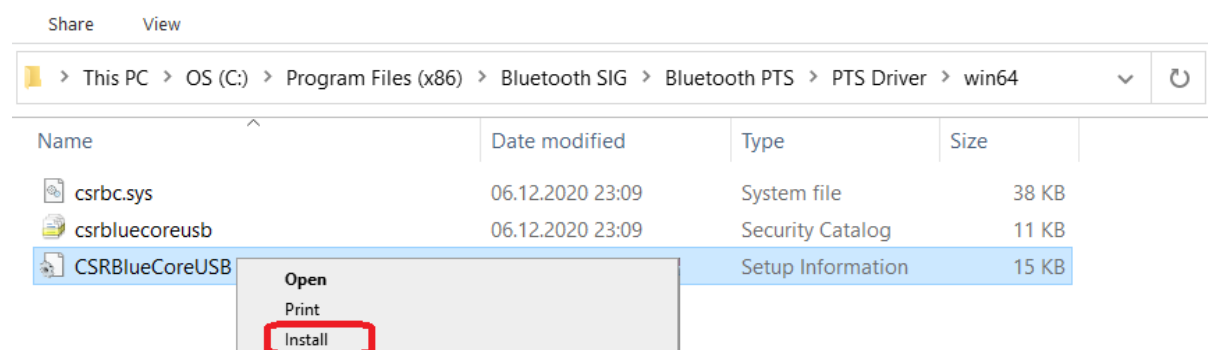

## Install Git

Download and install [Git](#). During installation enable option: Enable experimental support for pseudo consoles. We will use Git Bash as Windows terminal.

## Install PTS 8

Install latest PTS from <https://www.bluetooth.org>. Remember to install drivers from installation directory “C:/Program Files (x86)/Bluetooth SIG/Bluetooth PTS/PTS Driver/win64/CSRBlueCoreUSB.inf”

**Note:** Starting with PTS 8.0.1 the Bluetooth Protocol Viewer is no longer included. So to capture Bluetooth events, you have to download it separately.

---

## Setup Zephyr project for Windows

Setup from Zephyr site [https://docs.zephyrproject.org/latest/getting\\_started/index.html](https://docs.zephyrproject.org/latest/getting_started/index.html):

Open Git Bash and go to home:

```
cd ~
```

Install west:

```
pip3 install west
```

Get the Zephyr source code:

```
west init zephyrproject
```

Go into freshly created folder:

```
cd zephyrproject
```

Run:

```
west update
```

Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications:

```
west zephyr-export
```

Zephyr's scripts/requirements.txt file declares additional Python dependencies. Install them with pip:

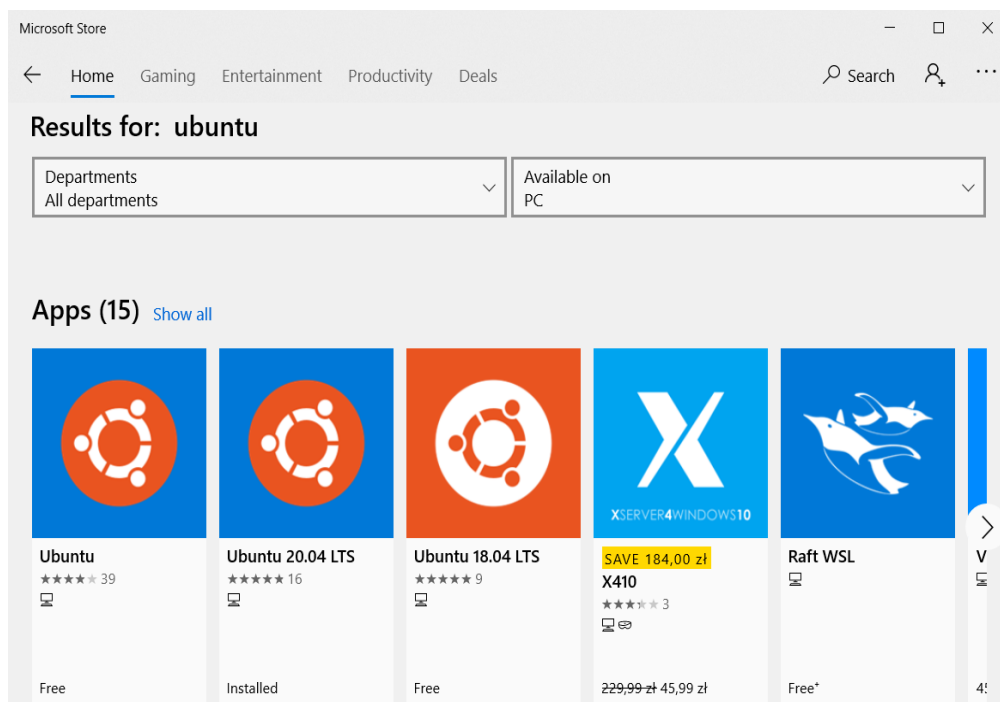

```
pip3 install -r ~\zephyrproject\zephyr\scripts\requirements.txt
```

## Setup WSL1 with Ubuntu 20.4

Setup Install Ubuntu 20.4 on [WSL1](#). Open PowerShell as Administrator and run:

```
dism.exe /online /enable-feature /featurename:Microsoft-Windows-Subsystem-Linux /all /
↵norestart
```

Restart Windows. After restart, open Microsoft Store and install Ubuntu 20.4 LTS.

Run Ubuntu. You will be asked to create a user account and password:

When finished, run commands:

```
sudo apt update
sudo apt upgrade
```

Install python3:

```
sudo apt install python3
```

Install pip:

```
sudo apt install python3-pip
```

Install west:

```
pip3 install --user -U west
```

Export local bin to PATH:

```
echo 'export PATH=~/.local/bin:$PATH' >> ~/.bashrc
```

Reload PATH:

```
source ~/.bashrc
```

Install cmake:

```
sudo apt install cmake
```

Go to your zephyrproject:

```
cd /mnt/c/Users/Codecoup/zephyrproject
```

and then run:

```
west zephyr-export
pip3 install --user wheel
pip3 install --user -r /mnt/c/Users/codecoup/zephyrproject/zephyr/scripts/
↳ requirements.txt
```

Check if all modules have been installed:

```
pip3 list
```

If modules still will be missing, just install them with:

```
pip3 install <module_name>
```

Install Ninja:

```
pip3 install ninja
```

Go to home:

```
cd ~
```

Download latest toolchain installer from <https://github.com/zephyrproject-rtos/sdk-ng/releases>. Move it to ~

```
mv /mnt/c/Users/Codecoup/Downloads/zephyr-sdk-<your_version>-setup.run ~
```

Give permissions to the installer:

```
chmod +x zephyr-sdk-<your_version>-setup.run
```

and run the installer:

```
./zephyr-sdk-<your_version>-setup.run -- -d ~/zephyr-sdk-<your_version>
```

Copy rules:

```
sudo cp ~/zephyr-sdk-<your_version>/sysroots/x86_64-pokysdk-linux/usr/share/openocd/  
↪ contrib/60-openocd.rules /etc/udev/rules.d
```

Restart the Ubuntu machine. You may want to shutdown all WSL consoles from Windows's Git Bash:

```
wsl --shutdown
```

After Ubuntu restart, go to:

```
cd /mnt/c/Users/codecoup/zephyrproject
```

and test if west can build:

```
west build -p auto -b nrf52840dk_nrf52840 zephyr/tests/bluetooth/tester/
```

From now on, you can build projects by typing in Windows's Git Bash:

```
wsl -d Ubuntu-20.04 -u codecoup -- bash -c -i "cd /mnt/c/Users/Codecoup/zephyrproject/  
↪ ; west build -p auto -b nrf52840dk_nrf52840 zephyr/tests/bluetooth/tester/"
```

## Install nrftools

On Windows download latest nrftools (version  $\geq$  10.12.1) from site <https://www.nordicsemi.com/Software-and-tools/Development-Tools/nRF-Command-Line-Tools/Download> and run default install.

← → ↻ <https://www.nordicsemi.com/Software-and-tools/Development-Tools/nRF-Comma...> ☆ 📄

## Connect devices

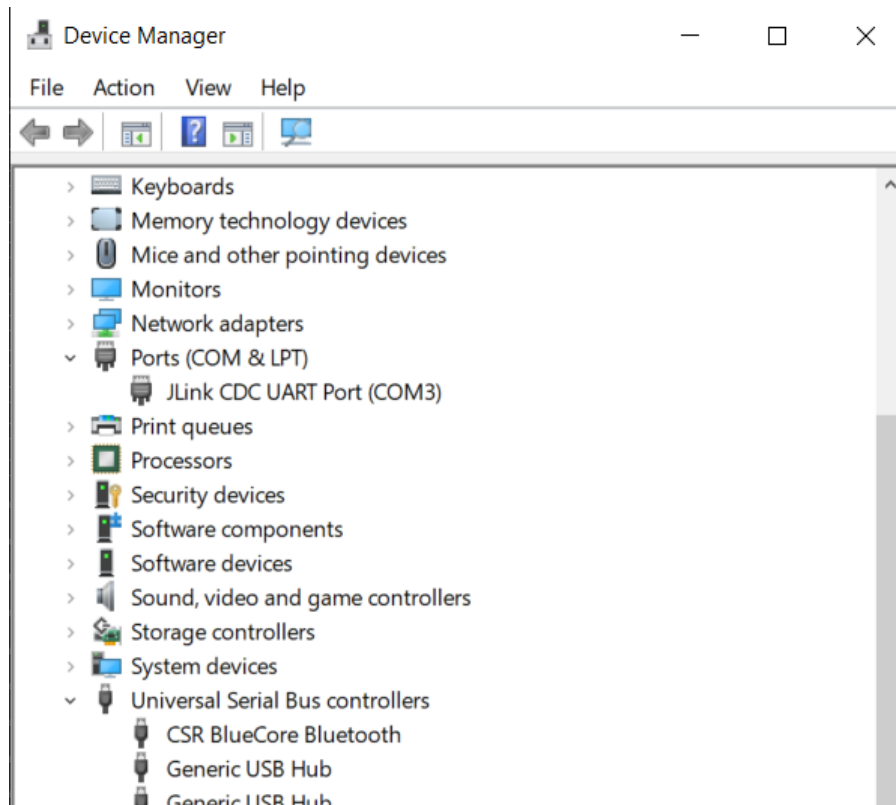

### Flash board

In Device Manager find COM port of your nrf board. In my case it is COM3.

In Git Bash, go to zephyrproject

```
cd ~/zephyrproject
```

You can display flashing options with:

```
west flash --help
```

and flash board with built earlier elf file:

```
west flash --skip-rebuild --board-dir /dev/ttyS2 --elf-file ~/zephyrproject/build/  
↪zephyr/zephyr.elf
```

Note that west does not accept COMs, so use /dev/ttyS2 as the COM3 equivalent, /dev/ttyS2 as the COM3 equivalent, etc.(/dev/ttyS + decremented COM number).

### Setup auto-pts project

In Git Bash, clone project repo:

```
git clone https://github.com/intel/auto-pts.git
```

Go into the project folder:

```
cd auto-pts
```

Install required python modules:

```
pip3 install --user wheel  
pip3 install --user -r autoptsserver_requirements.txt  
pip3 install --user -r autoptsclient_requirements.txt
```

## Install socat.exe

Download and extract socat.exe from <https://sourceforge.net/projects/unix-utils/files/socat/1.7.3.2/> into folder `~/socat-1.7.3.2-1-x86_64/`.

Add path to directory of socat.exe to PATH:

## Running AutoPTS

Server and client by default will run on localhost address. Run server:

```
python ./autoptsserver.py -S 65000
```

```
MINGW64:/c/Users/Codecouple/auto-pts
Codecouple@rakieta3 MINGW64 ~/auto-pts (master)
$ python ./autoptsserver.py -S 65000
Local IP address: ('192.168.9.109', 'fe80::d7a:7f5e:137d:3af4') DNS 'cc.local'
Starting PTS ...
OK
Serving on port 65000 ...
192.168.9.109 - - [31/Mar/2021 12:27:44] "POST / HTTP/1.1" 200 -
192.168.9.109 - - [31/Mar/2021 12:27:44] "POST / HTTP/1.1" 200 -
192.168.9.109 - - [31/Mar/2021 12:27:44] "POST / HTTP/1.1" 200 -
```

**Note:** If the error “ImportError: No module named pywintypes” appeared after the fresh setup, uninstall and install the pywin32 module:

```
pip install --upgrade --force-reinstall pywin32
```

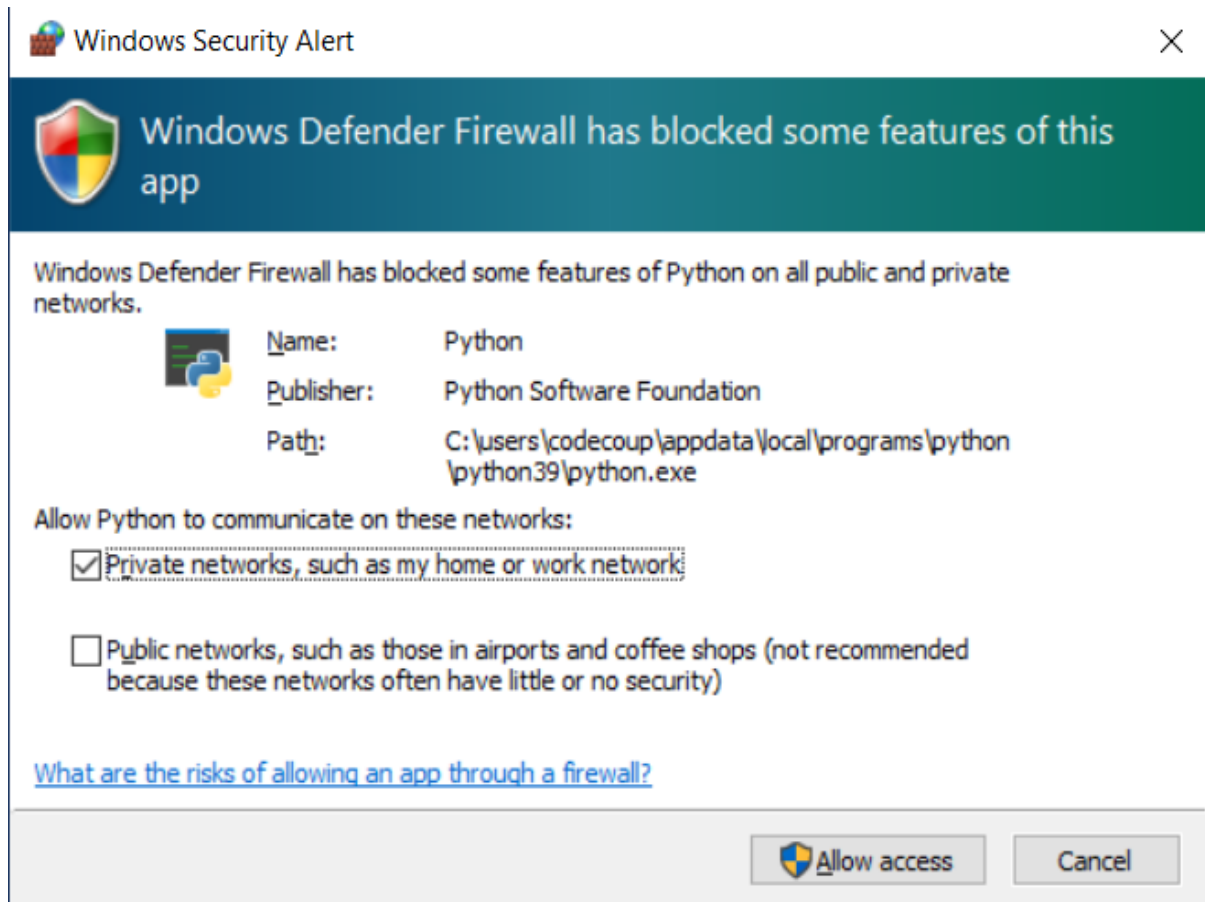

Run client:

```
python ./autoptsclient-zephyr.py zephyr-master ~/zephyrproject/build/zephyr/zephyr.elf -t COM3 -b nrf52 -S 65000 -C 65001
```

```
MINGW64:/c/Users/Codecouple/auto-pts
Codecouple@rakieta3 MINGW64 ~/auto-pts (master)
$ python ./autoptsclient-zephyr.py zephyr-master ~/zephyrproject/build/zephyr/zephyr.elf -t COM3 -b nrf52 -S 65000 -C 65001
(2291946858960) Starting PTS 127.0.0.1 ...
(2291946858960) OK
1/566 GAP GAP/BROB/BCST/BV-01-C PASS 18.667
2/566 GAP GAP/BROB/BCST/BV-02-C PASS 17.081
3/566 GAP GAP/BROB/BCST/BV-03-C INCONC 21.64
4/566 GAP GAP/BROB/BCST/BV-04-C PASS 18.667
```

At the first run, when Windows asks, enable connection through firewall:

### Troubleshooting

- “When running actual hardware test mode, I have only BTP TIMEOUTs.”

This is a problem with connection between auto-pts client and board. There are many possible causes. Try:

- Clean your auto-pts and zephyr repos with

**Warning:** This command will force the irreversible removal of all uncommitted files in the repo.

```
git clean -fdx
```

then build and flash tester elf again.

- If you have set up Windows on virtual machine, check if guest extensions are installed properly or change USB compatibility mode in VM settings to USB 2.0.
- Check, if firewall is not blocking python.exe or socat.exe.
- Check if board sends ready event after restart (hex 00 00 80 ff 00 00). Open serial connection to board with e.g. PuTTY with proper COM and baud rate. After board reset you should see some strings in console.
- Check if socat.exe creates tunnel to board. Run in console

```
socat.exe -x -v tcp-listen:65123 /dev/ttyS2,raw,b115200
```

where /dev/ttyS2 is the COM3 equivalent. Open PuTTY, set connection type to Raw, IP to 127.0.0.1, port to 65123. After board reset you should see some strings in console.

### 8.3.7 AutoPTS on Linux

#### Overview

This tutorial shows how to setup AutoPTS client on Linux with AutoPTS server running on Windows 10 virtual machine. Tested with Ubuntu 20.4 and Linux Mint 20.4.

Supported methods to test zephyr bluetooth host:

- Testing Zephyr Host Stack on QEMU
- Testing Zephyr Host Stack on native posix
- Testing Zephyr combined (controller + host) build on Real hardware (such as nRF52)

**For running with QEMU or native posix, please visit:** [https://docs.zephyrproject.org/latest/guides/bluetooth/bluetooth-tools.html?highlight=hci\\_uart#running-on-qemu-and-native-posix](https://docs.zephyrproject.org/latest/guides/bluetooth/bluetooth-tools.html?highlight=hci_uart#running-on-qemu-and-native-posix)

#### Setup Linux

**Setup Zephyr project** Do the setup from Zephyr site [https://docs.zephyrproject.org/latest/getting\\_started/index.html](https://docs.zephyrproject.org/latest/getting_started/index.html), especially:

**Update OS** This guide covers Ubuntu version 18.04 LTS and later.

```
sudo apt update
sudo apt upgrade
```

#### Install dependencies

```
sudo apt install --no-install-recommends git cmake ninja-build gperf \
ccache dfu-util device-tree-compiler wget \
python3-dev python3-pip python3-setuptools python3-tk python3-wheel xz-utils file \
make gcc gcc-multilib g++-multilib libsdl2-dev
```

**Get Zephyr and install Python dependencies** Install west, and make sure ~/.local/bin is on your PATH environment variable:

```
pip3 install --user -U west
echo 'export PATH=~/.local/bin:"$PATH"' >> ~/.bashrc
source ~/.bashrc
```

Get the Zephyr source code:

```
west init ~/zephyrproject
cd ~/zephyrproject
west update
```

Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications:

```
west zephyr-export
```

Zephyr's scripts/requirements.txt file declares additional Python dependencies. Install them with pip3:

```
pip3 install --user -r ~/zephyrproject/zephyr/scripts/requirements.txt
```

**Install a Toolchain** A toolchain provides a compiler, assembler, linker, and other programs required to build Zephyr applications.

Download the latest SDK installer from <https://github.com/zephyrproject-rtos/sdk-ng/releases> and run the installer, installing the SDK in `~/zephyr-sdk-<your_version>`, e.g.:

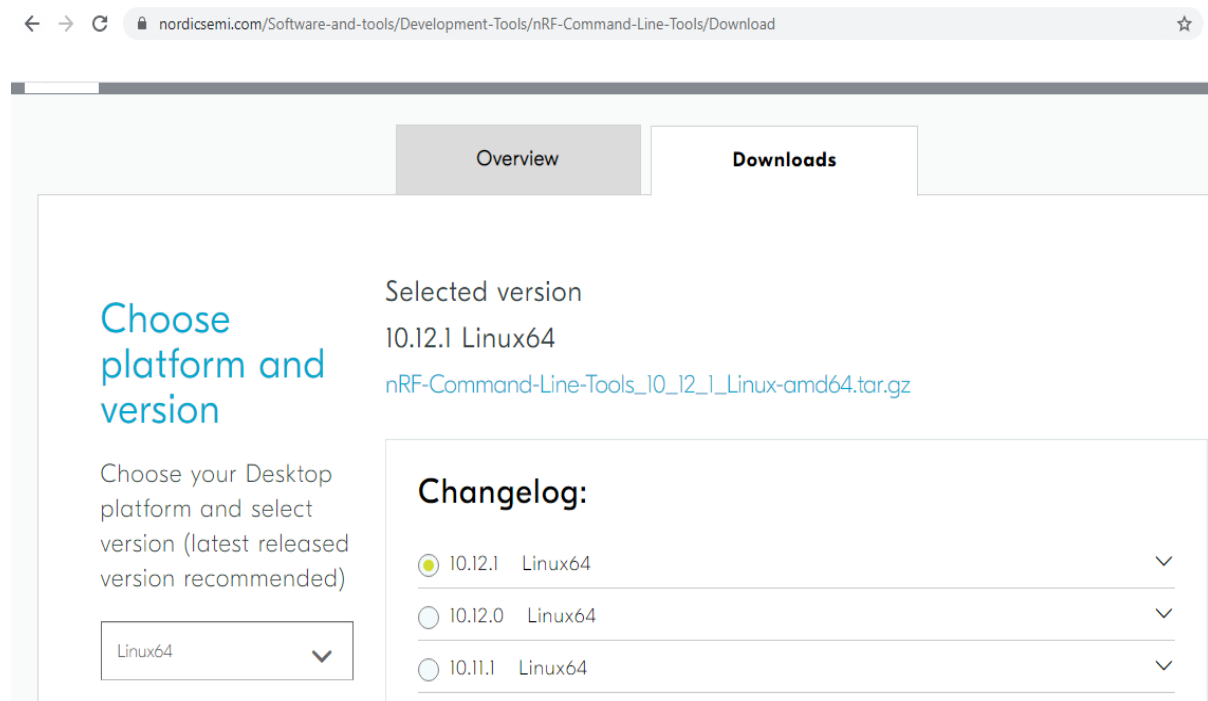

```
chmod +x zephyr-sdk-<your_version>-setup.run
./zephyr-sdk-<your_version>-setup.run -- -d ~/zephyr-sdk-<your_version>
```

Install udev rules, which allow you to flash most Zephyr boards as a regular user:

```
sudo cp ~/zephyr-sdk-<your_version>/sysroots/x86_64-pokysdk-linux/usr/share/openocd/
contrib/60-openocd.rules /etc/udev/rules.d
sudo udevadm control --reload
```

### Install nrftools (only required in the actual hardware test mode)

Download latest nrftools (version `>= 10.12.1`) from site <https://www.nordicsemi.com/Software-and-tools/Development-Tools/nRF-Command-Line-Tools/Download>.

After you extract archive, you will see 2 .deb files, e.g.:

- JLink\_Linux\_V688a\_x86\_64.deb
- nRF-Command-Line-Tools\_10\_12\_1\_Linux-amd64.deb

and README.md. To install the tools, double click on each .deb file or follow instructions from README.md.

### Setup Windows 10 virtual machine

Choose and install your hypervisor like VMWare Workstation(preferred) or VirtualBox. On VirtualBox could be some issues, if your host has fewer than 6 CPU.

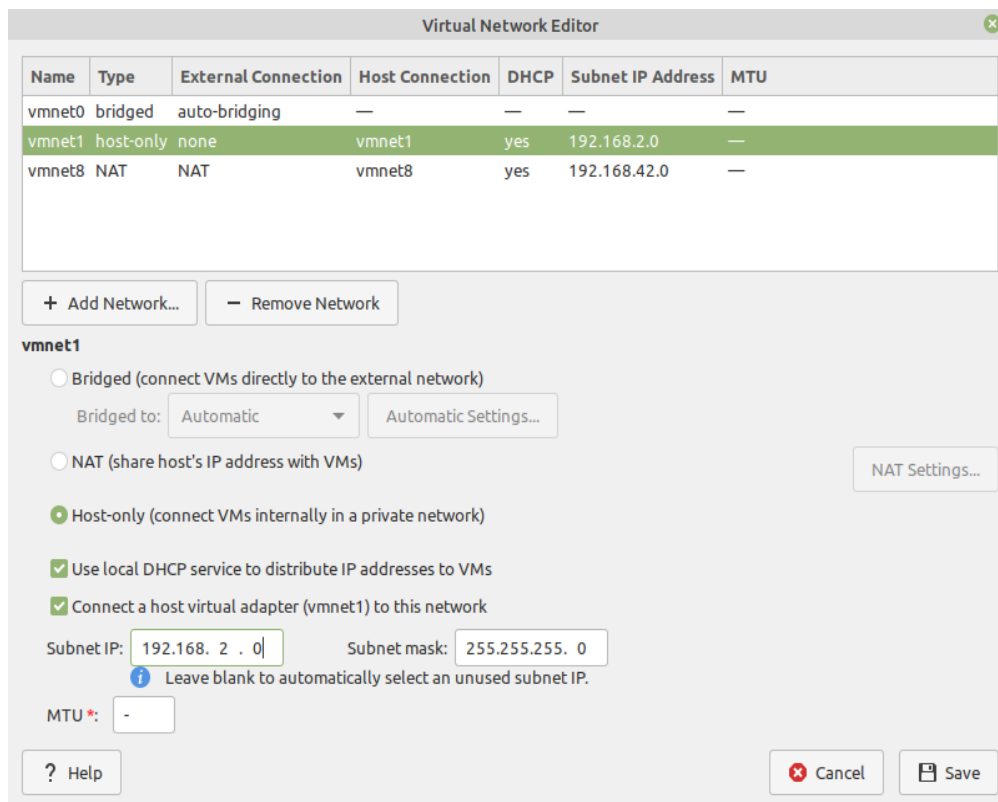

Create Windows virtual machine instance. Make sure it has at least 2 cores and installed guest extensions. Setup tested with VirtualBox 6.1.18 and VMWare Workstation 16.1.1 Pro.

**Update Windows** Update Windows in:

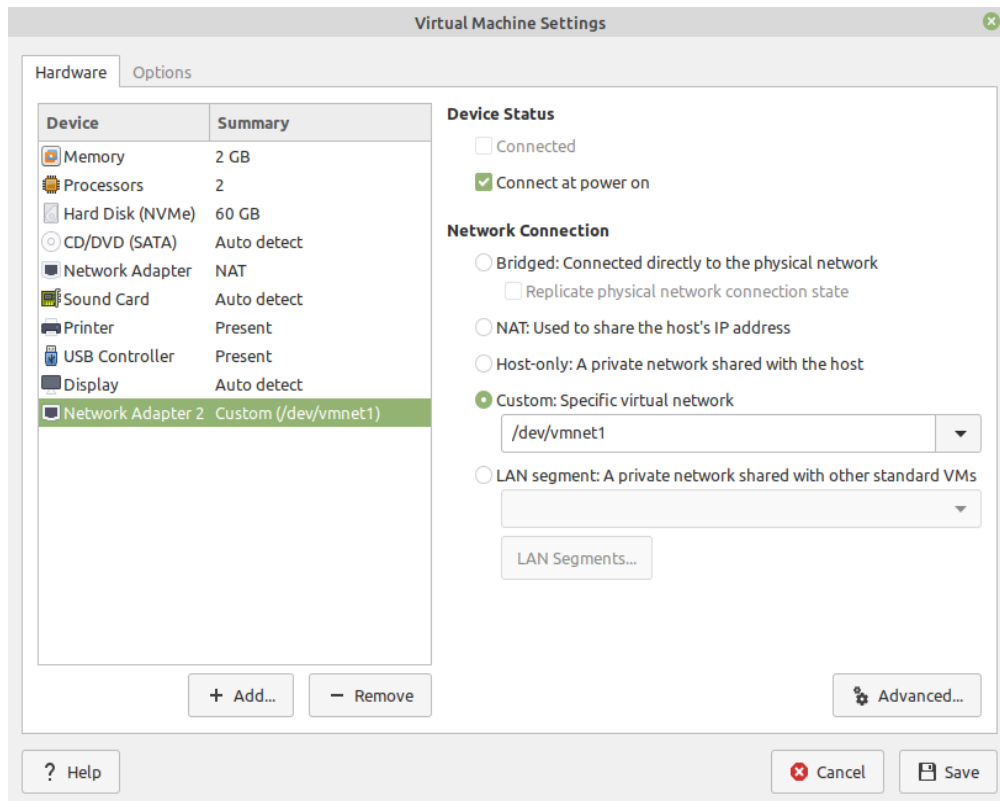

Start -> Settings -> Update & Security -> Windows Update

**Setup static IP**

**WMWare Works** On Linux, open Virtual Network Editor app and create network:

Open virtual machine network settings. Add custom adapter:

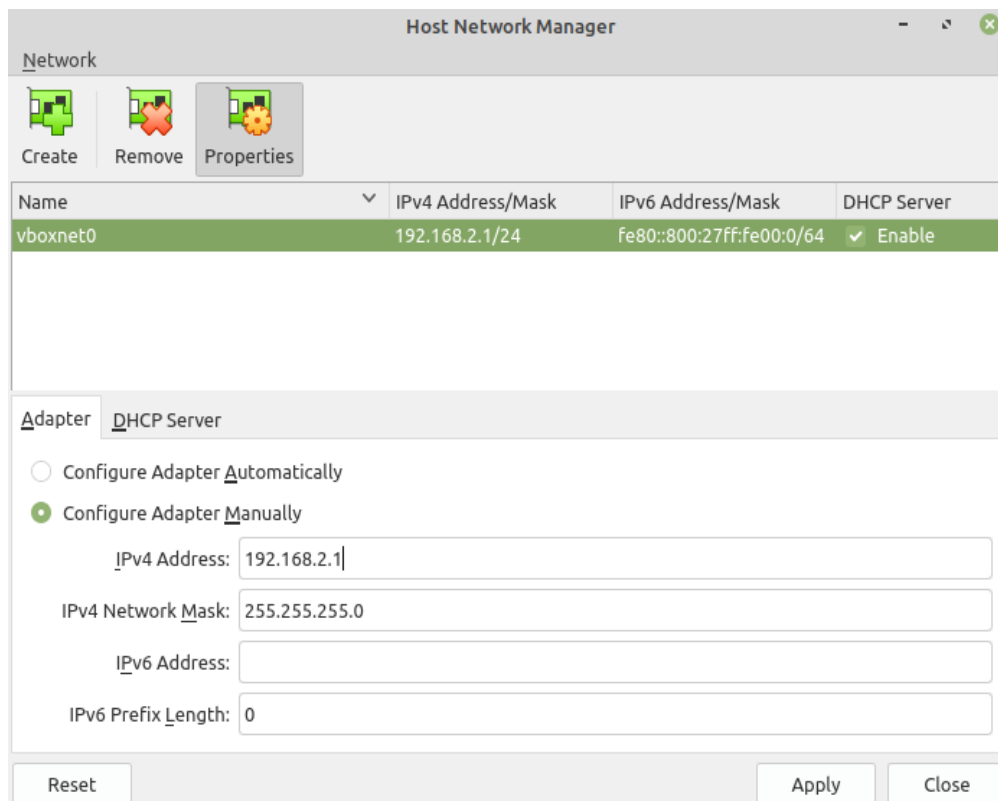

If you type 'ifconfig' in terminal, you should be able to find your host IP:

```
vmnet1: flags=4163<UP, BROADCAST, RUNNING, MULTICAST> mtu 1500
    inet 192.168.2.1 netmask 255.255.255.0 broadcast 192.168.2.255
    inet6 fe80::250:56ff:fec0:1 prefixlen 64 scopeid 0x20<link>
    ether 00:50:56:c0:00:01 txqueuelen 1000 (Ethernet)
    RX packets 0 bytes 0 (0.0 B)
    RX errors 0 dropped 0 overruns 0 frame 0
    TX packets 42 bytes 0 (0.0 B)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0
```

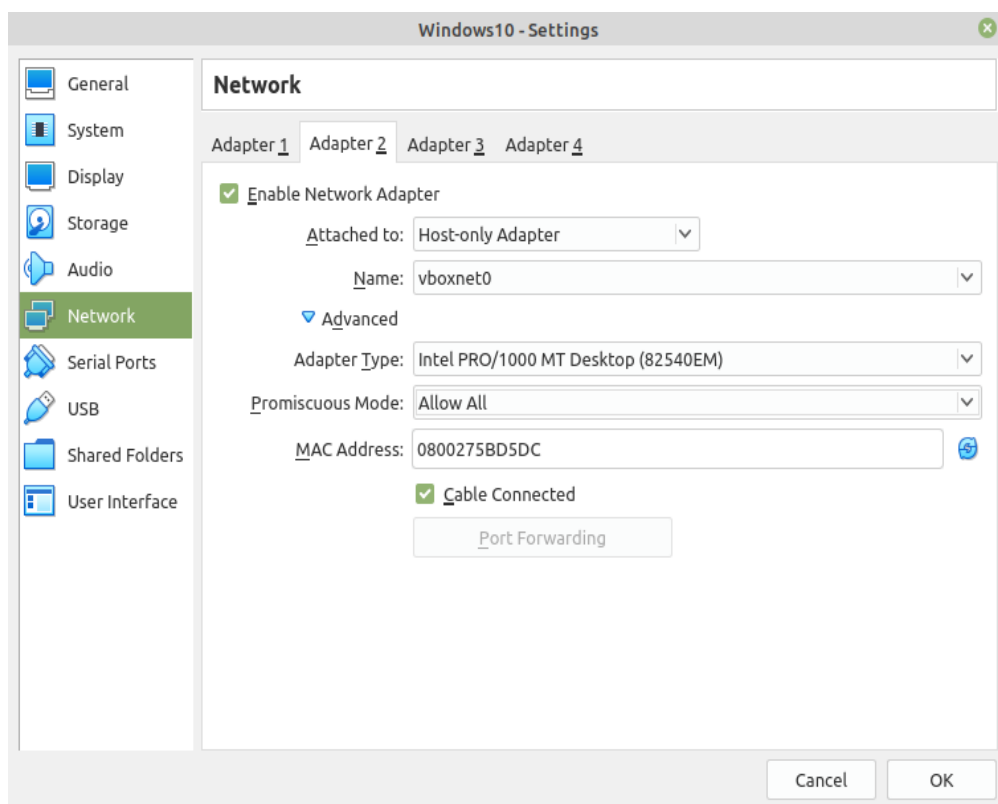

**VirtualBox** Go to:

File -> Host Network Manager

and create network:

Open virtual machine network settings. On adapter 1 you will have created by default NAT. Add adapter 2:

**Windows** Setup static IP on Windows virtual machine. Go to Settings -> Network & Internet -> Ethernet -> Unidentified network -> Edit

and set:

← Settings

Unidentified

**Install Python 3** Download and install latest [Python 3](#) on Windows. Let the installer add the Python installation directory to the PATH and disable the path length limitation.

**Install Git** Download and install [Git](#). During installation enable option: Enable experimental support for pseudo consoles. We will use Git Bash as Windows terminal.

**Install PTS 8** On Windows virtual machine, install latest PTS from <https://www.bluetooth.org>. Remember to install drivers from installation directory "C:/Program Files (x86)/Bluetooth SIG/Bluetooth PTS/PTS Driver/win64/CSRBlueCoreUSB.inf"

**Note:** Starting with PTS 8.0.1 the Bluetooth Protocol Viewer is no longer included. So to capture Bluetooth events, you have to download it separately.

**Connect PTS dongle** With VirtualBox there should be no problem. Just find dongle in Devices -> USB and connect.

With VMWare you might need to use some trick, if you cannot find dongle in VM -> Removable Devices. Type in Linux terminal:

```
usb-devices
```

and find in output your PTS Bluetooth USB dongle

```
T: Bus=01 Lev=01 Prnt=01 Port=01 Cnt=01 Dev#= 6 Spd=12 MxCh= 0
D: Ver= 2.00 Cls=e0(wlcon) Sub=01 Prot=01 MxPS=64 #Cfgs= 1
P: Vendor=0a12 ProdID=0001 Rev=25.20
S: Product=CSR rck PTS Dongle
C: #Ifs= 3 Cfg#= 1 Atr=c0 MxPwr=0mA
T: If#= 0x0 Alt= 0 #EPs= 3 Cls=e0(wlcon) Sub=01 Prot=01 Driver=btusb
```

Note Vendor and ProdID number. Close VMWare Workstation and open .vmx of your virtual machine (path similar to /home/codecoup/vmware/Windows 10/Windows 10.vmx) in text editor. Write anywhere in the file following line:

```
usb.autoConnect.device0 = "0x0a12:0x0001"
```

just replace 0x0a12 with Vendor number and 0x0001 with ProdID number you found earlier.

Connect devices (only required in the actual hardware test mode)

Flash board (only required in the actual hardware test mode)

On Linux, go to `~/zephyrproject`. There should be already `~/zephyrproject/build` directory. Flash board:

```
west flash
```

Setup auto-pts project

AutoPTS client on Linux   Clone auto-pts project:

```
git clone https://github.com/intel/auto-pts.git
```

Install socat, that is used to transfer BTP data stream from UART's tty file:

```
sudo apt-get install python-setuptools socat
```

Install required python modules:

```
cd auto-pts
pip3 install --user wheel
pip3 install --user -r autoptsclient_requirements.txt
```

**Autopts server on Windows virtual machine** In Git Bash, clone auto-pts project repo:

```
git clone https://github.com/intel/auto-pts.git
```

Install required python modules:

```
cd auto-pts
pip3 install --user wheel
pip3 install --user -r autoptsserver_requirements.txt
```

Restart virtual machine.

## Running AutoPTS

Server and client by default will run on localhost address. Run server:

```
python ./autoptsserver.py
```

```
codecou@DESKTOP-5SFTBGB MINGW64 ~/auto-pts (master)
$ python ./autoptsserver.py
Local IP address: ('10.0.2.15', 'fe80::ccb2:6ca1:6368:342a') DNS 'home'
Local IP address: ('192.168.2.2', 'fe80::fd12:15d5:2ddb:9147') DNS None
Starting PTS ...
OK
Serving on port 65000 ...
```

Testing Zephyr Host Stack on QEMU:

```
# A Bluetooth controller needs to be mounted.
# For running with HCI UART, please visit: https://docs.zephyrproject.org/latest/
↪ samples/bluetooth/hci_uart/README.html#bluetooth-hci-uart

python ./autoptsclient-zephyr.py "C:\Users\USER_NAME\Documents\Profile Tuning Suite\
↪ PTS_PROJECT\PTS_PROJECT.pqw6" \
    ~/zephyrproject/build/zephyr/zephyr.elf -i SERVER_IP -l LOCAL_IP
```

Testing Zephyr Host Stack on native posix:

```
# A Bluetooth controller needs to be mounted.
# For running with HCI UART, please visit: https://docs.zephyrproject.org/latest/
↪ samples/bluetooth/hci_uart/README.html#bluetooth-hci-uart

west build -b native_posix zephyr/tests/bluetooth/tester/ -DOVERLAY_CONFIG=overlay-
↪ native.conf
```

(continues on next page)

(continued from previous page)

```
sudo python ./autoptsclient-zephyr.py "C:\Users\USER_NAME\Documents\Profile Tuning\
↳Suite\PTS_PROJECT\PTS_PROJECT.pqw6" \
~/zephyrproject/build/zephyr/zephyr.exe -i SERVER_IP -l LOCAL_IP --hci 0
```

Testing Zephyr combined (controller + host) build on nRF52:

**Note:** If the error “ImportError: No module named pywintypes” appeared after the fresh setup, uninstall and install the pywin32 module:

```
pip install --upgrade --force-reinstall pywin32
```

Run client:

```
python ./autoptsclient-zephyr.py zephyr-master ~/zephyrproject/build/zephyr/zephyr.
↳elf -t /dev/ACM0 \
-b nrf52 -l 192.168.2.1 -i 192.168.2.2
```

```
codecou@:~/auto-pts$ ./autoptsclient-zephyr.py zephyr-master ~/zephyrproject/build/zephyr/zephyr.elf
-t /dev/ttyACM0 -b nrf52 -l 192.168.2.1 -i 192.168.2.2
(140092026955280) Starting PTS 192.168.2.2 ...
(140092026955280) OK
1/629 DIS DIS/SR/SD/BV-01-C PASS 23.477
2/629 DIS DIS/SR/DEC/BV-01-C PASS 22.659
```

At the first run, when Windows asks, enable connection through firewall:

## Troubleshooting

- “After running one test, I need to restart my Windows virtual machine to run another, because of fail verdict from APICOM in PTS logs.”

It means your virtual machine has not enough processor cores or memory. Try to add more in settings. Note that a host with 4 CPUs could be not enough with VirtualBox as hypervisor. In this case, choose rather VMWare Workstation.

- “I cannot start autoptsserver-zephyr.py. I always got error:”

```
codecou@DESKTOP-5SFTBGB MINGW64 ~/auto-pts (master)
$ python ./autoptsserver.py
Local IP address: ('10.0.2.15', 'fe80::ccb2:6ca1:6368:342a') DNS 'home'
Local IP address: ('192.168.2.2', 'fe80::fd12:15d5:2ddb:9147') DNS None
Starting PTS ...

```

One or more of the following steps should help:

- Close all PTS Windows.
- Replug PTS bluetooth dongle.
- Delete temporary workspace. You will find it in auto-pts-code/workspaces/zephyr/zephyr-master/ as temp\_zephyr-master. Be careful, do not remove the original one zephyr-master.pqw6.
- Restart Windows virtual machine.

## 8.4 Documentation Generation

These instructions will walk you through generating the Zephyr Project’s documentation on your local system using the same documentation sources as we use to create the online documentation found at <https://docs.zephyrproject.org>

### 8.4.1 Documentation overview

Zephyr Project content is written using the reStructuredText markup language (.rst file extension) with Sphinx extensions, and processed using Sphinx to create a formatted stand-alone website. Developers can view this content either in its raw form as .rst markup files, or you can generate the HTML content and view it with a web browser directly on your workstation. This same .rst content is also fed into the Zephyr Project’s public website documentation area (with a different theme applied).

You can read details about [reStructuredText](#), and [Sphinx](#) from their respective websites.

The project’s documentation contains the following items:

- ReStructuredText source files used to generate documentation found at the <https://docs.zephyrproject.org> website. Most of the reStructuredText sources are found in the /doc directory,

but others are stored within the code source tree near their specific component (such as `/samples` and `/boards`)

- Doxygen-generated material used to create all API-specific documents also found at <https://docs.zephyrproject.org>
- Script-generated material for kernel configuration options based on Kconfig files found in the source code tree

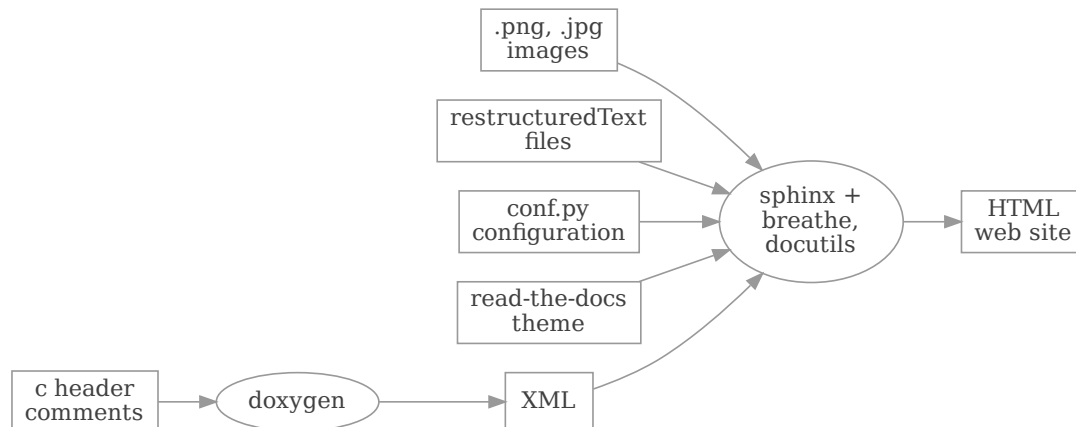

Fig. 4: Schematic of the documentation build process

The reStructuredText files are processed by the Sphinx documentation system, and make use of the breathe extension for including the doxygen-generated API material. Additional tools are required to generate the documentation locally, as described in the following sections.

### 8.4.2 Installing the documentation processors

Our documentation processing has been tested to run with:

- Doxygen version 1.8.13
- Graphviz 2.43
- Latexmk version 4.56
- All Python dependencies listed in the repository file `scripts/requirements-doc.txt`

In order to install the documentation tools, first install Zephyr as described in [Getting Started Guide](#). Then install additional tools that are only required to generate the documentation, as described below:

Linux

On Ubuntu Linux:

```
sudo apt-get install --no-install-recommends doxygen graphviz librsvg2-bin \
texlive-latex-base texlive-latex-extra latexmk texlive-fonts-recommended
```

On Fedora Linux:

```
sudo dnf install doxygen graphviz texlive-latex latexmk \
texlive-collection-fontsrecommended librsvg2-tools
```

On Clear Linux:

```
sudo swupd bundle-add texlive graphviz
```

On Arch Linux:

```
sudo pacman -S graphviz doxygen librsvg texlive-core texlive-bin
```

macOS

Use brew and tlmgr to install the tools:

```
brew install doxygen graphviz mactex librsvg
tlmgr install latexmk
tlmgr install collection-fontsrecommended
```

Windows

Open a cmd.exe window as **Administrator** and run the following command:

```
choco install doxygen.install graphviz strawberryperl miktex rsvg-convert
```

---

**Note:** On Windows, the Sphinx executable `sphinx-build.exe` is placed in the Scripts folder of your Python installation path. Depending on how you have installed Python, you might need to add this folder to your PATH environment variable. Follow the instructions in [Windows Python Path](#) to add those if needed.

---

### 8.4.3 Documentation presentation theme

Sphinx supports easy customization of the generated documentation appearance through the use of themes. Replace the theme files and do another `make htmldocs` and the output layout and style is changed. The read-the-docs theme is installed as part of the [Get Zephyr and install Python dependencies](#) step you took in the getting started guide.

### 8.4.4 Running the documentation processors

The `/doc` directory in your cloned copy of the Zephyr project git repo has all the `.rst` source files, extra tools, and Makefile for generating a local copy of the Zephyr project's technical documentation. Assuming the local Zephyr project copy is in a folder `zephyr` in your home folder, here are the commands to generate the html content locally:

```
# On Linux/macOS
cd ~/zephyr/doc
# On Windows
cd %userprofile%\zephyr\doc

# Use cmake to configure a Ninja-based build system:
cmake -GNinja -B_build .

# Enter the build directory
cd _build

# To generate HTML output, run ninja on the generated build system:
ninja html
# If you modify or add .rst files, run ninja again:
ninja html
```

(continues on next page)

(continued from previous page)

```
# To generate PDF output, run ninja on the generated build system:
ninja pdf
```

**Warning:** The documentation build system creates copies in the build directory of every .rst file used to generate the documentation, along with dependencies referenced by those .rst files.

This means that Sphinx warnings and errors refer to the **copies**, and **not the version-controlled original files in Zephyr**. Be careful to make sure you don't accidentally edit the copy of the file in an error message, as these changes will not be saved.

Depending on your development system, it will take up to 15 minutes to collect and generate the HTML content. When done, you can view the HTML output with your browser started at `doc/_build/html/index.html` and if generated, the PDF file is available at `doc/_build/pdf/zephyr.pdf`.

If you want to build the documentation from scratch just delete the contents of the build folder and run `cmake` and then `ninja` again.

---

**Note:** If you add or remove a file from the documentation, you need to re-run CMake.

---

On Unix platforms a convenience [Makefile](#) at the `doc` folder of the Zephyr repository can be used to build the documentation directly from there:

```
cd ~/zephyr/doc

# To generate HTML output
make html

# To generate PDF output
make pdf
```

### 8.4.5 Filtering expected warnings

There are some known issues with Sphinx/Breathe that generate Sphinx warnings even though the input is valid C code. While these issues are being considered for fixing we have created a Sphinx extension that allows to filter them out based on a set of regular expressions. The extension is named `zephyr_warnings_filter` and it is located at `doc/_extensions/zephyr/warnings_filter.py`. The warnings to be filtered out can be added to the `doc/known-warnings.txt` file.

The most common warning reported by Sphinx/Breathe is related to duplicate C declarations. This warning may be caused by different Sphinx/Breathe issues:

- Multiple declarations of the same object are not supported
- Different objects (e.g. a struct and a function) can not share the same name
- Nested elements (e.g. in a struct or union) can not share the same name

### 8.4.6 Developer-mode Document Building

When making and testing major changes to the documentation, we provide an option to temporarily stub-out the auto-generated Devicetree bindings documentation so the doc build process runs faster.

To enable this mode, set the following option when invoking `cmake`:

```
-DDT_TURBO_MODE=1
```

or invoke make with the following target:

```
cd ~/zephyr

# To generate HTML output without detailed Kconfig
make html-fast
```

## 8.5 Coccinelle

Coccinelle is a tool for pattern matching and text transformation that has many uses in kernel development, including the application of complex, tree-wide patches and detection of problematic programming patterns.

---

**Note:** Linux and macOS development environments are supported, but not Windows.

---

### 8.5.1 Getting Coccinelle

The semantic patches included in the kernel use features and options which are provided by Coccinelle version 1.0.0-rc11 and above. Using earlier versions will fail as the option names used by the Coccinelle files and `coccicheck` have been updated.

Coccinelle is available through the package manager of many distributions, e.g. :

- Debian
- Fedora
- Ubuntu
- OpenSUSE
- Arch Linux
- NetBSD
- FreeBSD

Some distribution packages are obsolete and it is recommended to use the latest version released from the Coccinelle homepage at <http://coccinelle.lip6.fr/>

Or from Github at:

<https://github.com/coccinelle/coccinelle>

Once you have it, run the following commands:

```
./autogen
./configure
make
```

as a regular user, and install it with:

```
sudo make install
```

More detailed installation instructions to build from source can be found at:

<https://github.com/coccinelle/coccinelle/blob/master/install.txt>

### 8.5.2 Supplemental documentation

For Semantic Patch Language(SmPL) grammar documentation refer to:

<http://coccinelle.lip6.fr/documentation.php>

### 8.5.3 Using Coccinelle on Zephyr

coccicheck checker is the front-end to the Coccinelle infrastructure and has various modes:

Four basic modes are defined: patch, report, context, and org. The mode to use is specified by setting `--mode=<mode>` or `-m=<mode>`.

- patch proposes a fix, when possible.
- report generates a list in the following format: `file:line:column-column: message`
- context highlights lines of interest and their context in a diff-like style. Lines of interest are indicated with `-`.
- org generates a report in the Org mode format of Emacs.

Note that not all semantic patches implement all modes. For easy use of Coccinelle, the default mode is report.

Two other modes provide some common combinations of these modes.

- chain tries the previous modes in the order above until one succeeds.
- rep+ctxt runs successively the report mode and the context mode. It should be used with the C option (described later) which checks the code on a file basis.

### 8.5.4 Examples

To make a report for every semantic patch, run the following command:

```
./scripts/coccicheck --mode=report
```

To produce patches, run:

```
./scripts/coccicheck --mode=patch
```

The coccicheck target applies every semantic patch available in the sub-directories of `scripts/coccinelle` to the entire source code tree.

For each semantic patch, a commit message is proposed. It gives a description of the problem being checked by the semantic patch, and includes a reference to Coccinelle.

As any static code analyzer, Coccinelle produces false positives. Thus, reports must be carefully checked, and patches reviewed.

To enable verbose messages set `--verbose=1` option, for example:

```
./scripts/coccicheck --mode=report --verbose=1
```

### 8.5.5 Coccinelle parallelization

By default, coccicheck tries to run as parallel as possible. To change the parallelism, set the `--jobs=<number>` option. For example, to run across 4 CPUs:

```
./scripts/coccicheck --mode=report --jobs=4
```

As of Coccinelle 1.0.2 Coccinelle uses Ocaml parmap for parallelization, if support for this is detected you will benefit from parmap parallelization.

When parmap is enabled `coccicheck` will enable dynamic load balancing by using `--chunksize 1` argument, this ensures we keep feeding threads with work one by one, so that we avoid the situation where most work gets done by only a few threads. With dynamic load balancing, if a thread finishes early we keep feeding it more work.

When parmap is enabled, if an error occurs in Coccinelle, this error value is propagated back, the return value of the `coccicheck` command captures this return value.

### 8.5.6 Using Coccinelle with a single semantic patch

The option `--cocci` can be used to check a single semantic patch. In that case, the variable must be initialized with the name of the semantic patch to apply.

For instance:

```
./scripts/coccicheck --mode=report --cocci=<example.cocci>
```

or:

```
./scripts/coccicheck --mode=report --cocci=./path/to/<example.cocci>
```

### 8.5.7 Controlling which files are processed by Coccinelle

By default the entire source tree is checked.

To apply Coccinelle to a specific directory, pass the path of specific directory as an argument.

For example, to check `drivers/usb/` one may write:

```
./scripts/coccicheck --mode=patch drivers/usb/
```

The report mode is the default. You can select another one with the `--mode=<mode>` option explained above.

### 8.5.8 Debugging Coccinelle SmPL patches

Using `coccicheck` is best as it provides in the `spatch` command line include options matching the options used when we compile the kernel. You can learn what these options are by using verbose option, you could then manually run Coccinelle with debug options added.

Alternatively you can debug running Coccinelle against SmPL patches by asking for `stderr` to be redirected to `stderr`, by default `stderr` is redirected to `/dev/null`, if you'd like to capture `stderr` you can specify the `--debug=file.err` option to `coccicheck`. For instance:

```
rm -f cocci.err
./scripts/coccicheck --mode=patch --debug=cocci.err
cat cocci.err
```

Debugging support is only supported when using Coccinelle `>= 1.0.2`.

### 8.5.9 Additional Flags

Additional flags can be passed to `spatch` through the `SPFLAGS` variable. This works as Coccinelle respects the last flags given to it when options are in conflict.

```
./scripts/coccicheck --sp-flag="--use-glimpse"
```

Coccinelle supports idutils as well but requires coccinelle  $\geq 1.0.6$ . When no ID file is specified coccinelle assumes your ID database file is in the file `.id-utils.index` on the top level of the kernel, coccinelle carries a script `scripts/idutils_index.sh` which creates the database with:

```
mkid -i C --output .id-utils.index
```

If you have another database filename you can also just symlink with this name.

```
./scripts/coccicheck --sp-flag="--use-idutils"
```

Alternatively you can specify the database filename explicitly, for instance:

```
./scripts/coccicheck --sp-flag="--use-idutils /full-path/to/ID"
```

Sometimes coccinelle doesn't recognize or parse complex macro variables due to insufficient definition. Therefore, to make it parsable we explicitly provide the prototype of the complex macro using the `---macro-file-builtins <headerfile.h> flag`.

The `<headerfile.h>` should contain the complete prototype of the complex macro from which spatch engine can extract the type information required during transformation.

For example:

`Z_SYSCALL_HANDLER` is not recognized by coccinelle. Therefore, we put its prototype in a header file, say for example `mymacros.h`.

```
$ cat mymacros.h
#define Z_SYSCALL_HANDLER int xxx
```

Now we pass the header file `mymacros.h` during transformation:

```
./scripts/coccicheck --sp-flag="---macro-file-builtins mymacros.h"
```

See `spatch --help` to learn more about spatch options.

Note that the `--use-glimpse` and `--use-idutils` options require external tools for indexing the code. None of them is thus active by default. However, by indexing the code with one of these tools, and according to the cocci file used, spatch could proceed the entire code base more quickly.

### 8.5.10 SmPL patch specific options

SmPL patches can have their own requirements for options passed to Coccinelle. SmPL patch specific options can be provided by providing them at the top of the SmPL patch, for instance:

```
// Options: --no-includes --include-headers
```

### 8.5.11 Proposing new semantic patches

New semantic patches can be proposed and submitted by kernel developers. For sake of clarity, they should be organized in the sub-directories of `scripts/coccinelle/`.

The cocci script should have the following properties:

- The script **must** have report mode.
- The first few lines should state the purpose of the script using `///` comments. Usually, this message would be used as the commit log when proposing a patch based on the script.

### Example

```
/// Use ARRAY_SIZE instead of dividing sizeof array with sizeof an element
```

- A more detailed information about the script with exceptional cases or false positives (if any) can be listed using `/// comments.`

### Example

```
/// This makes an effort to find cases where ARRAY_SIZE can be used such as  
/// where there is a division of sizeof the array by the sizeof its first  
/// element or by any indexed element or the element type. It replaces the  
/// division of the two sizeofs by ARRAY_SIZE.
```

- Confidence: It is a property defined to specify the accuracy level of the script. It can be either High, Moderate or Low depending upon the number of false positives observed.

### Example

```
// Confidence: High
```

- Virtual rules: These are required to support the various modes framed in the script. The virtual rule specified in the script should have the corresponding mode handling rule.

### Example

```
virtual context  
  
@depends on context@  
type T;  
T[] E;  
@@  
(  
* (sizeof(E)/sizeof(*E))  
|  
* (sizeof(E)/sizeof(E[...]))  
|  
* (sizeof(E)/sizeof(T))  
)
```

## 8.5.12 Detailed description of the report mode

report generates a list in the following format:

```
file:line:column-column: message
```

### Example

Running:

```
./scripts/coccicheck --mode=report --cocci=scripts/coccinelle/array_size.cocci
```

will execute the following part of the SmPL script:

```
<smpl>

@r depends on (org || report)@
type T;
T[] E;
position p;
@@
(
  (sizeof(E)@p /sizeof(*E))
  |

)

@script:python depends on report@
p << r.p;
@@

msg="WARNING: Use ARRAY_SIZE"
cocci.lib.report.print_report(p[0], msg)

</smpl>
```

This SmPL excerpt generates entries on the standard output, as illustrated below:

```
ext/hal/nxp/mcux/drivers/lpc/fsl_wwdt.c:66:49-50: WARNING: Use ARRAY_SIZE
ext/hal/nxp/mcux/drivers/lpc/fsl_ctimer.c:74:53-54: WARNING: Use ARRAY_SIZE
ext/hal/nxp/mcux/drivers/imx/fsl_dcp.c:944:45-46: WARNING: Use ARRAY_SIZE
```

### 8.5.13 Detailed description of the patch mode

When the patch mode is available, it proposes a fix for each problem identified.

#### Example

Running:

```
./scripts/coccicheck --mode=patch --cocci=scripts/coccinelle/misc/array_size.cocci
```

will execute the following part of the SmPL script:

```
<smpl>

@depends on patch@
type T;
T[] E;

### 8.5.14 Detailed description of the context mode

context highlights lines of interest and their context in a diff-like style.

---

**Note:** The diff-like output generated is NOT an applicable patch. The intent of the context mode is to highlight the important lines (annotated with minus, -) and gives some surrounding context lines around. This output can be used with the diff mode of Emacs to review the code.

---

#### Example

Running:

```
./scripts/coccicheck --mode=context --cocci=scripts/coccinelle/array_size.cocci
```

will execute the following part of the SmPL script:

```

## 8.6 Code And Data Relocation

### 8.6.1 Overview

This feature will allow relocating .text, .rodata, .data, and .bss sections from required files and place them in the required memory region. The memory region and file are given to the [scripts/gen\\_relocate\\_app.py](#) script in the form of a string. This script is always invoked from inside cmake.

This script provides a robust way to re-order the memory contents without actually having to modify the code. In simple terms this script will do the job of `__attribute__((section("name")))` for a bunch of files together.

### 8.6.2 Details

The memory region and file are given to the [scripts/gen\\_relocate\\_app.py](#) script in the form of a string.

An example of such a string is: `SRAM2:/home/xyz/zephyr/samples/hello_world/src/main.c, SRAM1:/home/xyz/zephyr/samples/hello_world/src/main2.c`

This script is invoked with the following parameters: `python3 gen_relocate_app.py -i input_string -o generated_linker -c generated_code`

Kconfig **:kconfig: `CONFIG\_CODE\_DATA\_RELOCATION`** option, when enabled in `prj.conf`, will invoke the script and do the required relocation.

This script also trigger the generation of `linker_relocate.ld` and `code_relocation.c` files. The `linker_relocate.ld` file creates appropriate sections and links the required functions or variables from all the selected files.

---

**Note:** The text section is split into 2 parts in the main linker script. The first section will have some info regarding vector tables and other debug related info. The second section will have the complete text section. This is needed to force the required functions and data variables to the correct locations. This is due to the behavior of the linker. The linker will only link once and hence this text section had to be split to make room for the generated linker script.

---

The `code_relocation.c` file has code that is needed for initializing data sections, and a copy of the text sections (if XIP). Also this contains code needed for bss zeroing and for data copy operations from ROM to required memory type.

**The procedure to invoke this feature is:**

- Enable **:kconfig: `CONFIG\_CODE\_DATA\_RELOCATION`** in the `prj.conf` file

- Inside the `CMakeLists.txt` file in the project, mention all the files that need relocation.

```
zephyr_code_relocate(src/*.c SRAM2)
```

Where the first argument is the file/files and the second argument is the memory where it must be placed.

---

**Note:** The file argument supports limited regular expressions. function `zephyr_code_relocate()` can be called as many times as required. This step has to be performed before the inclusion of `boilerplate.cmake`.

---

## Additional Configurations

This section shows additional configuration options that can be set in `CMakeLists.txt`

- if the memory is SRAM1, SRAM2, CCD, or AON, then place the full object in the sections for example:

```
zephyr_code_relocate(src/file1.c SRAM2)
zephyr_code_relocate(src/file2.c.c SRAM)
```

- if the memory type is appended with `_DATA`, `_TEXT`, `_RODATA` or `_BSS`, only the selected memory is placed in the required memory region. for example:

```
zephyr_code_relocate(src/file1.c SRAM2_DATA)
zephyr_code_relocate(src/file2.c.c SRAM2_TEXT)
```

- Multiple regions can also be appended together such as: `SRAM2_DATA_BSS`. This will place data and bss inside SRAM2.

## Sample

A sample showcasing this feature is provided at `$ZEPHYR_BASE/samples/application_development/code_relocation/`

This is an example of using the code relocation feature.

This example will place `.text`, `.data`, `.bss` from 3 files to various parts in the SRAM using a custom linker file derived from `include/arch/arm/aarch32/cortex_m/scripts/linker.ld`

## 8.7 Cryptography

The crypto section contains information regarding the cryptographic primitives supported by the Zephyr kernel. Use the information to understand the principles behind the operation of the different algorithms and how they were implemented.

The following crypto libraries have been included:

### 8.7.1 TinyCrypt Cryptographic Library

#### Overview

The TinyCrypt Library provides an implementation for targeting constrained devices with a minimal set of standard cryptography primitives, as listed below. To better serve applications targeting constrained devices, TinyCrypt implementations differ from the standard specifications (see the Important Remarks

section for some important differences). Certain cryptographic primitives depend on other primitives, as mentioned in the list below.

Aside from the Important Remarks section below, valuable information on the usage, security and technicalities of each cryptographic primitive are found in the corresponding header file.

- SHA-256:
  - Type of primitive: Hash function.
  - Standard Specification: NIST FIPS PUB 180-4.
  - Requires: –
- HMAC-SHA256:
  - Type of primitive: Message authentication code.
  - Standard Specification: RFC 2104.
  - Requires: SHA-256
- HMAC-PRNG:
  - Type of primitive: Pseudo-random number generator.
  - Standard Specification: NIST SP 800-90A.
  - Requires: SHA-256 and HMAC-SHA256.
- AES-128:
  - Type of primitive: Block cipher.
  - Standard Specification: NIST FIPS PUB 197.
  - Requires: –
- AES-CBC mode:
  - Type of primitive: Encryption mode of operation.
  - Standard Specification: NIST SP 800-38A.
  - Requires: AES-128.
- AES-CTR mode:
  - Type of primitive: Encryption mode of operation.
  - Standard Specification: NIST SP 800-38A.
  - Requires: AES-128.
- AES-CMAC mode:
  - Type of primitive: Message authentication code.
  - Standard Specification: NIST SP 800-38B.
  - Requires: AES-128.
- AES-CCM mode:
  - Type of primitive: Authenticated encryption.
  - Standard Specification: NIST SP 800-38C.
  - Requires: AES-128.
- ECC-DH:
  - Type of primitive: Key exchange.
  - Standard Specification: RFC 6090.
  - Requires: ECC auxiliary functions (ecc.h/c).

- ECC-DSA:
  - Type of primitive: Digital signature.
  - Standard Specification: RFC 6090.
  - Requires: ECC auxiliary functions (ecc.h/c).

### Design Goals

- Minimize the code size of each cryptographic primitive. This means minimize the size of a board-independent implementation, as presented in TinyCrypt. Note that various applications may require further features, optimizations with respect to other metrics and countermeasures for particular threats. These peculiarities would increase the code size and thus are not considered here.
- Minimize the dependencies among the cryptographic primitives. This means that it is unnecessary to build and allocate object code for more primitives than the ones strictly required by the intended application. In other words, one can select and compile only the primitives required by the application.

### Important Remarks

The cryptographic implementations in TinyCrypt library have some limitations. Some of these limitations are inherent to the cryptographic primitives themselves, while others are specific to TinyCrypt. Some of these limitations are discussed in-depth below.

### General Remarks

- TinyCrypt does **not** intend to be fully side-channel resistant. Due to the variety of side-channel attacks, many of them making certain boards vulnerable. In this sense, instead of penalizing all library users with side-channel countermeasures such as increasing the overall code size, TinyCrypt only implements certain generic timing-attack countermeasures.

### Specific Remarks

- SHA-256:
  - The number of bits\_hashed in the state is not checked for overflow. Note however that this will only be a problem if you intend to hash more than  $2^{64}$  bits, which is an extremely large window.
- HMAC:
  - The HMAC verification process is assumed to be performed by the application. This compares the computed tag with some given tag. Note that conventional memory-comparison methods (such as memcmp function) might be vulnerable to timing attacks; thus be sure to use a constant-time memory comparison function (such as compare\_constant\_time function provided in lib/utls.c).
- HMAC-PRNG:
  - Before using HMAC-PRNG, you *must* find an entropy source to produce a seed. PRNGs only stretch the seed into a seemingly random output of arbitrary length. The security of the output is exactly equal to the unpredictability of the seed.
  - NIST SP 800-90A requires three items as seed material in the initialization step: entropy seed, personalization and a nonce (which is not implemented). TinyCrypt requires the personalization byte array and automatically creates the entropy seed using a mandatory call to the re-seed function.

- AES-128:
  - The current implementation does not support other key-lengths (such as 256 bits). Note that if you need AES-256, it doesn't sound as though your application is running in a constrained environment. AES-256 requires keys twice the size as for AES-128, and the key schedule is 40% larger.
- CTR mode:
  - The AES-CTR mode limits the size of a data message they encrypt to  $2^{32}$  blocks. If you need to encrypt larger data sets, your application would need to replace the key after  $2^{32}$  block encryptions.
- CBC mode:
  - TinyCrypt CBC decryption assumes that the iv and the ciphertext are contiguous (as produced by TinyCrypt CBC encryption). This allows for a very efficient decryption algorithm that would not otherwise be possible.
- CMAC mode:
  - AES128-CMAC mode of operation offers 64 bits of security against collision attacks. Note however that an external attacker cannot generate the tags him/herself without knowing the MAC key. In this sense, to attack the collision property of AES128-CMAC, an external attacker would need the cooperation of the legal user to produce an exponentially high number of tags (e.g.  $2^{64}$ ) to finally be able to look for collisions and benefit from them. As an extra precaution, the current implementation allows to at most  $2^{48}$  calls to `tc_cmac_update` function before re-calling `tc_cmac_setup` (allowing a new key to be set), as suggested in Appendix B of SP 800-38B.
- CCM mode:
  - There are a few tradeoffs for the selection of the parameters of CCM mode. In special, there is a tradeoff between the maximum number of invocations of CCM under a given key and the maximum payload length for those invocations. Both things are related to the parameter 'q' of CCM mode. The maximum number of invocations of CCM under a given key is determined by the nonce size, which is: 15-q bytes. The maximum payload length for those invocations is defined as  $2^{(8q)}$  bytes.

To achieve minimal code size, TinyCrypt CCM implementation fixes  $q = 2$ , which is a quite reasonable choice for constrained applications. The implications of this choice are:

The nonce size is: 13 bytes.

The maximum payload length is:  $2^{16}$  bytes = 65 KB.

The mac size parameter is an important parameter to estimate the security against collision attacks (that aim at finding different messages that produce the same authentication tag). TinyCrypt CCM implementation accepts any even integer between 4 and 16, as suggested in SP 800-38C.
  - TinyCrypt CCM implementation accepts associated data of any length between 0 and  $(2^{16} - 2^8) = 65280$  bytes.
  - TinyCrypt CCM implementation accepts:
    - \* Both non-empty payload and associated data (it encrypts and authenticates the payload and only authenticates the associated data);
    - \* Non-empty payload and empty associated data (it encrypts and authenticates the payload);
    - \* Non-empty associated data and empty payload (it degenerates to an authentication-only mode on the associated data).
  - RFC-3610, which also specifies CCM, presents a few relevant security suggestions, such as: it is recommended for most applications to use a mac size greater than 8. Besides, it is

emphasized that the usage of the same nonce for two different messages which are encrypted with the same key obviously destroys the security properties of CCM mode.

- ECC-DH and ECC-DSA:
  - TinyCrypt ECC implementation is based on nano-ecc (see <https://github.com/iSECPartners/nano-ecc>) which in turn is based on micro-ecc (see <https://github.com/kmackay/micro-ecc>). In the original nano and micro-ecc documentation, there is an important remark about the way integers are represented:  
“Integer representation: To reduce code size, all large integers are represented using little-endian words - so the least significant word is first. You can use the ‘ecc\_bytes2native()’ and ‘ecc\_native2bytes()’ functions to convert between the native integer representation and the standardized octet representation.”

## Examples of Applications

It is possible to do useful cryptography with only the given small set of primitives. With this list of primitives it becomes feasible to support a range of cryptography usages:

- Measurement of code, data structures, and other digital artifacts (SHA256);
- Generate commitments (SHA256);
- Construct keys (HMAC-SHA256);
- Extract entropy from strings containing some randomness (HMAC-SHA256);
- Construct random mappings (HMAC-SHA256);
- Construct nonces and challenges (HMAC-PRNG);
- Authenticate using a shared secret (HMAC-SHA256);
- Create an authenticated, replay-protected session (HMAC-SHA256 + HMAC-PRNG);
- Authenticated encryption (AES-128 + AES-CCM);
- Key-exchange (EC-DH);
- Digital signature (EC-DSA);

## Test Vectors

The library provides a test program for each cryptographic primitive (see ‘test’ folder). Besides illustrating how to use the primitives, these tests evaluate the correctness of the implementations by checking the results against well-known publicly validated test vectors.

For the case of the HMAC-PRNG, due to the necessity of performing an extensive battery test to produce meaningful conclusions, we suggest the user to evaluate the unpredictability of the implementation by using the NIST Statistical Test Suite (see References).

For the case of the EC-DH and EC-DSA implementations, most of the test vectors were obtained from the site of the NIST Cryptographic Algorithm Validation Program (CAVP), see References.

## 8.8 Flashing and Hardware Debugging

### 8.8.1 Flash & Debug Host Tools

This guide describes the software tools you can run on your host workstation to flash and debug Zephyr applications.

Zephyr's `west` tool has built-in support for all of these in its `flash`, `debug`, `debugserver`, and `attach` commands, provided your board hardware supports them and your Zephyr board directory's `board.cmake` file declares that support properly. See [Building, Flashing and Debugging](#) for more information on these commands.

#### SAM Boot Assistant (SAM-BA)

Atmel SAM Boot Assistant (Atmel SAM-BA) allows In-System Programming (ISP) from USB or UART host without any external programming interface. Zephyr allows users to develop and program boards with SAM-BA support using `west`. Zephyr supports devices with/without ROM bootloader and both extensions from Arduino and Adafruit. Full support was introduced in Zephyr SDK 0.12.0.

The typical command to flash the board is:

```
west flash [ -r bossac ] [ -p /dev/ttyX ]
```

Flash configuration for devices:

With ROM bootloader

These devices don't need any special configuration. After building your application, just run `west flash` to flash the board.

Without ROM bootloader

For these devices, the user should:

1. Define flash partitions required to accommodate the bootloader and application image; see [Flash map](#) for details.
2. Have board `.defconfig` file with the `:kconfig:CONFIG_USE_DT_CODE_PARTITION` Kconfig option set to `y` to instruct the build system to use these partitions for code relocation. This option can also be set in `prj.conf` or any other Kconfig fragment.
3. Build and flash the SAM-BA bootloader on the device.

With compatible SAM-BA bootloader

For these devices, the user should:

1. Define flash partitions required to accommodate the bootloader and application image; see [Flash map](#) for details.

2. Have board .defconfig file with the `:kconfig:CONFIG_BOOTLOADER_BOSSA` Kconfig option set to y. This will automatically select the `:kconfig:CONFIG_USE_DT_CODE_PARTITION` Kconfig option which instruct the build system to use these partitions for code relocation. The board .defconfig file should have `:kconfig:CONFIG_BOOTLOADER_BOSSA_ARDUINO`, `:kconfig:CONFIG_BOOTLOADER_BOSSA_ADAFRUIT_UF2` or the `:kconfig:CONFIG_BOOTLOADER_BOSSA_LEGACY` Kconfig option set to y to select the right compatible SAM-BA bootloader mode. These options can also be set in `prj.conf` or any other Kconfig fragment.
3. Build and flash the SAM-BA bootloader on the device.

---

**Note:** The `:kconfig:CONFIG_BOOTLOADER_BOSSA_LEGACY` Kconfig option should be used as last resource. Try configure first with Devices without ROM bootloader.

---

**Typical flash layout and configuration** For bootloaders that reside on flash, the devicetree partition layout is mandatory. For devices that have a ROM bootloader, they are mandatory when the application uses a storage or other non-application partition. In this special case, the boot partition should be omitted and `code_partition` should start from offset 0. It is necessary to define the partitions with sizes that avoid overlaps, always.

A typical flash layout for devices without a ROM bootloader is:

```
/ {
    chosen {
        zephyr,code-partition = &code_partition;
    };
};

&flash0 {
    partitions {
        compatible = "fixed-partitions";
        #address-cells = <1>;
        #size-cells = <1>;

        boot_partition: partition@0 {
            label = "sam-ba";
            reg = <0x00000000 0x2000>;
            read-only;
        };

        code_partition: partition@2000 {
            label = "code";
            reg = <0x2000 0x3a000>;
            read-only;
        };

        /*
         * The final 16 KiB is reserved for the application.
         * Storage partition will be used by FCB/LittleFS/NVS
         * if enabled.
         */
        storage_partition: partition@3c000 {
            label = "storage";
            reg = <0x0003c000 0x00004000>;
        };
    };
};
```

A typical flash layout for devices with a ROM bootloader and storage partition is:

```
/ {
    chosen {
        zephyr,code-partition = &code_partition;
    };
};

&flash0 {
    partitions {
        compatible = "fixed-partitions";
        #address-cells = <1>;
        #size-cells = <1>;

        code_partition: partition@0 {
            label = "code";
            reg = <0x0 0xF0000>;
            read-only;
        };

        /*
         * The final 64 KiB is reserved for the application.
         * Storage partition will be used by FCB/LittleFS/NVS
         * if enabled.
         */
        storage_partition: partition@F0000 {
            label = "storage";
            reg = <0x000F0000 0x00100000>;
        };
    };
};
```

**Enabling SAM-BA runner** In order to instruct Zephyr west tool to use the SAM-BA bootloader the `board.cmake` file must have `include(${ZEPHYR_BASE}/boards/common/bossac.board.cmake)` entry. Note that Zephyr tool accept more entries to define multiple runners. By default, the first one will be selected when using `west flash` command. The remaining options are available passing the runner option, for instance `west flash -r bossac`.

More implementation details can be found in the boards documentation. As a quick reference, see these three board documentation pages:

- `sam4e_xpro` (ROM bootloader)
- `adafruit_feather_m0_basic_proto` (Adafruit UF2 bootloader)
- `arduino_nano_33_iot` (Arduino bootloader)
- `arduino_nano_33_ble` (Arduino legacy bootloader)

## J-Link Debug Host Tools

Segger provides a suite of debug host tools for Linux, macOS, and Windows operating systems:

- J-Link GDB Server: GDB remote debugging
- J-Link Commander: Command-line control and flash programming
- RTT Viewer: RTT terminal input and output
- SystemView: Real-time event visualization and recording

These debug host tools are compatible with the following debug probes:

- [LPC-Link2 J-Link Onboard Debug Probe](#)
- [OpenSDA J-Link Onboard Debug Probe](#)
- [J-Link External Debug Probe](#)
- [ST-LINK/V2-1 Onboard Debug Probe](#)

Check if your SoC is listed in [J-Link Supported Devices](#).

Download and install the [J-Link Software and Documentation Pack](#) to get the J-Link GDB Server and Commander, and to install the associated USB device drivers. RTT Viewer and SystemView can be downloaded separately, but are not required.

Note that the J-Link GDB server does not yet support Zephyr RTOS-awareness.

### OpenOCD Debug Host Tools

OpenOCD is a community open source project that provides GDB remote debugging and flash programming support for a wide range of SoCs. A fork that adds Zephyr RTOS-awareness is included in the Zephyr SDK; otherwise see [Getting OpenOCD](#) for options to download OpenOCD from official repositories.

These debug host tools are compatible with the following debug probes:

- [OpenSDA DAPLink Onboard Debug Probe](#)
- [J-Link External Debug Probe](#)
- [ST-LINK/V2-1 Onboard Debug Probe](#)

Check if your SoC is listed in [OpenOCD Supported Devices](#).

---

**Note:** On Linux, openocd is available through the [Zephyr SDK](#). Windows users should use the following steps to install openocd:

- Download openocd for Windows from here: [OpenOCD Windows](#)
  - Copy bin and share dirs to C:\Program Files\OpenOCD\
  - Add C:\Program Files\OpenOCD\bin to 'PATH' environment variable
- 

### pyOCD Debug Host Tools

pyOCD is an open source project from Arm that provides GDB remote debugging and flash programming support for Arm Cortex-M SoCs. It is distributed on PyPi and installed when you complete the [Get Zephyr and install Python dependencies](#) step in the Getting Started Guide. pyOCD includes support for Zephyr RTOS-awareness.

These debug host tools are compatible with the following debug probes:

- [OpenSDA DAPLink Onboard Debug Probe](#)
- [ST-LINK/V2-1 Onboard Debug Probe](#)

Check if your SoC is listed in [pyOCD Supported Devices](#).

## 8.8.2 Debug Probes

A *debug probe* is special hardware which allows you to control execution of a Zephyr application running on a separate board. Debug probes usually allow reading and writing registers and memory, and support breakpoint debugging of the Zephyr application on your host workstation using tools like GDB. They may also support other debug software and more advanced features such as [tracing program execution](#). For details on the related host software supported by Zephyr, see [Flash & Debug Host Tools](#).

Debug probes are usually connected to your host workstation via USB; they are sometimes also accessible via an IP network or other means. They usually connect to the device running Zephyr using the JTAG or SWD protocols. Debug probes are either separate hardware devices or circuitry integrated into the same board which runs Zephyr.

Many supported boards in Zephyr include a second microcontroller that serves as an onboard debug probe, usb-to-serial adapter, and sometimes a drag-and-drop flash programmer. This eliminates the need to purchase an external debug probe and provides a variety of debug host tool options.

Several hardware vendors have their own branded onboard debug probe implementations: NXP LPC boards have [LPC-Link2](#), NXP Kinetis (former Freescale) boards have [OpenSDA](#), and ST boards have [ST-LINK](#). Each onboard debug probe microcontroller can support one or more types of firmware that communicate with their respective debug host tools. For example, an OpenSDA microcontroller can be programmed with DAPLink firmware to communicate with pyOCD or OpenOCD debug host tools, or with J-Link firmware to communicate with J-Link debug host tools.

Debug Probes & Host Tools Compatibility Chart		Host Tools		
		J-Link Debug	OpenOCD	pyOCD
Debug Probes	LPC-Link2 J-Link	✓		
	OpenSDA DAPLink		✓	✓
	OpenSDA J-Link	✓		
	J-Link External	✓	✓	
	ST-LINK/V2-1	✓	✓	some STM32 boards

Some supported boards in Zephyr do not include an onboard debug probe and therefore require an external debug probe. In addition, boards that do include an onboard debug probe often also have an SWD or JTAG header to enable the use of an external debug probe instead. One reason this may be useful is that the onboard debug probe may have limitations, such as lack of support for advanced debuggers or high-speed tracing. You may need to adjust jumpers to prevent the onboard debug probe from interfering with the external debug probe.

### LPC-Link2 J-Link Onboard Debug Probe

The LPC-Link2 J-Link is an onboard debug probe and usb-to-serial adapter supported on many NXP LPC and i.MX RT development boards.

This debug probe is compatible with the following debug host tools:

- [J-Link Debug Host Tools](#)

This probe is realized by programming the LPC-Link2 microcontroller with J-Link LPC-Link2 firmware. Download and install [LPCScript](#) to get the firmware and programming scripts.

---

**Note:** Verify the firmware supports your board by visiting [Firmware for LPCXpresso](#)

---

1. Put the LPC-Link2 microcontroller into DFU boot mode by attaching the DFU jumper, then powering up the board.

2. Run the `program_JLINK` script.
3. Remove the DFU jumper and power cycle the board.

### OpenSDA DAPLink Onboard Debug Probe

The OpenSDA DAPLink is an onboard debug probe and usb-to-serial adapter supported on many NXP Kinetis and i.MX RT development boards. It also includes drag-and-drop flash programming support.

This debug probe is compatible with the following debug host tools:

- [pyOCD Debug Host Tools](#)
- [OpenOCD Debug Host Tools](#)

This probe is realized by programming the OpenSDA microcontroller with DAPLink OpenSDA firmware. NXP provides [OpenSDA DAPLink Board-Specific Firmwares](#).

Install the debug host tools before you program the firmware.

As with all OpenSDA debug probes, the steps for programming the firmware are:

1. Put the OpenSDA microcontroller into bootloader mode by holding the reset button while you power on the board. Note that “bootloader mode” in this context applies to the OpenSDA microcontroller itself, not the target microcontroller of your Zephyr application.
2. After you power on the board, release the reset button. A USB mass storage device called **BOOT-LOADER** or **MAINTENANCE** will enumerate.
3. Copy the OpenSDA firmware binary to the USB mass storage device.
4. Power cycle the board, this time without holding the reset button. You should see three USB devices enumerate: a CDC device (serial port), a HID device (debug port), and a mass storage device (drag-and-drop flash programming).

### OpenSDA J-Link Onboard Debug Probe

The OpenSDA J-Link is an onboard debug probe and usb-to-serial adapter supported on many NXP Kinetis and i.MX RT development boards.

This debug probe is compatible with the following debug host tools:

- [J-Link Debug Host Tools](#)

This probe is realized by programming the OpenSDA microcontroller with J-Link OpenSDA firmware. Segger provides [OpenSDA J-Link Generic Firmwares](#) and [OpenSDA J-Link Board-Specific Firmwares](#), where the latter is generally recommended when available. Board-specific firmwares are required for i.MX RT boards to support their external flash memories, whereas generic firmwares are compatible with all Kinetis boards.

Install the debug host tools before you program the firmware.

As with all OpenSDA debug probes, the steps for programming the firmware are:

1. Put the OpenSDA microcontroller into bootloader mode by holding the reset button while you power on the board. Note that “bootloader mode” in this context applies to the OpenSDA microcontroller itself, not the target microcontroller of your Zephyr application.
2. After you power on the board, release the reset button. A USB mass storage device called **BOOT-LOADER** or **MAINTENANCE** will enumerate.
3. Copy the OpenSDA firmware binary to the USB mass storage device.
4. Power cycle the board, this time without holding the reset button. You should see two USB devices enumerate: a CDC device (serial port) and a vendor-specific device (debug port).

## J-Link External Debug Probe

Segger J-Link is a family of external debug probes, including J-Link EDU, J-Link PLUS, J-Link ULTRA+, and J-Link PRO, that support a large number of devices from different hardware architectures and vendors.

This debug probe is compatible with the following debug host tools:

- [J-Link Debug Host Tools](#)
- [OpenOCD Debug Host Tools](#)

Install the debug host tools before you program the firmware.

## ST-LINK/V2-1 Onboard Debug Probe

ST-LINK/V2-1 is a serial and debug adapter built into all Nucleo and Discovery boards. It provides a bridge between your computer (or other USB host) and the embedded target processor, which can be used for debugging, flash programming, and serial communication, all over a simple USB cable.

It is compatible with the following host debug tools:

- [OpenOCD Debug Host Tools](#)
- [J-Link Debug Host Tools](#)

For some STM32 based boards, it is also compatible with:

- [pyOCD Debug Host Tools](#)

While it works out of the box with OpenOCD, it requires some flashing to work with J-Link. To do this, SEGGER offers a firmware upgrading the ST-LINK/V2-1 on board on the Nucleo and Discovery boards. This firmware makes the ST-LINK/V2-1 compatible with J-LinkOB, allowing users to take advantage of most J-Link features like the ultra fast flash download and debugging speed or the free-to-use GDBServer.

More informations about upgrading ST-LINK/V2-1 to JLink or restore ST-Link/V2-1 firmware please visit: [Segger over ST-Link](#)

## Flash and debug with ST-Link Using OpenOCD

OpenOCD is available by default on ST-Link and configured as the default flash and debug tool. Flash and debug can be done as follows:

```
# From the root of the zephyr repository
west build -b None samples/hello_world
west flash
```

```
# From the root of the zephyr repository
west build -b None samples/hello_world
west debug
```

### Using Segger J-Link

Once STLink is flashed with SEGGER FW and J-Link GDB server is installed on your host computer, you can flash and debug as follows:

Use CMake with `-DBOARD_FLASH_RUNNER=jlink` to change the default OpenOCD runner to J-Link. Alternatively, you might add the following line to your application `CMakeList.txt` file.

```
set(BOARD_FLASH_RUNNER jlink)
```

If you use West (Zephyr's meta-tool) you can modify the default runner using the `--runner` (or `-r`) option.

```
west flash --runner jlink
```

To attach a debugger to your board and open up a debug console with jlink.

```
west debug --runner jlink
```

For more information about West and available options, see [West \(Zephyr's meta-tool\)](#).

If you configured your Zephyr application to use Segger RTT console instead, open telnet:

```
$ telnet localhost 19021
Trying ::1...
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
SEGGER J-Link V6.30f - Real time terminal output
J-Link STLink V21 compiled Jun 26 2017 10:35:16 V1.0, SN=773895351
Process: JLinkGDBServerCLExe
Zephyr Shell, Zephyr version: 1.12.99
Type 'help' for a list of available commands
shell>
```

If you get no RTT output you might need to disable other consoles which conflict with the RTT one if they are enabled by default in the particular sample or application you are running, such as disable UART\_CONSOLE in menucon

**Updating or restoring ST-Link firmware** ST-Link firmware can be updated using [STM32CubeProgrammer Tool](#). It is usually useful when facing flashing issues, for instance when using twister's device-testing option.

Once installed, you can update attached board ST-Link firmware with the following command

```
s java -jar ~/STMicroelectronics/STM32Cube/STM32CubeProgrammer/Drivers/
↪FirmwareUpgrade/STLinkUpgrade.jar -sn <board_uid>
```

Where board\_uid can be obtained using twister's generate-hardware-map option. For more information about twister and available options, see [Test Runner \(Twister\)](#).

## 8.9 Debugging and Tracing

### 8.9.1 Thread analyzer

The thread analyzer module enables all the Zephyr options required to track the thread information, e.g. thread stack size usage and other runtime thread runtime statistics.

The analysis is performed on demand when the application calls [thread\\_analyzer\\_run\(\)](#) or [thread\\_analyzer\\_print\(\)](#).

For example, to build the synchronization sample with Thread Analyser enabled, do the following:

```
west build -b qemu_x86 samples/synchronization/ -- -DCONFIG_QEMU_ICOUNT=n -
↪DCONFIG_THREAD_ANALYZER=y \
-DCONFIG_THREAD_ANALYZER_USE_PRINTK=y -DCONFIG_THREAD_ANALYZER_AUTO=y \
-DCONFIG_THREAD_ANALYZER_AUTO_INTERVAL=5
```

When you run the generated application in Qemu, you will get the additional information from Thread Analyzer:

```
thread_a: Hello World from cpu 0 on qemu_x86!
Thread analyze:
  thread_b      : STACK: unused 740 usage 284 / 1024 (27 %); CPU: 0 %
  thread_analyzer : STACK: unused 8 usage 504 / 512 (98 %); CPU: 0 %
  thread_a      : STACK: unused 648 usage 376 / 1024 (36 %); CPU: 98 %
  idle 00       : STACK: unused 204 usage 116 / 320 (36 %); CPU: 0 %
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
Thread analyze:
  thread_b      : STACK: unused 648 usage 376 / 1024 (36 %); CPU: 7 %
  thread_analyzer : STACK: unused 8 usage 504 / 512 (98 %); CPU: 0 %
  thread_a      : STACK: unused 648 usage 376 / 1024 (36 %); CPU: 9 %
  idle 00       : STACK: unused 204 usage 116 / 320 (36 %); CPU: 82 %
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
Thread analyze:
  thread_b      : STACK: unused 648 usage 376 / 1024 (36 %); CPU: 7 %
  thread_analyzer : STACK: unused 8 usage 504 / 512 (98 %); CPU: 0 %
  thread_a      : STACK: unused 648 usage 376 / 1024 (36 %); CPU: 8 %
  idle 00       : STACK: unused 204 usage 116 / 320 (36 %); CPU: 83 %
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
```

## Configuration

Configure this module using the following options.

- `THREAD_ANALYZER`: enable the module.
- `THREAD_ANALYZER_USE_PRINTK`: use `printk` for thread statistics.
- `THREAD_ANALYZER_USE_LOG`: use the logger for thread statistics.
- `THREAD_ANALYZER_AUTO`: run the thread analyzer automatically. You do not need to add any code to the application when using this option.
- `THREAD_ANALYZER_AUTO_INTERVAL`: the time for which the module sleeps between consecutive printing of thread analysis in automatic mode.
- `THREAD_ANALYZER_AUTO_STACK_SIZE`: the stack for thread analyzer automatic thread.
- `THREAD_NAME`: enable this option in the kernel to print the name of the thread instead of its ID.
- `THREAD_RUNTIME_STATS`: enable this option to print thread runtime data such as utilization (This options is automatically selected by `THREAD_ANALYZER`).

## API documentation

### group thread\_analyzer

Module for analyzing threads.

This module implements functions and the configuration that simplifies thread analysis.

### Typedefs

```
typedef void (*thread_analyzer_cb)(struct thread_analyzer_info *info)
```

Thread analyzer stack size callback function.

Callback function with thread analysis information.

**Param info** Thread analysis information.

### Functions

```
void thread_analyzer_run(thread_analyzer_cb cb)
```

Run the thread analyzer and provide information to the callback.

This function analyzes the current state for all threads and calls a given callback on every thread found.

#### Parameters

- *cb* – The callback function handler

```
void thread_analyzer_print(void)
```

Run the thread analyzer and print stack size statistics.

This function runs the thread analyzer and prints the output in standard form.

```
struct thread_analyzer_info
```

```
#include <thread_analyzer.h>
```

### Public Members

```
const char *name
```

The name of the thread or stringified address of the thread handle if name is not set.

```
size_t stack_size
```

The total size of the stack

```
size_t stack_used
```

Stack size in used

## 8.9.2 Core Dump

The core dump module enables dumping the CPU registers and memory content for offline debugging. This module is called when fatal error is encountered, and the data is printed or stored according to which backends are enabled.

## Configuration

Configure this module using the following options.

- `DEBUG_COREDUMP`: enable the module.

Here are the options to enable output backends for core dump:

- `DEBUG_COREDUMP_BACKEND_LOGGING`: use log module for core dump output.
- `DEBUG_COREDUMP_BACKEND_NULL`: fallback core dump backend if other backends cannot be enabled. All output is sent to null.

Here are the choices regarding memory dump:

- `DEBUG_COREDUMP_MEMORY_DUMP_MIN`: only dumps the stack of the exception thread, its thread struct, and some other bare minimal data to support walking the stack in debugger. Use this only if absolute minimum of data dump is desired.

## Usage

When the core dump module is enabled, during fatal error, CPU registers and memory content are being printed or stored according to which backends are enabled. This core dump data can be fed into a custom made GDB server as a remote target for GDB (and other GDB compatible debuggers). CPU registers, memory content and stack can be examined in the debugger.

This usually involves the following steps:

1. Get the core dump log from the device depending on enabled backends. For example, if the log module backend is used, get the log output from the log module backend.
2. Convert the core dump log into a binary format that can be parsed by the GDB server. For example, [scripts/coredump/coredump\\_serial\\_log\\_parser.py](#) can be used to convert the serial console log into a binary file.
3. Start the custom GDB server using the script [scripts/coredump/coredump\\_gdbserver.py](#) with the core dump binary log file, and the Zephyr ELF file as parameters.
4. Start the debugger corresponding to the target architecture.

**Example** This example uses the log module backend tied to serial console. This was done on `qemu_x86` where a null pointer was dereferenced.

This is the core dump log from the serial console, and is stored in `coredump.log`:

```

```

1. Run the core dump serial log converter:

```
./scripts/coredump/coredump_serial_log_parser.py coredump.log coredump.bin
```

2. Start the custom GDB server:

```
./scripts/coredump/coredump_gdbserver.py build/zephyr/zephyr.elf coredump.bin
```

3. Start GDB:

```
<path to SDK>/x86_64-zephyr-elf/bin/x86_64-zephyr-elf-gdb build/zephyr/zephyr.elf
```

4. Inside GDB, connect to the GDB server via port 1234:

```
(gdb) target remote localhost:1234
```

5. Examine the CPU registers:

```
(gdb) info registers
```

Output from GDB:

```
eax            0x0                0
ecx            0x119d74           1154420
edx            0x3f8             1016
ebx            0x0                0
esp            0x119d00           0x119d00 <z_main_stack+844>
ebp            0x119d10           0x119d10 <z_main_stack+860>
esi            0x0                0
edi            0x101aa7           1055399
eip            0x100459           0x100459 <func_3+16>
eflags         0x206             [ PF IF ]
cs             0x8                8
ss             <unavailable>

es             <unavailable>
fs             <unavailable>
gs             <unavailable>
```

6. Examine the backtrace:

```
(gdb) bt
```

Output from GDB:

```
#0  0x00100459 in func_3 (addr=0x0) at zephyr/rtos/zephyr/samples/hello_world/
↳src/main.c:14
#1  0x00100477 in func_2 (addr=0x0) at zephyr/rtos/zephyr/samples/hello_world/
↳src/main.c:21
#2  0x00100492 in func_1 (addr=0x0) at zephyr/rtos/zephyr/samples/hello_world/
↳src/main.c:28
#3  0x001004c8 in main () at zephyr/rtos/zephyr/samples/hello_world/src/main.c:42
```

## File Format

The core dump binary file consists of one file header, one architecture-specific block, and multiple memory blocks. All numbers in the headers below are little endian.

**File Header** The file header consists of the following fields:

Table 4: Core dump binary file header

Field	Data Type	Description
ID	char[2]	Z, E as identifier of file.
Header version	uint16_t	Identify the version of the header. This needs to be incremented whenever the header struct is modified. This allows parser to reject older header versions so it will not incorrectly parse the header.
Target code	uint16_t	Indicate which target (e.g. architecture or SoC) so the parser can instantiate the correct register block parser.
Pointer size	'uint8_t'	Size of uintptr_t in power of 2. (e.g. 5 for 32-bit, 6 for 64-bit). This is needed to accommodate 32-bit and 64-bit target in parsing the memory block addresses.
Flags	uint8_t	
Fatal error reason	unsigned int	Reason for the fatal error, as the same in enum k_fatal_error_reason defined in <a href="#">include/fatal.h</a>

**Architecture-specific Block** The architecture-specific block contains the byte stream of data specific to the target architecture (e.g. CPU registers)

Table 5: Architecture-specific Block

Field	Data Type	Description
ID	char	A to indicate this is a architecture-specific block.
Header version	uint16_t	Identify the version of this block. To be interpreted by the target architecture specific block parser.
Number of bytes	uint16_t	Number of bytes following the header which contains the byte stream for target data. The format of the byte stream is specific to the target and is only being parsed by the target parser.
Register byte stream	uint8_t[]	Contains target architecture specific data.

**Memory Block** The memory block contains the start and end addresses and the data within the memory region.

Table 6: Memory Block

Field	Data Type	Description
ID	char	M to indicate this is a memory block.
Header version	uint16_t	Identify the version of the header. This needs to be incremented whenever the header struct is modified. This allows parser to reject older header versions so it will not incorrectly parse the header.
Start address	uintptr_t	The start address of the memory region.
End address	uintptr_t	The end address of the memory region.
Memory byte stream	uint8_t[]	Contains the memory content between the start and end addresses.

## Adding New Target

The architecture-specific block is target specific and requires new dumping routine and parser for new targets. To add a new target, the following needs to be done:

1. Add a new target code to the enum `coredump_tgt_code` in [include/debug/coredump.h](#).

2. Implement `arch_coredump_tgt_code_get()` simply to return the newly introduced target code.
3. Implement `arch_coredump_info_dump()` to construct a target architecture block and call `coredump_buffer_output()` to output the block to core dump backend.
4. Add a parser to the core dump GDB stub scripts under `scripts/coredump/gdbstubs/`
  1. Extends the `gdbstubs.gdbstub.GdbStub` class.
  2. During `__init__`, store the GDB signal corresponding to the exception reason in `self.gdb_signal`.
  3. Parse the architecture-specific block from `self.logfile.get_arch_data()`. This needs to match the format as implemented in step 3 (inside `arch_coredump_info_dump()`).
  4. Implement the abstract method `handle_register_group_read_packet` where it returns the register group as GDB expected. Refer to GDB's code and documentation on what it is expecting for the new target.
  5. Optionally implement `handle_register_single_read_packet` for registers not covered in the g packet.
5. Extend `get_gdbstub()` in `scripts/coredump/gdbstubs/__init__.py` to return the newly implemented GDB stub.

## API documentation

*group* `coredump_apis`  
Coredump APIs.

### Functions

`void coredump(unsigned int reason, const z_arch_esf_t *esf, struct k_thread *thread)`  
Perform coredump.

Normally, this is called inside `z_fatal_error()` to generate coredump when a fatal error is encountered. This can also be called on demand whenever a coredump is desired.

#### Parameters

- `reason` – Reason for the fatal error
- `esf` – Exception context
- `thread` – Thread information to dump

`void coredump_memory_dump(uintptr_t start_addr, uintptr_t end_addr)`  
Dump memory region.

#### Parameters

- `start_addr` – Start address of memory region to be dumped
- `end_addr` – End address of memory region to be dumped

`void coredump_buffer_output(uint8_t *buf, size_t buflen)`  
Output the buffer via coredump.

This outputs the buffer of byte array to the coredump backend. For example, this can be called to output the coredump section containing registers, or a section for memory dump.

#### Parameters

- `buf` – Buffer to be send to coredump output
- `buflen` – Buffer length

```
int coredump_query(enum coredump_query_id query_id, void *arg)
```

Perform query on coredump subsystem.

Query the coredump subsystem for information, for example, if there is an error.

**Parameters**

- `query_id` – **[in]** Query ID
- `arg` – **[inout]** Pointer to argument for exchanging information

**Returns** Depends on the query

```
int coredump_cmd(enum coredump_cmd_id query_id, void *arg)
```

Perform command on coredump subsystem.

Perform certain on coredump subsystem, for example, output the stored coredump via logging.

**Parameters**

- `cmd_id` – **[in]** Command ID
- `arg` – **[inout]** Pointer to argument for exchanging information

**Returns** Depends on the command

*group arch-coredump*

## Functions

```
void arch_coredump_info_dump(const z_arch_esf_t *esf)
```

Architecture-specific handling during coredump.

This dumps architecture-specific information during coredump.

**Parameters**

- `esf` – Exception Stack Frame (arch-specific)

```
uint16_t arch_coredump_tgt_code_get(void)
```

Get the target code specified by the architecture.

## 8.9.3 GDB stub

### Overview

The gdbstub feature provides an implementation of the GDB Remote Serial Protocol (RSP) that allows you to remotely debug Zephyr using GDB.

The protocol supports different connection types: serial, UDP/IP and TCP/IP. Zephyr currently supports only serial device communication.

The GDB program acts as the client while Zephyr acts as the server. When this feature is enabled, Zephyr stops its execution after `gdb_init()` starts gdbstub service and waits for a GDB connection. Once a connection is established it is possible to synchronously interact with Zephyr. Note that currently it is not possible to asynchronously send commands to the target.

Enable this feature with the `:kconfig: `CONFIG_GDBSTUB`` option.

## Features

The following features are supported:

- Add and remove breakpoints
- Continue and step the target
- Print backtrace
- Read or write general registers
- Read or write the memory

### 8.9.4 Tracing

#### Overview

The tracing feature provides hooks that permits you to collect data from your application and allows tools running on a host to visualize the inner-working of the kernel and various subsystems.

Every system has application-specific events to trace out. Historically, that has implied:

1. Determining the application-specific payload,
2. Choosing suitable serialization-format,
3. Writing the on-target serialization code,
4. Deciding on and writing the I/O transport mechanics,
5. Writing the PC-side deserializer/parser,
6. Writing custom ad-hoc tools for filtering and presentation.

An application can use one of the existing formats or define a custom format by overriding the macros declared in [include/tracing/tracing.h](#).

Different formats, transports and host tools are available and supported in Zephyr.

In fact, I/O varies greatly from system to system. Therefore, it is instructive to create a taxonomy for I/O types when we must ensure the interface between payload/format (Top Layer) and the transport mechanics (bottom Layer) is generic and efficient enough to model these. See the *I/O taxonomy* section below.

#### Serialization Formats

**Common Trace Format (CTF) Support** Common Trace Format, CTF, is an open format and language to describe trace formats. This enables tool reuse, of which line-textual (babeltrace) and graphical (TraceCompass) variants already exist.

CTF should look familiar to C programmers but adds stronger typing. See [CTF - A Flexible, High-performance Binary Trace Format](#).

CTF allows us to formally describe application specific payload and the serialization format, which enables common infrastructure for host tools and parsers and tools for filtering and presentation.

**A Generic Interface** In CTF, an event is serialized to a packet containing one or more fields. As seen from *I/O taxonomy* section below, a bottom layer may:

- perform actions at transaction-start (e.g. mutex-lock),
- process each field in some way (e.g. sync-push emit, concat, enqueue to thread-bound FIFO),
- perform actions at transaction-stop (e.g. mutex-release, emit of concat buffer).

**CTF Top-Layer Example** The CTF\_EVENT macro will serialize each argument to a field:

```
/* Example for illustration */
static inline void ctf_top_foo(uint32_t thread_id, ctf_bounded_string_t name)
{
    CTF_EVENT(
        CTF_LITERAL(uint8_t, 42),
        thread_id,
        name,
        "hello, I was emitted from function: ",
        __func__ /* __func__ is standard since C99 */
    );
}
```

How to serialize and emit fields as well as handling alignment, can be done internally and statically at compile-time in the bottom-layer.

The CTF top layer is enabled using the configuration option `:kconfig: `CONFIG_TRACING_CTF`` and can be used with the different transport backends both in synchronous and asynchronous modes.

**SEGGER SystemView Support** Zephyr provides built-in support for [SEGGER SystemView](#) that can be enabled in any application for platforms that have the required hardware support.

The payload and format used with SystemView is custom to the application and relies on RTT as a transport. Newer versions of SystemView support other transports, for example UART or using snapshot mode (both still not supported in Zephyr).

To enable tracing support with [SEGGER SystemView](#) add the configuration option `:kconfig: `CONFIG_SEGGER_SYSTEMVIEW`` to your project configuration file and set it to y. For example, this can be added to the `synchronization_sample` to visualize fast switching between threads. SystemView can also be used for post-mortem tracing, which can be enabled with `CONFIG_SEGGER_SYSVIEW_POST_MORTEM_MODE`. In this mode, a debugger can be attached after the system has crashed using `west attach` after which the latest data from the internal RAM buffer can be loaded into SystemView:

```
CONFIG_STDOUT_CONSOLE=y
# enable to use thread names
CONFIG_THREAD_NAME=y
CONFIG_SEGGER_SYSTEMVIEW=y
CONFIG_USE_SEGGER_RTT=y
CONFIG_TRACING=y
# enable for post-mortem tracing
CONFIG_SEGGER_SYSVIEW_POST_MORTEM_MODE=n
```

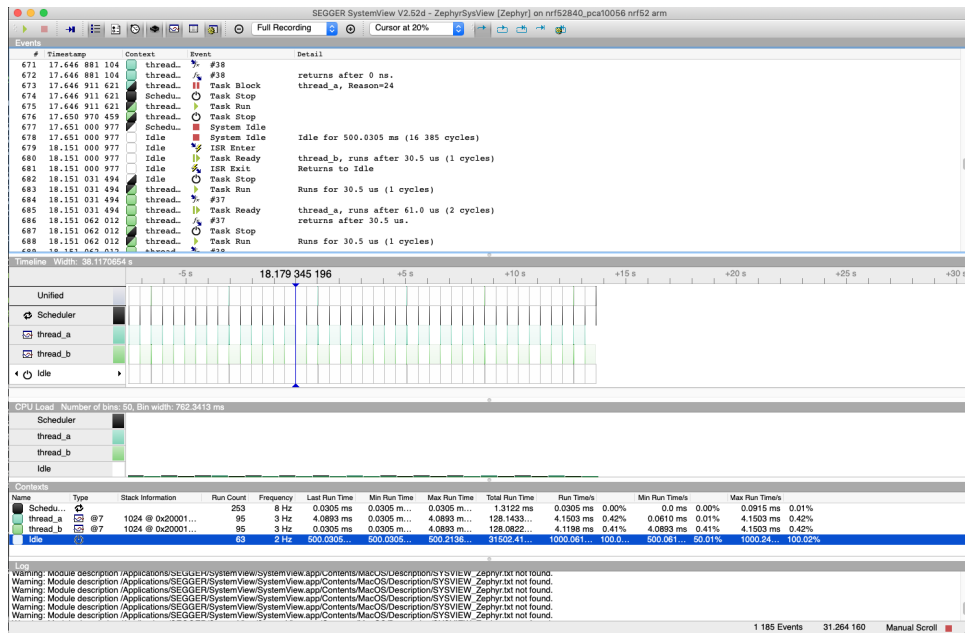

Recent versions of [SEGGER SystemView](#) come with an API translation table for Zephyr which is incomplete and does not match the current level of support available in Zephyr. To use the latest Zephyr API description table, copy the file available in the tree to your local configuration directory to override the builtin table:

```
# On Linux and MacOS
cp ZEPHYR_BASE/subsys/tracing/sysview/SYSVIEW_Zephyr.txt ~/.config/SEGGER/
```

**User-Defined Tracing** This tracing format allows the user to define functions to perform any work desired when a task is switched in or out, when an interrupt is entered or exited, and when the cpu is idle.

Examples include: - simple toggling of GPIO for external scope tracing while minimizing extra cpu load  
- generating/outputting trace data in a non-standard or proprietary format that can not be supported by the other tracing systems

The following functions can be defined by the user:

- void sys\_trace\_thread\_switched\_in\_user(struct k\_thread \*thread)
- void sys\_trace\_thread\_switched\_out\_user(struct k\_thread \*thread)
- void sys\_trace\_isr\_enter\_user()
- void sys\_trace\_isr\_exit\_user()
- void sys\_trace\_idle\_user()

Enable this format with the `:kconfig: `CONFIG_TRACING_USER`` option.

## Transport Backends

The following backends are currently supported:

- UART
- USB
- File (Using native posix port)
- RTT (With SystemView)
- RAM (buffer to be retrieved by a debugger)

## Using Tracing

The sample `samples/subsys/tracing` demonstrates tracing with different formats and backends.

To get started, the simplest way is to use the CTF format with the `native_posix` port, build the sample as follows:

Using west:

```
west build -b native_posix samples/subsys/tracing -- -DCONF_FILE=prj_native_posix_ctf.conf
↪ conf
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsistem:
cmake -B build -GNinja -DBOARD=native_posix -DCONF_FILE=prj_native_posix_ctf.conf
↪ samples/subsys/tracing
```

(continues on next page)

(continued from previous page)

```
# Now run ninja on the generated build system:
ninja -C build
```

You can then run the resulting binary with the option `-trace-file` to generate the tracing data:

```
mkdir data
cp $ZEPHYR_BASE/subsys/tracing/ctf/tsdl/metadata data/
./build/zephyr/zephyr.exe -trace-file=data/channel0_0
```

The resulting CTF output can be visualized using babeltrace or TraceCompass by pointing the tool to the data directory with the metadata and trace files.

**Using RAM backend** For devices that do not have available I/O for tracing such as USB or UART but have enough RAM to collect trace datas, the ram backend can be enabled with configuration `CONFIG_TRACING_BACKEND_RAM`. Adjust `CONFIG_RAM_TRACING_BUFFER_SIZE` to be able to record enough traces for your needs. Then thanks to a runtime debugger such as gdb this buffer can be fetched from the target to an host computer:

```
(gdb) dump binary memory data/channel0_0 <ram_tracing_start> <ram_tracing_end>
```

The resulting `channel0_0` file have to be placed in a directory with the metadata file like the other backend.

## Visualisation Tools

**TraceCompass** TraceCompass is an open source tool that visualizes CTF events such as thread scheduling and interrupts, and is helpful to find unintended interactions and resource conflicts on complex systems.

See also the presentation by Ericsson, [Advanced Trouble-shooting Of Real-time Systems](#).

## Future LTTng Inspiration

Currently, the top-layer provided here is quite simple and bare-bones, and needlessly copied from Zephyr's Segger SystemView debug module.

For an OS like Zephyr, it would make sense to draw inspiration from Linux's LTTng and change the top-layer to serialize to the same format. Doing this would enable direct reuse of TraceCompass' canned analyses for Linux. Alternatively, LTTng-analyses in TraceCompass could be customized to Zephyr. It is ongoing work to enable TraceCompass visibility of Zephyr in a target-agnostic and open source way.

## I/O Taxonomy

- Atomic Push/Produce/Write/Enqueue:
  - **synchronous:** means data-transmission has completed with the return of the call.
  - **asynchronous:** means data-transmission is pending or ongoing with the return of the call. Usually, interrupts/callbacks/signals or polling is used to determine completion.
  - **buffered:** means data-transmissions are copied and grouped together to form a larger ones. Usually for amortizing overhead (burst dequeue) or jitter-mitigation (steady dequeue).

### Examples:

- **sync unbuffered** E.g. PIO via GPIOs having steady stream, no extra FIFO memory needed. Low jitter but may be less efficient (cant amortize the overhead of writing).

- **sync buffered** E.g. `fwrite()` or enqueueing into FIFO. Blockingly burst the FIFO when its buffer-waterlevel exceeds threshold. Jitter due to bursts may lead to missed deadlines.
- **async unbuffered** E.g. DMA, or zero-copying in shared memory. Be careful of data hazards, race conditions, etc!
- **async buffered** E.g. enqueueing into FIFO.
- Atomic Pull/Consume/Read/Dequeue:
  - **synchronous**: means data-reception has completed with the return of the call.
  - **asynchronous**: means data-reception is pending or ongoing with the return of the call. Usually, interrupts/callbacks/signals or polling is used to determine completion.
  - **buffered**: means data is copied-in in larger chunks than request-size. Usually for amortizing wait-time.

**Examples:**

- **sync unbuffered** E.g. Blocking read-call, `fread()` or SPI-read, zero-copying in shared memory.
- **sync buffered** E.g. Blocking read-call with caching applied. Makes sense if read pattern exhibits spatial locality.
- **async unbuffered** E.g. zero-copying in shared memory. Be careful of data hazards, race conditions, etc!
- **async buffered** E.g. `aio_read()` or DMA.

Unfortunately, I/O may not be atomic and may, therefore, require locking. Locking may not be needed if multiple independent channels are available.

- **The system has non-atomic write and one shared channel** E.g. UART. Locking required.

```
lock(); emit(a); emit(b); emit(c); release();
```
- **The system has non-atomic write but many channels** E.g. Multi-UART. Lock-free if the bottom-layer maps each Zephyr thread+ISR to its own channel, thus alleviating races as each thread is sequentially consistent with itself.

```
emit(a,thread_id); emit(b,thread_id); emit(c,thread_id);
```
- **The system has atomic write but one shared channel** E.g. `native_posix` or board with DMA. May or may not need locking.

```
emit(a ## b ## c); /* Concat to buffer */  
lock(); emit(a); emit(b); emit(c); release(); /* No extra mem */
```
- **The system has atomic write and many channels** E.g. `native_posix` or board with multi-channel DMA. Lock-free.

```
emit(a ## b ## c, thread_id);
```

**API****Common**

`group tracing_apis`  
Tracing APIs.

## Functions

`void sys_trace_isr_enter(void)`

Called when entering an ISR.

`void sys_trace_isr_exit(void)`

Called when exiting an ISR.

`void sys_trace_isr_exit_to_scheduler(void)`

Called when exiting an ISR and switching to scheduler.

`void sys_trace_idle(void)`

Called when the cpu enters the idle state.

## Threads

*group* `thread_tracing_apis`

Thread Tracing APIs.

## Defines

`sys_port_trace_k_thread_foreach_enter()`

Called when entering a `k_thread_foreach` call.

`sys_port_trace_k_thread_foreach_exit()`

Called when exiting a `k_thread_foreach` call.

`sys_port_trace_k_thread_foreach_unlocked_enter()`

Called when entering a `k_thread_foreach_unlocked`.

`sys_port_trace_k_thread_foreach_unlocked_exit()`

Called when exiting a `k_thread_foreach_unlocked`.

`sys_port_trace_k_thread_create(new_thread)`

Trace creating a Thread.

### Parameters

- `new_thread` – Thread object

`sys_port_trace_k_thread_user_mode_enter()`

Trace Thread entering user mode.

`sys_port_trace_k_thread_join_enter(thread, timeout)`

Called when entering a `k_thread_join`.

### Parameters

- `thread` – Thread object
- `timeout` – Timeout period

`sys_port_trace_k_thread_join_blocking(thread, timeout)`

Called when `k_thread_join` blocks.

### Parameters

- `thread` – Thread object
- `timeout` – Timeout period

`sys_port_trace_k_thread_join_exit(thread, timeout, ret)`

Called when exiting `k_thread_join`.

**Parameters**

- `thread` – Thread object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_thread_sleep_enter(timeout)`

Called when entering `k_thread_sleep`.

**Parameters**

- `timeout` – Timeout period

`sys_port_trace_k_thread_sleep_exit(timeout, ret)`

Called when exiting `k_thread_sleep`.

**Parameters**

- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_thread_msleep_enter(ms)`

Called when entering `k_thread_msleep`.

**Parameters**

- `ms` – Duration in milliseconds

`sys_port_trace_k_thread_msleep_exit(ms, ret)`

Called when exiting `k_thread_msleep`.

**Parameters**

- `ms` – Duration in milliseconds
- `ret` – Return value

`sys_port_trace_k_thread_usleep_enter(us)`

Called when entering `k_thread_usleep`.

**Parameters**

- `us` – Duration in microseconds

`sys_port_trace_k_thread_usleep_exit(us, ret)`

Called when exiting `k_thread_usleep`.

**Parameters**

- `us` – Duration in microseconds
- `ret` – Return value

`sys_port_trace_k_thread_busy_wait_enter(usec_to_wait)`

Called when entering `k_thread_busy_wait`.

**Parameters**

- `usec_to_wait` – Duration in microseconds

`sys_port_trace_k_thread_busy_wait_exit(usec_to_wait)`

Called when exiting `k_thread_busy_wait`.

**Parameters**

- `usec_to_wait` – Duration in microseconds

`sys_port_trace_k_thread_yield()`

Called when a thread yields.

`sys_port_trace_k_thread_wakeup(thread)`

Called when a thread wakes up.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_start(thread)`

Called when a thread is started.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_abort(thread)`

Called when a thread is being aborted.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_priority_set(thread)`

Called when setting priority of a thread.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_suspend_enter(thread)`

Called when a thread enters the `k_thread_suspend` function.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_suspend_exit(thread)`

Called when a thread exits the `k_thread_suspend` function.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_resume_enter(thread)`

Called when a thread enters the resume from suspension function.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_resume_exit(thread)`

Called when a thread exits the resumed from suspension function.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_sched_lock()`

Called when the thread scheduler is locked.

`sys_port_trace_k_thread_sched_unlock()`

Called when the thread scheduler is unlocked.

`sys_port_trace_k_thread_name_set(thread, ret)`

Called when a thread name is set.

**Parameters**

- `thread` – Thread object
- `ret` – Return value

`sys_port_trace_k_thread_switched_out()`

Called before a thread has been selected to run.

`sys_port_trace_k_thread_switched_in()`

Called after a thread has been selected to run.

`sys_port_trace_k_thread_ready(thread)`

Called when a thread is ready to run.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_pend(thread)`

Called when a thread is pending.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_info(thread)`

Provide information about specific thread.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_sched_wakeup(thread)`

Trace implicit thread wakeup invocation by the scheduler.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_sched_abort(thread)`

Trace implicit thread abort invocation by the scheduler.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_sched_priority_set(thread, prio)`

Trace implicit thread set priority invocation by the scheduler.

**Parameters**

- `thread` – Thread object
- `prio` – Thread priority

`sys_port_trace_k_thread_sched_ready(thread)`

Trace implicit thread ready invocation by the scheduler.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_sched_pend(thread)`

Trace implicit thread pend invocation by the scheduler.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_sched_resume(thread)`

Trace implicit thread resume invocation by the scheduler.

**Parameters**

- `thread` – Thread object

`sys_port_trace_k_thread_sched_suspend(thread)`

Trace implicit thread suspend invocation by the scheduler.

**Parameters**

- `thread` – Thread object

## Work Queues

*group* `work_tracing_apis`

Work Tracing APIs.

## Defines

`sys_port_trace_k_work_init(work)`

Trace initialisation of a Work structure.

**Parameters**

- `work` – Work structure

`sys_port_trace_k_work_submit_to_queue_enter(queue, work)`

Trace submit work to work queue call entry.

**Parameters**

- `queue` – Work queue structure
- `work` – Work structure

`sys_port_trace_k_work_submit_to_queue_exit(queue, work, ret)`

Trace submit work to work queue call exit.

**Parameters**

- `queue` – Work queue structure
- `work` – Work structure
- `ret` – Return value

`sys_port_trace_k_work_submit_enter(work)`

Trace submit work to system work queue call entry.

**Parameters**

- `work` – Work structure

`sys_port_trace_k_work_submit_exit(work, ret)`

Trace submit work to system work queue call exit.

**Parameters**

- `work` – Work structure
- `ret` – Return value

`sys_port_trace_k_work_flush_enter(work)`

Trace flush work call entry.

**Parameters**

- `work` – Work structure

`sys_port_trace_k_work_flush_blocking(work, timeout)`

Trace flush work call blocking.

**Parameters**

- `work` – Work structure
- `timeout` – Timeout period

`sys_port_trace_k_work_flush_exit(work, ret)`

Trace flush work call exit.

**Parameters**

- `work` – Work structure
- `ret` – Return value

`sys_port_trace_k_work_cancel_enter(work)`

Trace cancel work call entry.

**Parameters**

- `work` – Work structure

`sys_port_trace_k_work_cancel_exit(work, ret)`

Trace cancel work call exit.

**Parameters**

- `work` – Work structure
- `ret` – Return value

`sys_port_trace_k_work_cancel_sync_enter(work, sync)`

Trace cancel sync work call entry.

**Parameters**

- `work` – Work structure
- `sync` – Sync object

`sys_port_trace_k_work_cancel_sync_blocking(work, sync)`

Trace cancel sync work call blocking.

**Parameters**

- `work` – Work structure
- `sync` – Sync object

`sys_port_trace_k_work_cancel_sync_exit(work, sync, ret)`

Trace cancel sync work call exit.

**Parameters**

- `work` – Work structure
- `sync` – Sync object
- `ret` – Return value

## Poll

*group* `poll_tracing_apis`

Poll Tracing APIs.

## Defines

`sys_port_trace_k_poll_api_event_init(event)`

Trace initialisation of a Poll Event.

**Parameters**

- `event` – Poll Event

`sys_port_trace_k_poll_api_poll_enter(events)`

Trace Polling call start.

**Parameters**

- `events` – Poll Events

`sys_port_trace_k_poll_api_poll_exit(events, ret)`

Trace Polling call outcome.

**Parameters**

- `events` – Poll Events
- `ret` – Return value

`sys_port_trace_k_poll_api_signal_init(signal)`

Trace initialisation of a Poll Signal.

**Parameters**

- `signal` – Poll Signal

`sys_port_trace_k_poll_api_signal_reset(signal)`

Trace resetting of Poll Signal.

**Parameters**

- `signal` – Poll Signal

`sys_port_trace_k_poll_api_signal_check(signal)`

Trace checking of Poll Signal.

**Parameters**

- `signal` – Poll Signal

`sys_port_trace_k_poll_api_signal_raise(signal, ret)`

Trace raising of Poll Signal.

**Parameters**

- `signal` – Poll Signal
- `ret` – Return value

## Semaphore

*group* `sem_tracing_apis`

Semaphore Tracing APIs.

### Defines

`sys_port_trace_k_sem_init(sem, ret)`

Trace initialisation of a Semaphore.

**Parameters**

- `sem` – Semaphore object
- `ret` – Return value

`sys_port_trace_k_sem_give_enter(sem)`

Trace giving a Semaphore entry.

**Parameters**

- `sem` – Semaphore object

`sys_port_trace_k_sem_give_exit(sem)`

Trace giving a Semaphore exit.

**Parameters**

- `sem` – Semaphore object

`sys_port_trace_k_sem_take_enter(sem, timeout)`

Trace taking a Semaphore attempt start.

**Parameters**

- `sem` – Semaphore object
- `timeout` – Timeout period

`sys_port_trace_k_sem_take_blocking(sem, timeout)`

Trace taking a Semaphore attempt blocking.

**Parameters**

- `sem` – Semaphore object
- `timeout` – Timeout period

`sys_port_trace_k_sem_take_exit(sem, timeout, ret)`

Trace taking a Semaphore attempt outcome.

**Parameters**

- `sem` – Semaphore object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_sem_reset(sem)`

Trace resetting a Semaphore.

**Parameters**

- `sem` – Semaphore object

## Mutex

*group* `mutex_tracing_apis`

Mutex Tracing APIs.

## Defines

`sys_port_trace_k_mutex_init(mutex, ret)`

Trace initialization of Mutex.

**Parameters**

- `mutex` – Mutex object
- `ret` – Return value

`sys_port_trace_k_mutex_lock_enter(mutex, timeout)`

Trace Mutex lock attempt start.

**Parameters**

- `mutex` – Mutex object
- `timeout` – Timeout period

`sys_port_trace_k_mutex_lock_blocking(mutex, timeout)`

Trace Mutex lock attempt blocking.

**Parameters**

- `mutex` – Mutex object
- `timeout` – Timeout period

`sys_port_trace_k_mutex_lock_exit(mutex, timeout, ret)`

Trace Mutex lock attempt outcome.

**Parameters**

- `mutex` – Mutex object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_mutex_unlock_enter(mutex)`

Trace Mutex unlock entry.

**Parameters**

- `mutex` – Mutex object

`sys_port_trace_k_mutex_unlock_exit(mutex, ret)`

Trace Mutex unlock exit.

## Condition Variables

*group* `condvar_tracing_apis`

Conditional Variable Tracing APIs.

## Defines

`sys_port_trace_k_condvar_init(condvar, ret)`

Trace initialization of Conditional Variable.

### Parameters

- `condvar` – Conditional Variable object
- `ret` – Return value

`sys_port_trace_k_condvar_signal_enter(condvar)`

Trace Conditional Variable signaling start.

### Parameters

- `condvar` – Conditional Variable object

`sys_port_trace_k_condvar_signal_blocking(condvar, timeout)`

Trace Conditional Variable signaling blocking.

### Parameters

- `condvar` – Conditional Variable object
- `timeout` – Timeout period

`sys_port_trace_k_condvar_signal_exit(condvar, ret)`

Trace Conditional Variable signaling outcome.

### Parameters

- `condvar` – Conditional Variable object
- `ret` – Return value

`sys_port_trace_k_condvar_broadcast_enter(condvar)`

Trace Conditional Variable broadcast enter.

### Parameters

- `condvar` – Conditional Variable object

`sys_port_trace_k_condvar_broadcast_exit(condvar, ret)`

Trace Conditional Variable broadcast exit.

### Parameters

- `condvar` – Conditional Variable object
- `ret` – Return value

`sys_port_trace_k_condvar_wait_enter(condvar)`

Trace Conditional Variable wait enter.

### Parameters

- `condvar` – Conditional Variable object

`sys_port_trace_k_condvar_wait_exit(condvar, ret)`

Trace Conditional Variable wait exit.

### Parameters

- `condvar` – Conditional Variable object
- `ret` – Return value

## Queues

*group* queue\_tracing\_apis

Queue Tracing APIs.

### Defines

sys\_port\_trace\_k\_queue\_init(queue)

Trace initialization of Queue.

#### Parameters

- queue – Queue object

sys\_port\_trace\_k\_queue\_cancel\_wait(queue)

Trace Queue cancel wait.

#### Parameters

- queue – Queue object

sys\_port\_trace\_k\_queue\_queue\_insert\_enter(queue, alloc)

Trace Queue insert attempt entry.

#### Parameters

- queue – Queue object
- alloc – Allocation flag

sys\_port\_trace\_k\_queue\_queue\_insert\_blocking(queue, alloc, timeout)

Trace Queue insert attempt blocking.

#### Parameters

- queue – Queue object
- alloc – Allocation flag
- timeout – Timeout period

sys\_port\_trace\_k\_queue\_queue\_insert\_exit(queue, alloc, ret)

Trace Queue insert attempt outcome.

#### Parameters

- queue – Queue object
- alloc – Allocation flag
- ret – Return value

sys\_port\_trace\_k\_queue\_append\_enter(queue)

Trace Queue append enter.

#### Parameters

- queue – Queue object

sys\_port\_trace\_k\_queue\_append\_exit(queue)

Trace Queue append exit.

#### Parameters

- queue – Queue object

`sys_port_trace_k_queue_alloc_append_enter(queue)`

Trace Queue alloc append enter.

**Parameters**

- `queue` – Queue object

`sys_port_trace_k_queue_alloc_append_exit(queue, ret)`

Trace Queue alloc append exit.

**Parameters**

- `queue` – Queue object
- `ret` – Return value

`sys_port_trace_k_queue_prepend_enter(queue)`

Trace Queue prepend enter.

**Parameters**

- `queue` – Queue object

`sys_port_trace_k_queue_prepend_exit(queue)`

Trace Queue prepend exit.

**Parameters**

- `queue` – Queue object

`sys_port_trace_k_queue_alloc_prepend_enter(queue)`

Trace Queue alloc prepend enter.

**Parameters**

- `queue` – Queue object

`sys_port_trace_k_queue_alloc_prepend_exit(queue, ret)`

Trace Queue alloc prepend exit.

**Parameters**

- `queue` – Queue object
- `ret` – Return value

`sys_port_trace_k_queue_insert_enter(queue)`

Trace Queue insert attempt entry.

**Parameters**

- `queue` – Queue object

`sys_port_trace_k_queue_insert_blocking(queue, timeout)`

Trace Queue insert attempt blocking.

**Parameters**

- `queue` – Queue object
- `timeout` – Timeout period

`sys_port_trace_k_queue_insert_exit(queue)`

Trace Queue insert attempt exit.

**Parameters**

- `queue` – Queue object

`sys_port_trace_k_queue_append_list_enter(queue)`

Trace Queue append list enter.

**Parameters**

- `queue` – Queue object

`sys_port_trace_k_queue_append_list_exit(queue, ret)`

Trace Queue append list exit.

**Parameters**

- `queue` – Queue object
- `ret` – Return value

`sys_port_trace_k_queue_merge_slist_enter(queue)`

Trace Queue merge slist enter.

**Parameters**

- `queue` – Queue object

`sys_port_trace_k_queue_merge_slist_exit(queue, ret)`

Trace Queue merge slist exit.

**Parameters**

- `queue` – Queue object
- `ret` – Return value

`sys_port_trace_k_queue_get_enter(queue, timeout)`

Trace Queue get attempt enter.

**Parameters**

- `queue` – Queue object
- `timeout` – Timeout period

`sys_port_trace_k_queue_get_blocking(queue, timeout)`

Trace Queue get attempt blockings.

**Parameters**

- `queue` – Queue object
- `timeout` – Timeout period

`sys_port_trace_k_queue_get_exit(queue, timeout, ret)`

Trace Queue get attempt outcome.

**Parameters**

- `queue` – Queue object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_queue_remove_enter(queue)`

Trace Queue remove enter.

**Parameters**

- `queue` – Queue object

`sys_port_trace_k_queue_remove_exit(queue, ret)`

Trace Queue remove exit.

**Parameters**

- `queue` – Queue object
- `ret` – Return value

`sys_port_trace_k_queue_unique_append_enter(queue)`

Trace Queue unique append enter.

**Parameters**

- `queue` – Queue object

`sys_port_trace_k_queue_unique_append_exit(queue, ret)`

Trace Queue unique append exit.

**Parameters**

- `queue` – Queue object
- `ret` – Return value

`sys_port_trace_k_queue_peek_head(queue, ret)`

Trace Queue peek head.

**Parameters**

- `queue` – Queue object
- `ret` – Return value

`sys_port_trace_k_queue_peek_tail(queue, ret)`

Trace Queue peek tail.

**Parameters**

- `queue` – Queue object
- `ret` – Return value

## FIFO

*group* `fifo_tracing_apis`

FIFO Tracing APIs.

### Defines

`sys_port_trace_k_fifo_init_enter(fifo)`

Trace initialization of FIFO Queue entry.

**Parameters**

- `fifo` – FIFO object

`sys_port_trace_k_fifo_init_exit(fifo)`

Trace initialization of FIFO Queue exit.

**Parameters**

- `fifo` – FIFO object

`sys_port_trace_k_fifo_cancel_wait_enter(fifo)`

Trace FIFO Queue cancel wait entry.

**Parameters**

- `fifo` – FIFO object

`sys_port_trace_k_fifo_cancel_wait_exit(fifo)`

Trace FIFO Queue cancel wait exit.

**Parameters**

- `fifo` – FIFO object

`sys_port_trace_k_fifo_put_enter(fifo, data)`

Trace FIFO Queue put entry.

**Parameters**

- `fifo` – FIFO object
- `data` – Data item

`sys_port_trace_k_fifo_put_exit(fifo, data)`

Trace FIFO Queue put exit.

**Parameters**

- `fifo` – FIFO object
- `data` – Data item

`sys_port_trace_k_fifo_alloc_put_enter(fifo, data)`

Trace FIFO Queue alloc put entry.

**Parameters**

- `fifo` – FIFO object
- `data` – Data item

`sys_port_trace_k_fifo_alloc_put_exit(fifo, data, ret)`

Trace FIFO Queue alloc put exit.

**Parameters**

- `fifo` – FIFO object
- `data` – Data item
- `ret` – Return value

`sys_port_trace_k_fifo_alloc_put_list_enter(fifo, head, tail)`

Trace FIFO Queue put list entry.

**Parameters**

- `fifo` – FIFO object
- `head` – First ll-node
- `tail` – Last ll-node

`sys_port_trace_k_fifo_alloc_put_list_exit(fifo, head, tail)`

Trace FIFO Queue put list exit.

**Parameters**

- `fifo` – FIFO object
- `head` – First ll-node

- `tail` – Last ll-node

`sys_port_trace_k_fifo_alloc_put_slist_enter(fifo, list)`

Trace FIFO Queue put slist entry.

**Parameters**

- `fifo` – FIFO object
- `list` – Syslist object

`sys_port_trace_k_fifo_alloc_put_slist_exit(fifo, list)`

Trace FIFO Queue put slist exit.

**Parameters**

- `fifo` – FIFO object
- `list` – Syslist object

`sys_port_trace_k_fifo_get_enter(fifo, timeout)`

Trace FIFO Queue get entry.

**Parameters**

- `fifo` – FIFO object
- `timeout` – Timeout period

`sys_port_trace_k_fifo_get_exit(fifo, timeout, ret)`

Trace FIFO Queue get exit.

**Parameters**

- `fifo` – FIFO object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_fifo_peek_head_entry(fifo)`

Trace FIFO Queue peek head entry.

**Parameters**

- `fifo` – FIFO object

`sys_port_trace_k_fifo_peek_head_exit(fifo, ret)`

Trace FIFO Queue peek head exit.

**Parameters**

- `fifo` – FIFO object
- `ret` – Return value

`sys_port_trace_k_fifo_peek_tail_entry(fifo)`

Trace FIFO Queue peek tail entry.

**Parameters**

- `fifo` – FIFO object

`sys_port_trace_k_fifo_peek_tail_exit(fifo, ret)`

Trace FIFO Queue peek tail exit.

**Parameters**

- `fifo` – FIFO object
- `ret` – Return value

## LIFO

*group* lifo\_tracing\_apis

LIFO Tracing APIs.

### Defines

`sys_port_trace_k_lifo_init_enter(lifo)`

Trace initialization of LIFO Queue entry.

#### Parameters

- `lifo` – LIFO object

`sys_port_trace_k_lifo_init_exit(lifo)`

Trace initialization of LIFO Queue exit.

#### Parameters

- `lifo` – LIFO object

`sys_port_trace_k_lifo_put_enter(lifo, data)`

Trace LIFO Queue put entry.

#### Parameters

- `lifo` – LIFO object
- `data` – Data item

`sys_port_trace_k_lifo_put_exit(lifo, data)`

Trace LIFO Queue put exit.

#### Parameters

- `lifo` – LIFO object
- `data` – Data item

`sys_port_trace_k_lifo_alloc_put_enter(lifo, data)`

Trace LIFO Queue alloc put entry.

#### Parameters

- `lifo` – LIFO object
- `data` – Data item

`sys_port_trace_k_lifo_alloc_put_exit(lifo, data, ret)`

Trace LIFO Queue alloc put exit.

#### Parameters

- `lifo` – LIFO object
- `data` – Data item
- `ret` – Return value

`sys_port_trace_k_lifo_get_enter(lifo, timeout)`

Trace LIFO Queue get entry.

#### Parameters

- `lifo` – LIFO object
- `timeout` – Timeout period

`sys_port_trace_k_lifo_get_exit(lifo, timeout, ret)`

Trace LIFO Queue get exit.

**Parameters**

- `lifo` – LIFO object
- `timeout` – Timeout period
- `ret` – Return value

## Stacks

*group* `stack_tracing_apis`

Stack Tracing APIs.

## Defines

`sys_port_trace_k_stack_init(stack)`

Trace initialization of Stack.

**Parameters**

- `stack` – Stack object

`sys_port_trace_k_stack_alloc_init_enter(stack)`

Trace Stack alloc init attempt entry.

**Parameters**

- `stack` – Stack object

`sys_port_trace_k_stack_alloc_init_exit(stack, ret)`

Trace Stack alloc init outcome.

**Parameters**

- `stack` – Stack object
- `ret` – Return value

`sys_port_trace_k_stack_cleanup_enter(stack)`

Trace Stack cleanup attempt entry.

**Parameters**

- `stack` – Stack object

`sys_port_trace_k_stack_cleanup_exit(stack, ret)`

Trace Stack cleanup outcome.

**Parameters**

- `stack` – Stack object
- `ret` – Return value

`sys_port_trace_k_stack_push_enter(stack)`

Trace Stack push attempt entry.

**Parameters**

- `stack` – Stack object

`sys_port_trace_k_stack_push_exit(stack, ret)`

Trace Stack push attempt outcome.

**Parameters**

- `stack` – Stack object
- `ret` – Return value

`sys_port_trace_k_stack_pop_enter(stack, timeout)`

Trace Stack pop attempt entry.

**Parameters**

- `stack` – Stack object
- `timeout` – Timeout period

`sys_port_trace_k_stack_pop_blocking(stack, timeout)`

Trace Stack pop attempt blocking.

**Parameters**

- `stack` – Stack object
- `timeout` – Timeout period

`sys_port_trace_k_stack_pop_exit(stack, timeout, ret)`

Trace Stack pop attempt outcome.

**Parameters**

- `stack` – Stack object
- `timeout` – Timeout period
- `ret` – Return value

## Message Queues

*group* `msgq_tracing_apis`

Message Queue Tracing APIs.

## Defines

`sys_port_trace_k_msgq_init(msgq)`

Trace initialization of Message Queue.

**Parameters**

- `msgq` – Message Queue object

`sys_port_trace_k_msgq_alloc_init_enter(msgq)`

Trace Message Queue alloc init attempt entry.

**Parameters**

- `msgq` – Message Queue object

`sys_port_trace_k_msgq_alloc_init_exit(msgq, ret)`

Trace Message Queue alloc init attempt outcome.

**Parameters**

- `msgq` – Message Queue object
- `ret` – Return value

`sys_port_trace_k_msgq_cleanup_enter(msgq)`

Trace Message Queue cleanup attempt entry.

**Parameters**

- `msgq` – Message Queue object

`sys_port_trace_k_msgq_cleanup_exit(msgq, ret)`

Trace Message Queue cleanup attempt outcome.

**Parameters**

- `msgq` – Message Queue object
- `ret` – Return value

`sys_port_trace_k_msgq_put_enter(msgq, timeout)`

Trace Message Queue put attempt entry.

**Parameters**

- `msgq` – Message Queue object
- `timeout` – Timeout period

`sys_port_trace_k_msgq_put_blocking(msgq, timeout)`

Trace Message Queue put attempt blocking.

**Parameters**

- `msgq` – Message Queue object
- `timeout` – Timeout period

`sys_port_trace_k_msgq_put_exit(msgq, timeout, ret)`

Trace Message Queue put attempt outcome.

**Parameters**

- `msgq` – Message Queue object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_msgq_get_enter(msgq, timeout)`

Trace Message Queue get attempt entry.

**Parameters**

- `msgq` – Message Queue object
- `timeout` – Timeout period

`sys_port_trace_k_msgq_get_blocking(msgq, timeout)`

Trace Message Queue get attempt blockings.

**Parameters**

- `msgq` – Message Queue object
- `timeout` – Timeout period

`sys_port_trace_k_msgq_get_exit(msgq, timeout, ret)`

Trace Message Queue get attempt outcome.

**Parameters**

- `msgq` – Message Queue object
- `timeout` – Timeout period

- `ret` – Return value

`sys_port_trace_k_msgq_peek(msgq, ret)`

Trace Message Queue peek.

#### Parameters

- `msgq` – Message Queue object
- `ret` – Return value

`sys_port_trace_k_msgq_purge(msgq)`

Trace Message Queue purge.

#### Parameters

- `msgq` – Message Queue object

## Mailbox

*group* `mbox_tracing_apis`

Mailbox Tracing APIs.

## Defines

`sys_port_trace_k_mbox_init(mbox)`

Trace initialization of Mailbox.

#### Parameters

- `mbox` – Mailbox object

`sys_port_trace_k_mbox_message_put_enter(mbox, timeout)`

Trace Mailbox message put attempt entry.

#### Parameters

- `mbox` – Mailbox object
- `timeout` – Timeout period

`sys_port_trace_k_mbox_message_put_blocking(mbox, timeout)`

Trace Mailbox message put attempt blocking.

#### Parameters

- `mbox` – Mailbox object
- `timeout` – Timeout period

`sys_port_trace_k_mbox_message_put_exit(mbox, timeout, ret)`

Trace Mailbox message put attempt outcome.

#### Parameters

- `mbox` – Mailbox object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_mbox_put_enter(mbox, timeout)`

Trace Mailbox put attempt entry.

#### Parameters

- `mbox` – Mailbox object

- `timeout` – Timeout period

`sys_port_trace_k_mbox_put_exit(mbox, timeout, ret)`

Trace Mailbox put attempt blocking.

#### Parameters

- `mbox` – Mailbox object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_mbox_async_put_enter(mbox, sem)`

Trace Mailbox async put entry.

#### Parameters

- `mbox` – Mailbox object
- `sem` – Semaphore object

`sys_port_trace_k_mbox_async_put_exit(mbox, sem)`

Trace Mailbox async put exit.

#### Parameters

- `mbox` – Mailbox object
- `sem` – Semaphore object

`sys_port_trace_k_mbox_get_enter(mbox, timeout)`

Trace Mailbox get attempt entry.

#### Parameters

- `mbox` – Mailbox entry
- `timeout` – Timeout period

`sys_port_trace_k_mbox_get_blocking(mbox, timeout)`

Trace Mailbox get attempt blocking.

#### Parameters

- `mbox` – Mailbox entry
- `timeout` – Timeout period

`sys_port_trace_k_mbox_get_exit(mbox, timeout, ret)`

Trace Mailbox get attempt outcome.

#### Parameters

- `mbox` – Mailbox entry
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_mbox_data_get(rx_msg)`

Trace Mailbox data get.

`rx_msg` Receive Message object

## Pipes

*group* `pipe_tracing_apis`

Pipe Tracing APIs.

## Defines

`sys_port_trace_k_pipe_init(pipe)`

Trace initialization of Pipe.

### Parameters

- `pipe` – Pipe object

`sys_port_trace_k_pipe_cleanup_enter(pipe)`

Trace Pipe cleanup entry.

### Parameters

- `pipe` – Pipe object

`sys_port_trace_k_pipe_cleanup_exit(pipe, ret)`

Trace Pipe cleanup exit.

### Parameters

- `pipe` – Pipe object
- `ret` – Return value

`sys_port_trace_k_pipe_alloc_init_enter(pipe)`

Trace Pipe alloc init entry.

### Parameters

- `pipe` – Pipe object

`sys_port_trace_k_pipe_alloc_init_exit(pipe, ret)`

Trace Pipe alloc init exit.

### Parameters

- `pipe` – Pipe object
- `ret` – Return value

`sys_port_trace_k_pipe_put_enter(pipe, timeout)`

Trace Pipe put attempt entry.

### Parameters

- `pipe` – Pipe object
- `timeout` – Timeout period

`sys_port_trace_k_pipe_put_blocking(pipe, timeout)`

Trace Pipe put attempt blocking.

### Parameters

- `pipe` – Pipe object
- `timeout` – Timeout period

`sys_port_trace_k_pipe_put_exit(pipe, timeout, ret)`

Trace Pipe put attempt outcome.

### Parameters

- `pipe` – Pipe object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_pipe_get_enter(pipe, timeout)`

Trace Pipe get attempt entry.

**Parameters**

- `pipe` – Pipe object
- `timeout` – Timeout period

`sys_port_trace_k_pipe_get_blocking(pipe, timeout)`

Trace Pipe get attempt blocking.

**Parameters**

- `pipe` – Pipe object
- `timeout` – Timeout period

`sys_port_trace_k_pipe_get_exit(pipe, timeout, ret)`

Trace Pipe get attempt outcome.

**Parameters**

- `pipe` – Pipe object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_pipe_block_put_enter(pipe, sem)`

Trace Pipe block put enter.

**Parameters**

- `pipe` – Pipe object
- `sem` – Semaphore object

`sys_port_trace_k_pipe_block_put_exit(pipe, sem)`

Trace Pipe block put exit.

**Parameters**

- `pipe` – Pipe object
- `sem` – Semaphore object

## Heaps

*group* `heap_tracing_apis`

Heap Tracing APIs.

### Defines

`sys_port_trace_k_heap_init(h)`

Trace initialization of Heap.

**Parameters**

- `h` – Heap object

`sys_port_trace_k_heap_aligned_alloc_enter(h, timeout)`

Trace Heap aligned alloc attempt entry.

**Parameters**

- `h` – Heap object

- `timeout` – Timeout period

`sys_port_trace_k_heap_aligned_alloc_blocking(h, timeout)`

Trace Heap align alloc attempt blocking.

**Parameters**

- `h` – Heap object
- `timeout` – Timeout period

`sys_port_trace_k_heap_aligned_alloc_exit(h, timeout, ret)`

Trace Heap align alloc attempt outcome.

**Parameters**

- `h` – Heap object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_heap_alloc_enter(h, timeout)`

Trace Heap alloc enter.

**Parameters**

- `h` – Heap object
- `timeout` – Timeout period

`sys_port_trace_k_heap_alloc_exit(h, timeout, ret)`

Trace Heap alloc exit.

**Parameters**

- `h` – Heap object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_heap_free(h)`

Trace Heap free.

**Parameters**

- `h` – Heap object

`sys_port_trace_k_heap_sys_k_aligned_alloc_enter(heap)`

Trace System Heap aligned alloc enter.

**Parameters**

- `heap` – Heap object

`sys_port_trace_k_heap_sys_k_aligned_alloc_exit(heap, ret)`

Trace System Heap aligned alloc exit.

**Parameters**

- `heap` – Heap object
- `ret` – Return value

`sys_port_trace_k_heap_sys_k_malloc_enter(heap)`

Trace System Heap aligned alloc enter.

**Parameters**

- `heap` – Heap object

`sys_port_trace_k_heap_sys_k_malloc_exit(heap, ret)`

Trace System Heap aligned alloc exit.

**Parameters**

- `heap` – Heap object
- `ret` – Return value

`sys_port_trace_k_heap_sys_k_free_enter(heap)`

Trace System Heap free entry.

**Parameters**

- `heap` – Heap object

`sys_port_trace_k_heap_sys_k_free_exit(heap)`

Trace System Heap free exit.

**Parameters**

- `heap` – Heap object

`sys_port_trace_k_heap_sys_k_calloc_enter(heap)`

Trace System heap calloc enter.

**Parameters**

- `heap` –

`sys_port_trace_k_heap_sys_k_calloc_exit(heap, ret)`

Trace System heap calloc exit.

**Parameters**

- `heap` – Heap object
- `ret` – Return value

## Memory Slabs

*group* `mslab_tracing_apis`

Memory Slab Tracing APIs.

### Defines

`sys_port_trace_k_mem_slab_init(slab, rc)`

Trace initialization of Memory Slab.

**Parameters**

- `slab` – Memory Slab object
- `rc` – Return value

`sys_port_trace_k_mem_slab_alloc_enter(slab, timeout)`

Trace Memory Slab alloc attempt entry.

**Parameters**

- `slab` – Memory Slab object
- `timeout` – Timeout period

`sys_port_trace_k_mem_slab_alloc_blocking(slab, timeout)`

Trace Memory Slab alloc attempt blocking.

**Parameters**

- `slab` – Memory Slab object
- `timeout` – Timeout period

`sys_port_trace_k_mem_slab_alloc_exit(slab, timeout, ret)`

Trace Memory Slab alloc attempt outcome.

**Parameters**

- `slab` – Memory Slab object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_mem_slab_free_enter(slab)`

Trace Memory Slab free entry.

**Parameters**

- `slab` – Memory Slab object

`sys_port_trace_k_mem_slab_free_exit(slab)`

Trace Memory Slab free exit.

**Parameters**

- `slab` – Memory Slab object

## Timers

*group* `timer_tracing_apis`

Timer Tracing APIs.

## Defines

`sys_port_trace_k_timer_init(timer)`

Trace initialization of Timer.

**Parameters**

- `timer` – Timer object

`sys_port_trace_k_timer_start(timer)`

Trace Timer start.

**Parameters**

- `timer` – Timer object

`sys_port_trace_k_timer_stop(timer)`

Trace Timer stop.

**Parameters**

- `timer` – Timer object

```
sys_port_trace_k_timer_status_sync_enter(timer)
```

Trace Timer status sync entry.

#### Parameters

- `timer` – Timer object

```
sys_port_trace_k_timer_status_sync_blocking(timer, timeout)
```

Trace Timer Status sync blocking.

#### Parameters

- `timer` – Timer object
- `timeout` – Timeout period

```
sys_port_trace_k_timer_status_sync_exit(timer, result)
```

Trace Time Status sync outcome.

#### Parameters

- `timer` – Timer object
- `result` – Return value

## 8.10 Device Management

### 8.10.1 MCUmgr

#### Overview

The management subsystem allows remote management of Zephyr-enabled devices. The following management operations are available:

- Image management
- File System management
- Log management (currently disabled)
- OS management
- Shell management

over the following transports:

- BLE (Bluetooth Low Energy)
- Serial (UART)
- UDP over IP

The management subsystem is based on the Simple Management Protocol (SMP) provided by [MCUmgr](#), an open source project that provides a management subsystem that is portable across multiple real-time operating systems.

The management subsystem is split in two different locations in the Zephyr tree:

- [zephyrproject-rtos/mcumgr repo](#) contains a clean import of the MCUmgr project
- [subsys/mgmt/](#) contains the Zephyr-specific bindings to MCUmgr

Additionally there is a sample that provides management functionality over BLE and serial.

## Command-line Tool

MCUmgr provides a command-line tool, `mcumgr`, for managing remote devices. The tool is written in the Go programming language.

To install the tool:

```
go get github.com/apache/mynext-mcumgr-cli/mcumgr
```

## Configuring the transport

There are two command-line options that are responsible for setting and configuring the transport layer to use when communicating with managed device:

- `--conntype` is used to choose the transport used, and
- `--connstring` is used to pass a comma separated list of options in the key=value format, where each valid key depends on the particular conntype.

Valid transports for `--conntype` are `serial`, `ble` and `udp`. Each transport expects a different set of key/value options:

`serial`

`--connstring` accepts the following key values:

<code>dev</code>	the device name for the OS mcumgr is running on (eg, <code>/dev/ttyUSB0</code> , <code>/dev/tty.usbserial</code> , <code>COM1</code> , etc).
<code>baud</code>	the communication speed; must match the baudrate of the server.
<code>mtu</code>	aka Maximum Transmission Unit, the maximum protocol packet size.

`ble`

`--connstring` accepts the following key values:

<code>ctrl_name</code>	an OS specific string for the controller name.
<code>own_addr_type</code>	can be one of <code>public</code> , <code>random</code> , <code>rpa_pub</code> , <code>rpa_rnd</code> , where <code>random</code> is the default.
<code>peer_name</code>	the name the peer BLE device advertises, this should match the configuration specified with <code>:kconfig: 'CONFIG_BT_DEVICE_NAME'</code> .
<code>peer_id</code>	the peer BLE device address or UUID. Only required when <code>peer_name</code> was not given. The format depends on the OS where mcumgr is run, it is a 6 bytes hexadecimal string separated by colons on Linux, or a 128-bit UUID on macOS.
<code>conn_timeout</code>	a float number representing the connection timeout in seconds.

`udp`

`--connstring` takes the form `[addr]:port` where:

<code>addr</code>	can be a DNS name (if it can be resolved to the device IP), IPv4 addr (app must be built with <code>:kconfig: 'CONFIG_MCUMGR_SMP_UDP_IPV4'</code> ), or IPv6 addr (app must be built with <code>:kconfig: 'CONFIG_MCUMGR_SMP_UDP_IPV6'</code> )
<code>port</code>	any valid UDP port.

## Saving the connection config

The transport configuration can be managed with the `conn` sub-command and later used with `--conn` (or `-c`) parameter to skip typing both `--conntype` and `--connstring`. For example a new config for a serial device that would require typing `mcumgr --conntype serial --connstring dev=/dev/ttyACM0,baud=115200,mtu=512` can be saved with:

```
mcumgr conn add acm0 type="serial" connstring="dev=/dev/ttyACM0,baud=115200,mtu=512"
```

Accessing this port can now be done with:

```
mcumgr -c acm0
```

## General options

Some options work for every `mcumgr` command and might be helpful to debug and fix issues with the communication, among them the following deserve special mention:

<code>-l</code> <log-level>	Configures the log level, which can be one of <code>critical</code> , <code>error</code> , <code>warn</code> , <code>info</code> or <code>debug</code> , from less to most verbose. When there are communication issues, <code>-lDEBUG</code> might be useful to dump the packets for later inspection.
<code>-t</code> <timeout>	Changes the timeout waiting for a response from the default of 10s to a given value. Some commands might take a long time of processing, eg, the erase before an image upload, and might need incrementing the timeout to a larger value.
<code>-r</code> <tries>	Changes the number of retries on timeout from the default of 1 to a given value.

## List of Commands

Not all commands defined by `mcumgr` (and SMP protocol) are currently supported on Zephyr. The ones that are supported are described in the following table:

**Tip:** Running `mcumgr` with no parameters, or `-h` will display the list of commands.

Command	Description
<code>echo</code>	Send data to a device and display the echoed back data. This command is part of the OS group, which must be enabled by setting <code>:kconfig:'CONFIG_MCUMGR_CMD_OS_MGMT'</code> . The <code>echo</code> command itself can be enabled by setting <code>:kconfig:'CONFIG_OS_MGMT_ECHO'</code> .
<code>fs</code>	Access files on a device. More info in <a href="#">Filesystem Management</a> .
<code>image</code>	Manage images on a device. More info in <a href="#">Image Management</a> .
<code>reset</code>	Perform a soft reset of a device. This command is part of the OS group, which must be enabled by setting <code>:kconfig:'CONFIG_MCUMGR_CMD_OS_MGMT'</code> . The <code>reset</code> command itself is always enabled and the time taken for a reset to happen can be set with <code>:kconfig:'CONFIG_OS_MGMT_RESET_MS'</code> (in ms).
<code>shell</code>	Execute a command in the remote shell. This option is disabled by default and can be enabled with <code>:kconfig:'CONFIG_MCUMGR_CMD_SHELL_MGMT' = y</code> . To know more about the shell in Zephyr check <a href="#">Shell</a> .
<code>stat</code>	Read statistics from a device. More info in <a href="#">Statistics Management</a> .
<code>taskstat</code>	Read task statistics from a device. This command is part of the OS group, which must be enabled by setting <code>:kconfig:'CONFIG_MCUMGR_CMD_OS_MGMT'</code> . The <code>taskstat</code> command itself can be enabled by setting <code>:kconfig:'CONFIG_OS_MGMT_TASKSTAT'</code> . <code>:kconfig:'CONFIG_THREAD_MONITOR'</code> also needs to be enabled otherwise a <code>-8 (MGMT_ERR_ENOTSUP)</code> will be returned.

**Tip:** `taskstat` has a few options that might require tweaking. The `:kcon-`

**fig:** `CONFIG_THREAD_NAME` must be set to display the task names, otherwise the priority is displayed. Since the taskstat packets are large, they might need increasing the **:kconfig:** `CONFIG_MCUMGR_BUF_SIZE` option.

**Warning:** To display the correct stack size in the taskstat command, the **:kconfig:** `CONFIG_THREAD_STACK_INFO` option must be set. To display the correct stack usage in the taskstat command, both **:kconfig:** `CONFIG_THREAD_STACK_INFO` and **:kconfig:** `CONFIG_INIT_STACKS` options must be set.

## Image Management

The image management provided by mcumgr is based on the image format defined by MCUboot. For more details on the internals see [MCUboot design](#) and [Signing Binaries](#).

To list available images in a device:

```
mcumgr <connection-options> image list
```

This should result in an output similar to this:

```
$ mcumgr -c acm0 image list
Images:
  image=0 slot=0
    version: 1.0.0
    bootable: true
    flags: active confirmed
    hash: 86dca73a3439112b310b5e033d811ec2df728d2264265f2046fced5a9ed00cc7
Split status: N/A (0)
```

Where image is the number of the image pair in a multi-image system, and slot is the number of the slot where the image is stored, 0 for primary and 1 for secondary. This image being active and confirmed means it will run again on next reset. Also relevant is the hash, which is used by other commands to refer to this specific image when performing operations.

An image can be manually erased using:

```
mcumgr <connection-options> image erase
```

The behavior of erase is defined by the server (mcumgr in the device). The current implementation is limited to erasing the image in the secondary partition.

To upload a new image:

```
mcumgr <connection-options> image upload [-n] [-e] [-u] <signed-bin>
```

- `-n`: This option allows uploading a new image to a specific set of images in a multi-image system, and is currently only supported by MCUboot when the `CONFIG_MCUBOOT_SERIAL` option is enabled.
- `-e`: This option avoids performing a full erase of the partition before starting a new upload.

**Tip:** The `-e` option should always be passed in because the upload command already checks if an erase is required, respecting the **:kconfig:** `CONFIG_IMG_ERASE_PROGRESSIVELY` setting.

**Tip:** If the upload command times out while waiting for a response from the device, `-t` might be used to increase the wait time to something larger than the default of 10s. See [general\\_options](#).

---

**Warning:** `mcumgr` does not understand `.hex` files, when uploading a new image always use the `.bin` file.

- `-u`: upgrade only to newer image version.

After an image upload is finished, a new `image list` would now have an output like this:

```
$ mcumgr -c acm0 image upload -e build/zephyr/zephyr.signed.bin
35.69 KiB / 92.92 KiB [=====>-----] 38.41% 2.97 KiB/s 00m19
```

Now listing the images again:

```
$ mcumgr -c acm0 image list
Images:
image=0 slot=0
  version: 1.0.0
  bootable: true
  flags: active confirmed
  hash: 86dca73a3439112b310b5e033d811ec2df728d2264265f2046fced5a9ed00cc7
image=0 slot=1
  version: 1.1.0
  bootable: true
  flags:
  hash: e8cf0dcef3ec8addee07e8c4d5dc89e64ba3fae46a2c5267fc4efbea4ca0e9f4
Split status: N/A (0)
```

To test a new upgrade image the `test` command is used:

```
mcumgr <connection-options> image test <hash>
```

This command should mark a test upgrade, which means that after the next reboot the bootloader will execute the upgrade and jump into the new image. If no other image operations are executed on the newly running image, it will revert back to the image that was previously running on the device on the subsequent reset. When a test is requested, flags will be updated with pending to inform that a new image will be run after a reset:

```
$ mcumgr -c acm0 image test
↪e8cf0dcef3ec8addee07e8c4d5dc89e64ba3fae46a2c5267fc4efbea4ca0e9f4
Images:
image=0 slot=0
  version: 1.0.0
  bootable: true
  flags: active confirmed
  hash: 86dca73a3439112b310b5e033d811ec2df728d2264265f2046fced5a9ed00cc7
image=0 slot=1
  version: 1.1.0
  bootable: true
  flags: pending
  hash: e8cf0dcef3ec8addee07e8c4d5dc89e64ba3fae46a2c5267fc4efbea4ca0e9f4
Split status: N/A (0)
```

After a reset the output with change to:

```
$ mcumgr -c acm0 image list
Images:
image=0 slot=0
  version: 1.1.0
  bootable: true
  flags: active
  hash: e8cf0dcef3ec8addee07e8c4d5dc89e64ba3fae46a2c5267fc4efbea4ca0e9f4
image=0 slot=1
  version: 1.0.0
  bootable: true
  flags: confirmed
  hash: 86dca73a3439112b310b5e033d811ec2df728d2264265f2046fced5a9ed00cc7
Split status: N/A (0)
```

**Tip:** It's important to mention that an upgrade only ever happens if the image is valid. The first thing MCUBoot does when an upgrade is requested is to validate the image, using the SHA-256 and/or the signature (depending on the configuration). So before uploading an image, one way to be sure it is valid is to run `imgtool verify -k <your-signature-key> <your-image>`, where `-k <your-signature-key>` can be skipped if no signature validation was enabled.

The confirmed flag in the secondary slot tells that after the next reset a revert upgrade will be performed to switch back to the original layout.

The command used to confirm that an image is OK and no revert should happen (no hash required) is:

```
mcumgr <connection-options> image confirm [hash]
```

The confirm command can also be run passing in a hash so that instead of doing a test/revert procedure, the image in the secondary partition is directly upgraded to.

**Tip:** The whole test/revert cycle does not need to be done using only the `mcumgr` command-line tool. A better alternative is to perform a test and allow the new running image to self-confirm after any checks by calling `boot_write_img_confirmed()`.

**Tip:** The maximum size of a chunk communicated between the client and server is set with `:kconfig: `CONFIG_IMG_MGMT_UL_CHUNK_SIZE``. The default is 512 but can be decreased for systems with low amount of RAM down to 128. When this value is changed, the mtu of the port must be smaller than or equal to this value.

**Tip:** Building with `:kconfig: `CONFIG_IMG_MGMT_VERBOSE_ERR`` enables better error messages when failures happen (but increases the application size).

## Statistics Management

Statistics are used for troubleshooting, maintenance, and usage monitoring; it consists basically of user-defined counters which are tightly connected to `mcumgr` and can be used to track any information for easy retrieval. The available sub-commands are:

```
mcumgr <connection-options> stat list
mcumgr <connection-options> stat <section-name>
```

Statistics are organized in sections (also called groups), and each section can be individually queried. Defining new statistics sections is done by using macros available under `<stats/stats.h>`. Each section consists of multiple variables (or counters), all with the same size (16, 32 or 64 bits).

To create a new section `my_stats`:

```
STATS_SECT_START(my_stats)
    STATS_SECT_ENTRY(my_stat_counter1)
    STATS_SECT_ENTRY(my_stat_counter2)
    STATS_SECT_ENTRY(my_stat_counter3)
STATS_SECT_END;

STATS_SECT_DECL(my_stats) my_stats;
```

Each entry can be declared with `STATS_SECT_ENTRY` (or the equivalent `STATS_SECT_ENTRY32`), `STATS_SECT_ENTRY16` or `STATS_SECT_ENTRY64`. All statistics in a section must be declared with the same size.

The statistics counters can either have names or not, depending on the setting of the **`:kconfig: `CONFIG_STATS_NAMES``** option. Using names requires an extra declaration step:

```
STATS_NAME_START(my_stats)
    STATS_NAME(my_stats, my_stat_counter1)
    STATS_NAME(my_stats, my_stat_counter2)
    STATS_NAME(my_stats, my_stat_counter3)
STATS_NAME_END(my_stats);
```

---

**Tip:** Disabling **`:kconfig: `CONFIG_STATS_NAMES``** will free resources. When this option is disabled the `STATS_NAME*` macros output nothing, so adding them in the code does not increase the binary size.

---

---

**Tip:** **`:kconfig: `CONFIG_STAT_MGMT_MAX_NAME_LEN``** sets the maximum length of a section name that can be accepted as parameter for showing the section data, and might require tweaking for long section names.

---

The final steps to use a statistics section is to initialize and register it:

```
rc = STATS_INIT_AND_REG(my_stats, STATS_SIZE_32, "my_stats");
assert (rc == 0);
```

In the running code a statistics counter can be incremented by 1 using `STATS_INC`, by N using `STATS_INCN` or reset with `STATS_CLEAR`.

Let's suppose we want to increment those counters by 1, 2 and 3 every second. To get a list of stats:

```
$ mcumgr --conn acm0 stat list
stat groups:
    my_stats
```

To get the current value of the counters in `my_stats`:

```
$ mcumgr --conn acm0 stat my_stats
stat group: my_stats
    13 my_stat_counter1
    26 my_stat_counter2
    39 my_stat_counter3

$ mcumgr --conn acm0 stat my_stats
```

(continues on next page)

(continued from previous page)

```
stat group: my_stats
    16 my_stat_counter1
    32 my_stat_counter2
    48 my_stat_counter3
```

When `:kconfig: `CONFIG_STATS_NAMES`` is disabled the output will look like this:

```
$ mcumgr --conn acm0 stat my_stats
stat group: my_stats
    8 s0
   16 s1
   24 s2
```

## Filesystem Management

The filesystem module is disabled by default due to security concerns: because of a lack of access control every file in the FS will be accessible, including secrets, etc. To enable it `:kconfig: `CONFIG_MCUMGR_CMD_FS_MGMT`` must be set (y). Once enabled the following sub-commands can be used:

```
mcumgr <connection-options> fs download <remote-file> <local-file>
mcumgr <connection-options> fs upload <local-file> <remote-file>
```

Using the `fs` command, requires `:kconfig: `CONFIG_FILE_SYSTEM`` to be enabled, and that some particular filesystem is enabled and properly mounted by the running application, eg for `littefs` this would mean enabling `:kconfig: `CONFIG_FILE_SYSTEM_LITTLEFS``, defining a storage partition *Flash map* and mounting the filesystem in the startup (`fs_mount()`).

Uploading a new file to a `littlefs` storage, mounted under `/lfs`, can be done with:

```
$ mcumgr -c acm0 fs upload foo.txt /lfs/foo.txt
25
Done
```

Where 25 is the size of the file.

For downloading a file, let's first use the `fs` command (`:kconfig: `CONFIG_FILE_SYSTEM_SHELL`` must be enabled) in a remote shell to create a new file:

```
uart:~$ fs write /lfs/bar.txt 41 42 43 44 31 32 33 34 0a
uart:~$ fs read /lfs/bar.txt
File size: 9
00000000  41 42 43 44 31 32 33 34 0A                ABCD1234.
```

Now it can be downloaded using:

```
$ mcumgr -c acm0 fs download /lfs/bar.txt bar.txt
0
9
Done
$ cat bar.txt
ABCD1234
```

Where 0 is the return code, and 9 is the size of the file.

**Warning:** The commands might exhaust the system workqueue, if its size is not large enough, so increasing `:kconfig: `CONFIG_SYSTEM_WORKQUEUE_STACK_SIZE`` might be required for correct behavior.

The size of the stack allocated buffer used to store the blocks, while transferring a file can be adjusted with `:kconfig: `CONFIG_FS_MGMT_DL_CHUNK_SIZE``; this allows saving RAM resources.

**Tip:** `:kconfig: `CONFIG_FS_MGMT_PATH_SIZE`` sets the maximum PATH accepted for a file name. It might require tweaking for longer file names.

---

## Bootloader integration

The *Device Firmware Upgrade* subsystem integrates the management subsystem with the bootloader, providing the ability to send and upgrade a Zephyr image to a device.

Currently only the MCUboot bootloader is supported. See *MCUboot* for more information.

### 8.10.2 Device Firmware Upgrade

#### Overview

The Device Firmware Upgrade subsystem provides the necessary frameworks to upgrade the image of a Zephyr-based application at run time. It currently consists of two different modules:

- `subsys/dfu/boot/`: Interface code to bootloaders
- `subsys/dfu/img_util/`: Image management code

The DFU subsystem deals with image management, but not with the transport or management protocols themselves required to send the image to the target device. For information on these protocols and frameworks please refer to the *Device Management* section.

#### Bootloaders

**MCUboot** Zephyr is directly compatible with the open source, cross-RTOS *MCUboot boot loader*. It interfaces with MCUboot and is aware of the image format required by it, so that Device Firmware Upgrade is available when MCUboot is the boot loader used with Zephyr. The source code itself is hosted in the *MCUboot GitHub Project* page.

In order to use MCUboot with Zephyr you need to take the following into account:

1. You will need to define the flash partitions required by MCUboot; see *Flash map* for details.
2. Your application's `.conf` file needs to enable the `:kconfig: `CONFIG_BOOTLOADER_MCUBOOT`` Kconfig option in order for Zephyr to be built in an MCUboot-compatible manner
3. You need to build and flash MCUboot itself on your device
4. You might need to take precautions to avoid mass erasing the flash and also to flash the Zephyr application image at the correct offset (right after the bootloader)

More detailed information regarding the use of MCUboot with Zephyr can be found in the *MCUboot with Zephyr* documentation page on the MCUboot website.

## 8.11 Devicetree Guide

This is a high-level guide to devicetree as it is used for Zephyr development. See [Devicetree](#) for reference material.

### 8.11.1 Introduction to devicetree

---

**Tip:** This is a conceptual overview of devicetree and how Zephyr uses it. For step-by-step guides and examples, see [Devicetree HOWTOs](#).

---

A *devicetree* is a hierarchical data structure that describes hardware. The [Devicetree specification](#) defines its source and binary representations. Zephyr uses devicetree to describe the hardware available on its boards, as well as that hardware's initial configuration.

There are two types of devicetree input files: *devicetree sources* and *devicetree bindings*. The sources contain the devicetree itself. The bindings describe its contents, including data types. The [build system](#) uses devicetree sources and bindings to produce a generated C header. The generated header's contents are abstracted by the `devicetree.h` API, which you can use to get information from your devicetree.

Here is a simplified view of the process:

Fig. 5: Devicetree build flow

All Zephyr and application source code files can include and use `devicetree.h`. This includes [device drivers](#), [applications](#), [tests](#), the kernel, etc.

The API itself is based on C macros. The macro names all start with `DT_`. In general, if you see a macro that starts with `DT_` in a Zephyr source file, it's probably a `devicetree.h` macro. The generated C header contains macros that start with `DT_` as well; you might see those in compiler error messages. You always can tell a generated- from a non-generated macro: generated macros have some lowercased letters, while the `devicetree.h` macro names have all capital letters.

Some information defined in devicetree is available via `CONFIG_` macros generated from [Kconfig](#). This is often done for backwards compatibility, since Zephyr has used Kconfig for longer than devicetree, and is still in the process of converting some information from Kconfig to devicetree. It is also done to allow Kconfig overrides of default values taken from devicetree. Devicetree information is referenced from Kconfig via [Kconfig functions](#). See [Devicetree versus Kconfig](#) for some additional comparisons with Kconfig.

#### Syntax and structure

As the name indicates, a devicetree is a tree. The human-readable text format for this tree is called DTS (for devicetree source), and is defined in the [Devicetree specification](#).

Here is an example DTS file:

```

/dts-v1/;

/ {
    a-node {
        subnode_label: a-sub-node {
            foo = <3>;
        };
    };
};

```

The `/dts-v1/;` line means the file's contents are in version 1 of the DTS syntax, which has replaced a now-obsolete "version 0".

The tree has three *nodes*:

1. A root node: `/`
2. A node named `a-node`, which is a child of the root node
3. A node named `a-sub-node`, which is a child of `a-node`

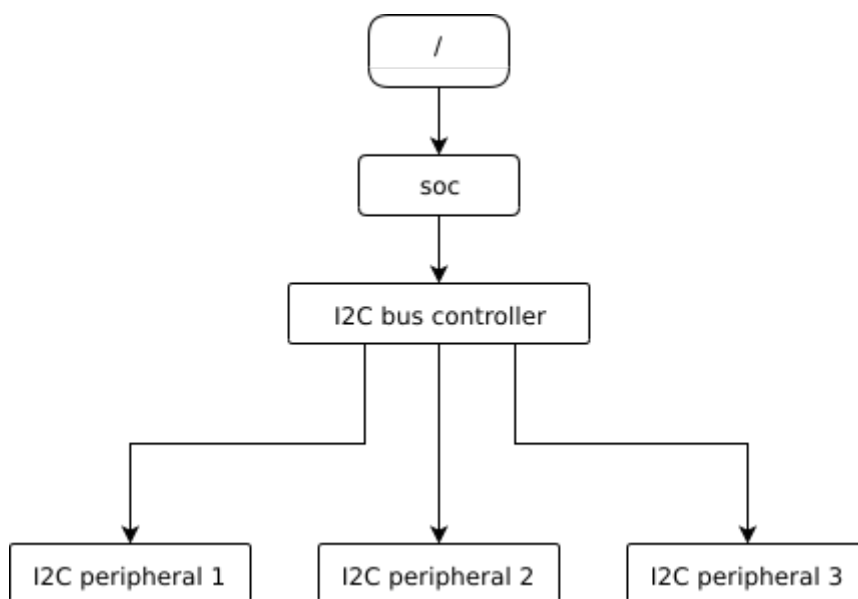

Nodes can be given *labels*, which are unique shorthands that can be used to refer to the labeled node elsewhere in the devicetree. Above, `a-sub-node` has label `subnode_label`. A node can have zero, one, or multiple node labels.

Devicetree nodes have *paths* identifying their locations in the tree. Like Unix file system paths, devicetree paths are strings separated by slashes (`/`), and the root node's path is a single slash: `/`. Otherwise, each node's path is formed by concatenating the node's ancestors' names with the node's own name, separated by slashes. For example, the full path to `a-sub-node` is `/a-node/a-sub-node`.

Devicetree nodes can also have *properties*. Properties are name/value pairs. Property values can be any sequence of bytes. In some cases, the values are an array of what are called *cells*. A cell is just a 32-bit unsigned integer.

Node `a-sub-node` has a property named `foo`, whose value is a cell with value 3. The size and type of `foo`'s value are implied by the enclosing angle brackets (`<` and `>`) in the DTS. See [Writing property values](#) below for more example property values.

In practice, devicetree nodes usually correspond to some hardware, and the node hierarchy reflects the hardware's physical layout. For example, let's consider a board with three I2C peripherals connected to an I2C bus controller on an SoC, like this:

Nodes corresponding to the I2C bus controller and each I2C peripheral would be present in the device-tree. Reflecting the hardware layout, the I2C peripheral nodes would be children of the bus controller node. Similar conventions exist for representing other types of hardware.

The DTS would look something like this:

```
/dts-v1/;

/ {
    soc {
        i2c-bus-controller {
            i2c-peripheral-1 {
            };
            i2c-peripheral-2 {
            };
            i2c-peripheral-3 {
            };
        };
    };
};
```

Properties are used in practice to describe or configure the hardware the node represents. For example, an I2C peripheral's node has a property whose value is the peripheral's address on the bus.

Here's a tree representing the same example, but with real-world node names and properties you might see when working with I2C devices.

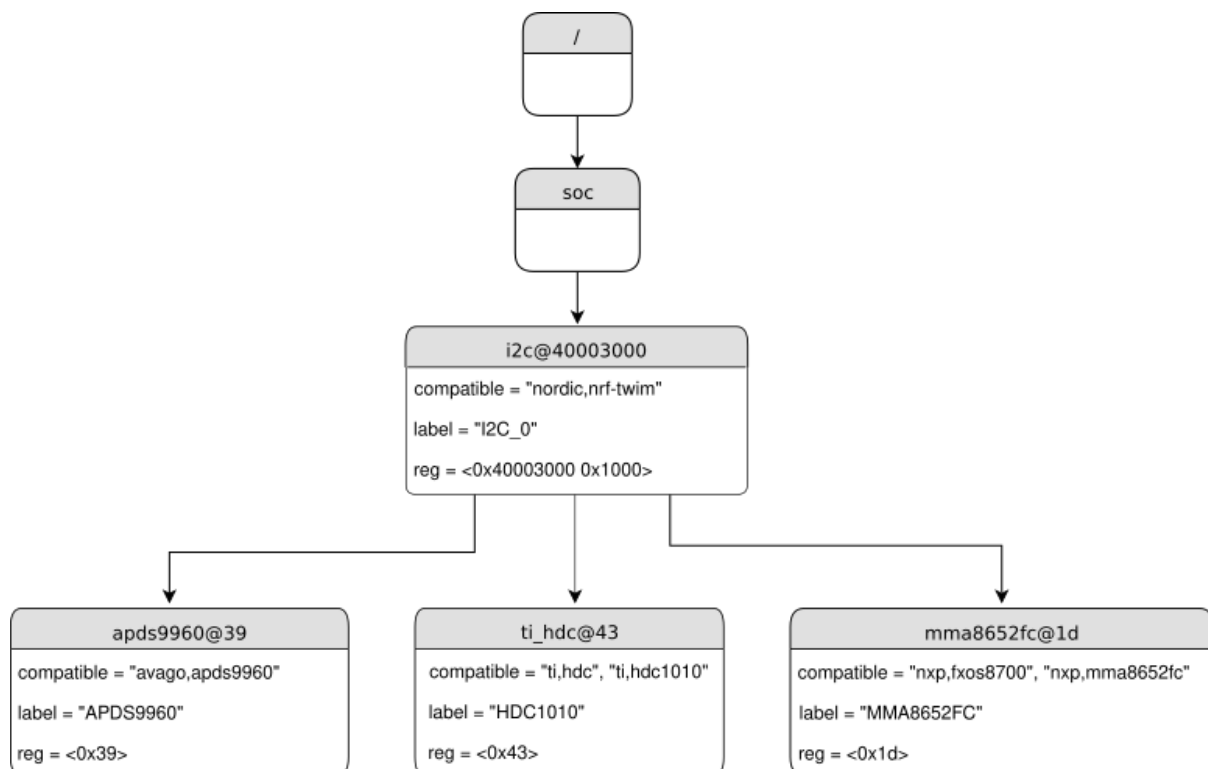

Fig. 6: I2C devicetree example with real-world names and properties. Node names are at the top of each node with a gray background. Properties are shown as “name=value” lines.

This is the corresponding DTS:

```
/dts-v1/;
```

(continues on next page)

(continued from previous page)

```

/ {
    soc {
        i2c@40003000 {
            compatible = "nordic,nrf-twim";
            label = "I2C_0";
            reg = <0x40003000 0x1000>;

            apds9960@39 {
                compatible = "avago,apds9960";
                label = "APDS9960";
                reg = <0x39>;
            };
            ti_hdc@43 {
                compatible = "ti,hdc", "ti,hdc1010";
                label = "HDC1010";
                reg = <0x43>;
            };
            mma8652fc@1d {
                compatible = "nxp,fxos8700", "nxp,mma8652fc";
                label = "MMA8652FC";
                reg = <0x1d>;
            };
        };
    };
};

```

In addition to showing more realistic names and properties, the above example introduces a new devicetree concept: unit addresses. Unit addresses are the parts of node names after an “at” sign (@), like 40003000 in `i2c@40003000`, or 39 in `apds9960@39`. Unit addresses are optional: the `soc` node does not have one.

Some more details about unit addresses and important properties follow.

### Unit address examples

In devicetree, unit addresses give a node’s address in the address space of its parent node. Here are some example unit addresses for different types of hardware.

**Memory-mapped peripherals** The peripheral’s register map base address. For example, the node named `i2c@40003000` represents an I2C controller whose register map base address is 0x40003000.

**I2C peripherals** The peripheral’s address on the I2C bus. For example, the child node `apds9960@39` of the I2C controller in the previous section has I2C address 0x39.

**SPI peripherals** An index representing the peripheral’s chip select line number. (If there is no chip select line, 0 is used.)

**Memory** The physical start address. For example, a node named `memory@2000000` represents RAM starting at physical address 0x2000000.

**Memory-mapped flash** Like RAM, the physical start address. For example, a node named `flash@8000000` represents a flash device whose physical start address is 0x8000000.

**Fixed flash partitions** This applies when the devicetree is used to store a flash partition table. The unit address is the partition’s start offset within the flash memory. For example, take this flash device and its partitions:

```

flash@8000000 {
    /* ... */

```

(continues on next page)

(continued from previous page)

```

partitions {
    partition@0 { /* ... */ };
    partition@20000 { /* ... */ };
    /* ... */
};
};

```

The node named `partition@0` has offset 0 from the start of its flash device, so its base address is 0x8000000. Similarly, the base address of the node named `partition@20000` is 0x8020000.

## Important properties

Some important properties are:

**compatible** The name of the hardware device the node represents.

The recommended format is "vendor,device", like "avago,apds9960", or a sequence of these, like "ti,hdc", "ti,hdc1010". The vendor part is an abbreviated name of the vendor. The file [dts/bindings/vendor-prefixes.txt](#) contains a list of commonly accepted vendor names. The device part is usually taken from the datasheet.

It is also sometimes a value like `gpio-keys`, `mmio-sram`, or `fixed-clock` when the hardware's behavior is generic.

The build system uses the compatible property to find the right [bindings](#) for the node. Device drivers use `devicetree.h` to find nodes with relevant compatibles, in order to determine the available hardware to manage.

The compatible property can have multiple values. Additional values are useful when the device is a specific instance of a more general family, to allow the system to match from most- to least-specific device drivers.

Within Zephyr's bindings syntax, this property has type `string-array`.

**label** The device's name according to Zephyr's [Device Driver Model](#). The value can be passed to [device\\_get\\_binding\(\)](#) to retrieve the corresponding driver-level `struct device*`. This pointer can then be passed to the correct driver API by application code to interact with the device. For example, calling `device_get_binding("I2C_0")` would return a pointer to a device structure which could be passed to [I2C API](#) functions like [i2c\\_transfer\(\)](#). The generated C header will also contain a macro which expands to this string.

**reg** Information used to address the device. The value is specific to the device (i.e. is different depending on the compatible property).

The `reg` property is a sequence of (address, length) pairs. Each pair is called a "register block". Here are some common patterns:

- Devices accessed via memory-mapped I/O registers (like `i2c@40003000`): address is usually the base address of the I/O register space, and length is the number of bytes occupied by the registers.
- I2C devices (like `apds9960@39` and its siblings): address is a slave address on the I2C bus. There is no length value.
- SPI devices: address is a chip select line number; there is no length.

You may notice some similarities between the `reg` property and common unit addresses described above. This is not a coincidence. The `reg` property can be seen as a more detailed view of the addressable resources within a device than its unit address.

**status** A string which describes whether the node is enabled.

The devicetree specification allows this property to have values "okay", "disabled", "reserved", "fail", and "fail-sss". Only the values "okay" and "disabled" are currently relevant to Zephyr; use of other values currently results in undefined behavior.

A node is considered enabled if its status property is either "okay" or not defined (i.e. does not exist in the devicetree source). Nodes with status "disabled" are explicitly disabled. (For backwards compatibility, the value "ok" is treated the same as "okay", but this usage is deprecated.) Devicetree nodes which correspond to physical devices must be enabled for the corresponding struct device in the Zephyr driver model to be allocated and initialized.

**interrupts** Information about interrupts generated by the device, encoded as an array of one or more *interrupt specifiers*. Each interrupt specifier has some number of cells. See section 2.4, *Interrupts and Interrupt Mapping*, in the [Devicetree Specification release v0.3](#) for more details.

Zephyr's devicetree bindings language lets you give a name to each cell in an interrupt specifier.

## Writing property values

This section describes how to write property values in DTS format. The property types in the table below are described in detail in [Devicetree bindings](#).

Some specifics are skipped in the interest of keeping things simple; if you're curious about details, see the devicetree specification.

Property type	How to write	Example
string	Double quoted	<code>a-string = "hello, world!";</code>
int	between angle brackets (< and >)	<code>an-int = &lt;1&gt;;</code>
boolean	for true, with no value (for false, use / delete-property/)	<code>my-true-boolean;</code>
array	between angle brackets (< and >), separated by spaces	<code>foo = &lt;0xdeadbeef 1234 0&gt;;</code>
uint8-array	in hexadecimal <i>without</i> leading 0x, between square brackets ([ and ]).	<code>a-byte-array = [00 01 ab];</code>
string-array	separated by commas	<code>a-string-array = "string one", "string two", "string three";</code>
phandle	between angle brackets (< and >)	<code>a-phandle = &lt;&amp;mynode&gt;;</code>
phan-dles	between angle brackets (< and >), separated by spaces	<code>some-phandles = &lt;&amp;mynode0 &amp;mynode1 &amp;mynode2&gt;;</code>
phandle-array	between angle brackets (< and >), separated by spaces	<code>a-phandle-array = &lt;&amp;mynode0 1 2 &amp;mynode1 3 4&gt;;</code>

Additional notes on the above:

- Boolean properties are true if present. They should not have a value. A boolean property is only false if it is completely missing in the DTS.
- The `foo` property value above has three *cells* with values 0xdeadbeef, 1234, and 0, in that order. Note that hexadecimal and decimal numbers are allowed and can be intermixed. Since Zephyr transforms DTS to C sources, it is not necessary to specify the endianness of an individual cell here.
- 64-bit integers are written as two 32-bit cells in big-endian order. The value 0xaaaa0000bbbb1111 would be written `<0xaaaa0000 0xbbbb1111>`.
- The `a-byte-array` property value is the three bytes 0x00, 0x01, and 0xab, in that order.
- Parentheses, arithmetic operators, and bitwise operators are allowed. The `bar` property contains a single cell with value 64:

```
bar = <(2 * (1 << 5))>;
```

Note that the entire expression must be parenthesized.

- Property values refer to other nodes in the devicetree by their *phandles*. You can write a phandle using `&foo`, where `foo` is a [node label](#). Here is an example devicetree fragment:

```
foo: device@0 { };
device@1 {
    sibling = <&foo 1 2>;
};
```

The `sibling` property of node `device@1` contains three cells, in this order:

1. The `device@0` node's phandle, which is written here as `&foo` since the `device@0` node has a node label `foo`
2. The value 1
3. The value 2

In the devicetree, a phandle value is a cell – which again is just a 32-bit unsigned int. However, the Zephyr devicetree API generally exposes these values as *node identifiers*. Node identifiers are covered in more detail in [Devicetree access from C/C++](#).

- Array and similar type property values can be split into several `<>` blocks, like this:

```
foo = <1 2>, <3 4>; // Okay for 'type: array'
foo = <&label1 &label2>, <&label3 &label4>; // Okay for 'type: handles'
foo = <&label1 1 2>, <&label2 3 4>; // Okay for 'type: handle-array'
```

This is recommended for readability when possible if the value can be logically grouped into blocks of sub-values.

## Aliases and chosen nodes

There are two additional ways beyond [node labels](#) to refer to a particular node without specifying its entire path: by alias, or by chosen node.

Here is an example devicetree which uses both:

```
/dts-v1/;

/ {
    chosen {
        zephyr,console = &uart0;
    };

    aliases {
        my-uart = &uart0;
    };

    soc {
        uart0: serial@12340000 {
            ...
        };
    };
};
```

The `/aliases` and `/chosen` nodes do not refer to an actual hardware device. Their purpose is to specify other nodes in the devicetree.

Above, `my-uart` is an alias for the node with path `/soc/serial@12340000`. Using its node label `uart0`, the same node is set as the value of the chosen `zephyr,console` node.

Zephyr sample applications sometimes use aliases to allow overriding the particular hardware device used by the application in a generic way. For example, `blinky-sample` uses this to abstract the LED to blink via the `led0` alias.

The `/chosen` node's properties are used to configure system- or subsystem-wide values. See [Chosen nodes](#) for more information.

## Input and output files

This section describes the input and output files shown in the figure at the [top of this introduction](#) in more detail.

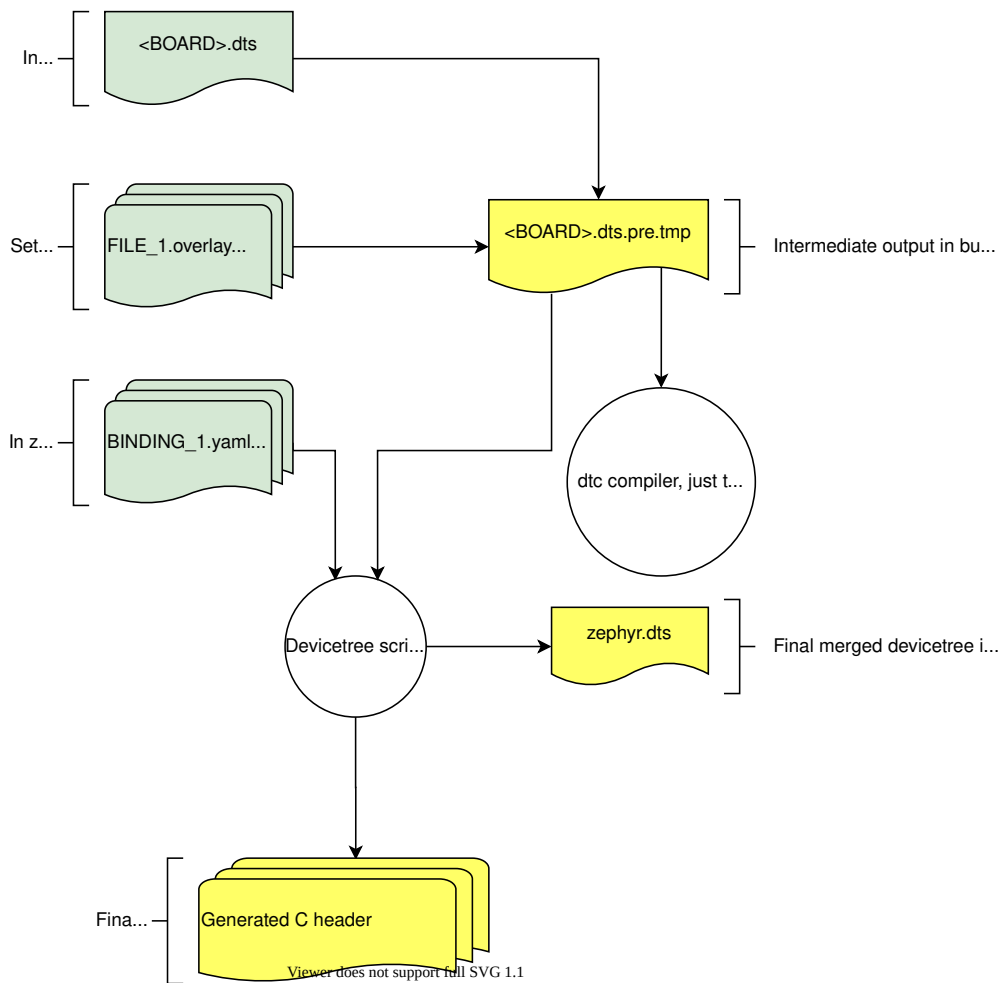

Fig. 7: DeviceTree input (green) and output (yellow) files

**Input files** There are four types of devicetree input files:

- sources (`.dts`)
- includes (`.dtsi`)
- overlays (`.overlay`)
- bindings (`.yaml`)

The devicetree files inside the `zephyr` directory look like this:

```
boards/<ARCH>/<BOARD>/<BOARD>.dts
dts/common/skeleton.dtsi
dts/<ARCH>/.../<SOC>.dtsi
dts/bindings/.../binding.yaml
```

Generally speaking, every supported board has a `BOARD.dts` file describing its hardware. For example, the `reel_board` has [boards/arm/reel\\_board/reel\\_board.dts](#).

`BOARD.dts` includes one or more `.dtsi` files. These `.dtsi` files describe the CPU or system-on-chip Zephyr runs on, perhaps by including other `.dtsi` files. They can also describe other common hardware features shared by multiple boards. In addition to these includes, `BOARD.dts` also describes the board's specific hardware.

The `dts/common` directory contains `skeleton.dtsi`, a minimal include file for defining a complete devicetree. Architecture-specific subdirectories (`dts/<ARCH>`) contain `.dtsi` files for CPUs or SoCs which extend `skeleton.dtsi`.

The C preprocessor is run on all devicetree files to expand macro references, and includes are generally done with `#include <filename>` directives, even though DTS has a `/include/ "<filename>"` syntax.

`BOARD.dts` can be extended or modified using *overlays*. Overlays are also DTS files; the `.overlay` extension is just a convention which makes their purpose clear. Overlays adapt the base devicetree for different purposes:

- Zephyr applications can use overlays to enable a peripheral that is disabled by default, select a sensor on the board for an application specific purpose, etc. Along with [Configuration System \(Kconfig\)](#), this makes it possible to reconfigure the kernel and device drivers without modifying source code.
- Overlays are also used when defining [Shields](#).

The build system automatically picks up `.overlay` files stored in certain locations. It is also possible to explicitly list the overlays to include, via the `DTC_OVERLAY_FILE` CMake variable. See [Set devicetree overlays](#) for details.

The build system combines `BOARD.dts` and any `.overlay` files by concatenating them, with the overlays put last. This relies on DTS syntax which allows merging overlapping definitions of nodes in the devicetree. See [Example: FRDM-K64F and Hexiwear K64](#) for an example of how this works (in the context of `.dtsi` files, but the principle is the same for overlays). Putting the contents of the `.overlay` files last allows them to override `BOARD.dts`.

[Devicetree bindings](#) (which are YAML files) are essentially glue. They describe the contents of devicetree sources, includes, and overlays in a way that allows the build system to generate C macros usable by device drivers and applications. The `dts/bindings` directory contains bindings.

Zephyr currently uses `dts_fixup.h` files to rename macros in `devicetree_unfixed.h` to names that are currently in use by C code. The build system looks for fixup files in the `zephyr/boards/` and `zephyr/soc/` directories by default. Fixup files exist for historical reasons. New code should generally avoid them.

**Scripts and tools** The following libraries and scripts, located in `scripts/dts/`, create output files from input files. Their sources have extensive documentation.

**dtlib.py** A low-level DTS parsing library.

**edtlb.py** A library layered on top of `dtlib` that uses bindings to interpret properties and give a higher-level view of the devicetree. Uses `dtlib` to do the DTS parsing.

**gen\_defines.py** A script that uses `edtlb` to generate C preprocessor macros from the devicetree and bindings.

In addition to these, the standard `dtc` (devicetree compiler) tool is run on the final devicetree if it is installed on your system. This is just to catch errors or warnings. The output is unused. Boards may

need to pass `dtc` additional flags, e.g. for warning suppression. Board directories can contain a file named `pre_dt_board.cmake` which configures these extra flags, like this:

```
list(APPEND EXTRA_DTC_FLAGS "-Wno-simple_bus_reg")
```

**Output files** These are created in your application's build directory.

**Warning:** Don't include the header files directly. [Devicetree access from C/C++](#) explains what to do instead.

`<build>/zephyr/include/generated/devicetree_unfixed.h` The generated macros and additional comments describing the devicetree. Included by `devicetree.h`.

`<build>/zephyr/include/generated/devicetree_fixups.h` The concatenated contents of any `dt_fixup.h` files. Included by `devicetree.h`.

`<build>/zephyr/zephyr.dts` The final merged devicetree. This file is output by `gen_defines.py` as a debugging aid, and is unused otherwise.

`<build>/zephyr/<BOARD>.dts.pre.tmp` The preprocessed and concatenated DTS sources and overlays. This is an intermediate output file, which is used to create `zephyr.dts` and `devicetree_unfixed.h`.

### 8.11.2 Design goals

Zephyr's use of devicetree has evolved significantly over time, and further changes are expected. The following are the general design goals, along with specific examples about how they impact Zephyr's source code, and areas where more work remains to be done.

#### Single source for all hardware information

Zephyr shall obtain its hardware descriptions exclusively from devicetree.

#### Examples

- New device drivers shall use devicetree APIs to determine which [devices to create](#) if possible.
- In-tree sample applications shall use [aliases](#) to determine which of multiple possible generic devices of a given type will be used in the current build. For example, the `blinky-sample` uses this to determine the LED to blink.
- Boot-time pin muxing and pin control can be accomplished via devicetree.

#### Example remaining work

- Zephyr's [Test Runner \(Twister\)](#) currently use `board.yaml` files to determine the hardware supported by a board. This should be obtained from devicetree instead.
- Various device drivers currently use `Kconfig` to determine which instances of a particular compatible are enabled. This can and should be done with devicetree overlays instead.
- Board-level documentation still contains tables of hardware support which are generated and maintained by hand. This can and should be obtained from the board level devicetree instead.
- Runtime determination of `struct device` relationships should be done using information obtained from devicetree, e.g. for device power management.

## Source compatibility with other operating systems

Zephyr’s devicetree tooling is based on a generic layer which is interoperable with other devicetree users, such as the Linux kernel.

Zephyr’s binding language *semantics* can support Zephyr-specific attributes, but shall not express Zephyr-specific relationships.

### Examples

- Zephyr’s devicetree source parser, [dtlib.py](#), is source-compatible with other tools like [dtc](#) in both directions: `dtlib.py` can parse `dtc` output, and `dtc` can parse `dtlib.py` output.
- Zephyr’s “extended dtlib” library, `edtlb.py`, shall not include Zephyr-specific features. Its purpose is to provide a higher-level view of the devicetree for common elements like interrupts and buses.  
Only the high-level `gen_defines.py` script, which is built on top of `edtlb.py`, contains Zephyr-specific knowledge and features.

### Example remaining work

- Zephyr has a custom [Devicetree bindings](#) language *syntax*. While Linux’s `dtschema` does not yet meet Zephyr’s needs, we should try to follow what it is capable of representing in Zephyr’s own bindings.
- Due to inflexibility in the bindings language, Zephyr cannot support the full set of bindings supported by Linux.
- Devicetree source sharing between Zephyr and Linux is not done.

## 8.11.3 Devicetree bindings

A devicetree on its own is only half the story for describing hardware, as it is a relatively unstructured format. *Devicetree bindings* provide the other half.

A devicetree binding declares requirements on the contents of nodes, and provides semantic information about the contents of valid nodes. Zephyr devicetree bindings are YAML files in a custom format (Zephyr does not use the `dt-schema` tools used by the Linux kernel).

This page introduces bindings, describes what they do, notes where they are found, and explains their data format.

---

**Note:** See the [Bindings index](#) for reference information on bindings built in to Zephyr.

- [Inferred bindings](#)

## Introduction

Devicetree nodes are matched to bindings using their [compatible properties](#).

During the [Configuration Phase](#), the build system tries to match each node in the devicetree to a binding file. When this succeeds, the build system uses the information in the binding file both when validating the node's contents and when generating macros for the node.

**A simple example** Here is an example devicetree node:

```
/* Node in a DTS file */
bar-device {
    compatible = "foo-company,bar-device";
    num-foos = <3>;
};
```

Here is a minimal binding file which matches the node:

```
# A YAML binding matching the node

compatible: "foo-company,bar-device"

properties:
  num-foos:
    type: int
    required: true
```

The build system matches the bar-device node to its YAML binding because the node's compatible property matches the binding's compatible: line.

**What the build system does with bindings** The build system uses bindings both to validate devicetree nodes and to convert the devicetree's contents into the generated [devicetree\\_unfixed.h](#) header file.

For example, the build system would use the above binding to check that the required num-foos property is present in the bar-device node, and that its value, <3>, has the correct type.

The build system will then generate a macro for the bar-device node's num-foos property, which will expand to the integer literal 3. This macro lets you get the value of the property in C code using the API which is discussed later in this guide in [Devicetree access from C/C++](#).

For another example, the following node would cause a build error, because it has no num-foos property, and this property is marked required in the binding:

```
bad-node {
    compatible = "foo-company,bar-device";
};
```

**Other ways nodes are matched to bindings** If a node has more than one string in its `compatible` property, the build system looks for compatible bindings in the listed order and uses the first match.

Take this node as an example:

```
baz-device {
    compatible = "foo-company,baz-device", "generic-baz-device";
};
```

The `baz-device` node would get matched to a binding with a `compatible: "generic-baz-device"` line if the build system can't find a binding with a `compatible: "foo-company,baz-device"` line.

Nodes without `compatible` properties can be matched to bindings associated with their parent nodes. These are called “child bindings”. If a node describes hardware on a bus, like I2C or SPI, then the bus type is also taken into account when matching nodes to bindings. (The [Bindings file syntax](#) section below describes how to write child bindings and bus-specific bindings.)

Some special nodes without `compatible` properties are matched to [Inferred bindings](#). For these nodes, the build system generates macros based on the properties in the final devicetree.

**Where bindings are located** Binding file names usually match their `compatible:` lines. For example, the above example binding would be named `foo-company,bar-device.yaml` by convention.

The build system looks for bindings in `dtb/bindings` subdirectories of the following places:

- the zephyr repository
- your [application source directory](#)
- your [board directory](#)
- any directories in the `DTS_ROOT` CMake variable
- any [module](#) that defines a `dtb_root` in its [Build settings](#)

The build system will consider any YAML file in any of these, including in any subdirectories, when matching nodes to bindings. A file is considered YAML if its name ends with `.yaml` or `.yml`.

**Warning:** The binding files must be located somewhere inside the `dtb/bindings` subdirectory of the above places.

For example, if `my-app` is your application directory, then you must place application-specific bindings inside `my-app/dtb/bindings`. So `my-app/dtb/bindings/serial/my-company,my-serial-port.yaml` would be found, but `my-app/my-company,my-serial-port.yaml` would be ignored.

## Bindings file syntax

Zephyr bindings files are YAML files. The top-level value in the file is a mapping. A [simple example](#) is given above.

The top-level keys in the mapping look like this:

```
# A high level description of the device the binding applies to:
description: |
    This is the Vendomatic company's foo-device.

    Descriptions which span multiple lines (like this) are OK,
    and are encouraged for complex bindings.

    See https://yaml-multiline.info/ for formatting help.
```

(continues on next page)

(continued from previous page)

```
# You can include definitions from other bindings using this syntax:
include: other.yaml

# Used to match nodes to this binding as discussed above:
compatible: "manufacturer,foo-device"

properties:
  # Requirements for and descriptions of the properties that this
  # binding's nodes need to satisfy go here.

child-binding:
  # You can constrain the children of the nodes matching this binding
  # using this key.

# If the node describes bus hardware, like an SPI bus controller
# on an SoC, use 'bus:' to say which one, like this:
bus: spi

# If the node instead appears as a device on a bus, like an external
# SPI memory chip, use 'on-bus:' to say what type of bus, like this.
# Like 'compatible', this key also influences the way nodes match
# bindings.
on-bus: spi

foo-cells:
  # "Specifier" cell names for the 'foo' domain go here; example 'foo'
  # values are 'gpio', 'pwm', and 'dma'. See below for more information.
```

The following sections describe these keys in more detail:

- [Description](#)
- [Compatible](#)
- [Properties](#)
- [Child-binding](#)
- [Bus](#)
- [On-bus](#)
- [Specifier cell names \(\\*-cells\)](#)
- [Include](#)

The `include:` key usually appears early in the binding file, but it is documented last here because you need to know how the other keys work before understanding `include:`.

**Description** A free-form description of node hardware goes here. You can put links to datasheets or example nodes or properties as well.

**Compatible** This key is used to match nodes to this binding as described above. It should look like this in a binding file:

```
# Note the comma-separated vendor prefix and device name
compatible: "manufacturer,device"
```

This devicetree node would match the above binding:

```
device {
    compatible = "manufacturer,device";
};
```

Assuming no binding has compatible: "manufacturer,device-v2", it would also match this node:

```
device-2 {
    compatible = "manufacturer,device-v2", "manufacturer,device";
};
```

Each node's compatible property is tried in order. The first matching binding is used. The *on-bus* key can be used to refine the search.

If more than one binding for a compatible is found, an error is raised.

The manufacturer prefix identifies the device vendor. See [dts/bindings/vendor-prefixes.txt](#) for a list of accepted vendor prefixes. The device part is usually from the datasheet.

Some bindings apply to a generic class of devices which do not have a specific vendor. In these cases, there is no vendor prefix. One example is the `gpio-leds` compatible which is commonly used to describe board LEDs connected to GPIOs.

If more than one binding for a compatible is found, an error is raised.

**Properties** The `properties:` key describes the properties that nodes which match the binding can contain.

For example, a binding for a UART peripheral might look something like this:

```
compatible: "manufacturer,serial"

properties:
    reg:
        type: array
        description: UART peripheral MMIO register space
        required: true
    current-speed:
        type: int
        description: current baud rate
        required: true
    label:
        type: string
        description: human-readable name
        required: false
```

The properties in the following node would be validated by the above binding:

```
my-serial@deadbeef {
    compatible = "manufacturer,serial";
    reg = <0xdeadbeef 0x1000>;
    current-speed = <115200>;
    label = "UART_0";
};
```

This is used to check that required properties appear, and to control the format of output generated for them.

Except for some special properties, like `reg`, whose meaning is defined by the devicetree specification itself, only properties listed in the `properties:` key will have generated macros.

**Example property definitions** Here are some more examples.

```
properties:
    # Describes a property like 'current-speed = <115200>'. We pretend that
    # it's obligatory for the example node and set 'required: true'.
    current-speed:
        type: int
        required: true
        description: Initial baud rate for bar-device

    # Describes an optional property like 'keys = "foo", "bar";'
    keys:
        type: string-array
        required: false
        description: Keys for bar-device

    # Describes an optional property like 'maximum-speed = "full-speed";'
    # the enum specifies known values that the string property may take
    maximum-speed:
        type: string
        required: false
        description: Configures USB controllers to work up to a specific speed.
        enum:
            - "low-speed"
            - "full-speed"
            - "high-speed"
            - "super-speed"

    # Describes an optional property like 'resolution = <16>';
    # the enum specifies known values that the int property may take
    resolution:
        type: int
        required: false
        enum:
            - 8
            - 16
            - 24
            - 32

    # Describes a required property '#address-cells = <1>'; the const
    # specifies that the value for the property is expected to be the value 1
    "#address-cells":
        type: int
        required: true
        const: 1

    int-with-default:
        type: int
        required: false
        default: 123
        description: Value for int register, default is power-up configuration.

    array-with-default:
        type: array
        required: false
        default: [1, 2, 3] # Same as 'array-with-default = <1 2 3>'

    string-with-default:
```

(continues on next page)

(continued from previous page)

```

    type: string
    required: false
    default: "foo"

string-array-with-default:
    type: string-array
    required: false
    default: ["foo", "bar"] # Same as 'string-array-with-default = "foo", "bar"'

uint8-array-with-default:
    type: uint8-array
    required: false
    default: [0x12, 0x34] # Same as 'uint8-array-with-default = [12 34]'

```

**Property entry syntax** As shown by the above examples, each property entry in a binding looks like this:

```

<property name>:
    required: <true | false>
    type: <string | int | boolean | array | uint8-array | string-array |
        phandle | phandles | phandle-array | path | compound>
    deprecated: <true | false>
    default: <default>
    description: <description of the property>
    enum:
        - <item1>
        - <item2>
        ...
        - <itemN>
    const: <string | int>

```

**Required properties** If a node matches a binding but is missing any property which the binding defines with `required: true`, the build fails.

**Property types** The type of a property constrains its values. The following types are available. See [Writing property values](#) for more details about writing values of each type in a DTS file.

Type	Description	Example in DTS
string	exactly one string	label = "UART_0";
int	exactly one 32-bit value (cell)	current-speed = <115200>;
boolean	flags that don't take a value when true, and are absent if false	hw-flow-control;
array	zero or more 32-bit values (cells)	offsets = <0x100 0x200 0x300>;
uint8-array	zero or more bytes, in hex ('bytestring' in the Devicetree specification)	local-mac-address = [de ad be ef 12 34];
string-array	zero or more strings	dma-names = "tx", "rx";
phandle	exactly one phandle	interrupt-parent = <&gic>;
phandles	zero or more phandles	pinctrl-0 = <&uart2_tx_pd5 &uart2_rx_pd6>;
phandle-array	a list of phandles and 32-bit cells (usually specifiers)	dmas = <&dma0 2>, <&dma0 3>;
path	a path to a node as a phandle path reference or path string	zephyr,bt-c2h-uart = &uart0; or foo = "/path/to/some/node";
compound	a catch-all for more complex types (no macros will be generated)	foo = <&label>, [01 02];

**Deprecated properties** A property with `deprecated: true` indicates to both the user and the tooling that the property is meant to be phased out.

The tooling will report a warning if the devicetree includes the property that is flagged as deprecated. (This warning is upgraded to an error in the [Test Runner \(Twister\)](#) for upstream pull requests.)

**Default values for properties** The optional `default:` setting gives a value that will be used if the property is missing from the devicetree node.

For example, with this binding fragment:

```
properties:
  foo:
    type: int
    default: 3
```

If property `foo` is missing in a matching node, then the output will be as if `foo = <3>;` had appeared in the DTS (except YAML data types are used for the default value).

Note that it only makes sense to combine `default:` with `required: false`. Combining it with `required: true` will raise an error.

There is a risk in using `default:` when the value in the binding may be incorrect for a particular board or hardware configuration. For example, defaulting the capacity of the connected power cell in a charging IC binding is likely to be incorrect. For such properties it's better to make the property `required: true`, forcing the devicetree maintainer into an explicit and witting choice.

Driver developers should use their best judgment as to whether a value can be safely defaulted. Candidates for default values include:

- delays that would be different only under unusual conditions (such as intervening hardware)
- configuration for devices that have a standard initial configuration (such as a USB audio headset)
- defaults which match the vendor-specified power-on reset value (as long as they are independent from other properties)

Power-on reset values may be used for defaults as long as they're independent. If changing one property would require changing another to create a consistent configuration, then those properties should be made required.

In any case where `default:` is used, the property documentation should explain why the value was selected and any conditions that would make it necessary to provide a different value. (This is mandatory for built-in bindings.)

See [Example property definitions](#) for examples. Putting `default:` on any property type besides those used in the examples will raise an error.

**Enum values** The `enum:` line is followed by a list of values the property may contain. If a property value in DTS is not in the `enum:` list in the binding, an error is raised. See [Example property definitions](#) for examples.

**Const** This specifies a constant value the property must take. It is mainly useful for constraining the values of common properties for a particular piece of hardware.

**Child-binding** `child-binding` can be used when a node has children that all share the same properties. Each child gets the contents of `child-binding` as its binding, though an explicit `compatible = ...` on the child node takes precedence, if a binding is found for it.

Consider a binding for a PWM LED node like this one, where the child nodes are required to have a `pwms` property:

```
pwmleds {
    compatible = "pwm-leds";

    red_pwm_led {
        pwms = <&pwm3 4 15625000>;
    };
    green_pwm_led {
        pwms = <&pwm3 0 15625000>;
    };
    /* ... */
};
```

The binding would look like this:

```
compatible: "pwm-leds"

child-binding:
    description: LED that uses PWM

properties:
    pwms:
        type: phandle-array
        required: true
```

`child-binding` also works recursively. For example, this binding:

```
compatible: foo

child-binding:
    child-binding:
        properties:
            my-property:
```

(continues on next page)

(continued from previous page)

```
type: int
required: true
```

will apply to the `grandchild` node in this DTS:

```
parent {
    compatible = "foo";
    child {
        grandchild {
            my-property = <123>;
        };
    };
};
```

**Bus** If the node is a bus controller, use `bus:` in the binding to say what type of bus. For example, a binding for a SPI peripheral on an SoC would look like this:

```
compatible: "manufacturer,spi-peripheral"
bus: spi
# ...
```

The presence of this key in the binding informs the build system that the children of any node matching this binding appear on this type of bus.

This in turn influences the way `on-bus:` is used to match bindings for the child nodes.

**On-bus** If the node appears as a device on a bus, use `on-bus:` in the binding to say what type of bus.

For example, a binding for an external SPI memory chip should include this line:

```
on-bus: spi
```

And a binding for an I2C based temperature sensor should include this line:

```
on-bus: i2c
```

When looking for a binding for a node, the build system checks if the binding for the parent node contains `bus: <bus type>`. If it does, then only bindings with a matching `on-bus: <bus type>` and bindings without an explicit `on-bus` are considered. Bindings with an explicit `on-bus: <bus type>` are searched for first, before bindings without an explicit `on-bus`. The search repeats for each item in the node's `compatible` property, in order.

This feature allows the same device to have different bindings depending on what bus it appears on. For example, consider a sensor device with `compatible manufacturer,sensor` which can be used via either I2C or SPI.

The sensor node may therefore appear in the devicetree as a child node of either an SPI or an I2C controller, like this:

```
spi-bus@0 {
    /* ... some compatible with 'bus: spi', etc. ... */

    sensor@0 {
        compatible = "manufacturer,sensor";
        reg = <0>;
        /* ... */
    };
};
```

(continues on next page)

(continued from previous page)

```
};

i2c-bus@0 {
    /* ... some compatible with 'bus: i2c', etc. ... */

    sensor@79 {
        compatible = "manufacturer,sensor";
        reg = <79>;
        /* ... */
    };
};
```

You can write two separate binding files which match these individual sensor nodes, even though they have the same compatible:

```
# manufacturer,sensor-spi.yaml, which matches sensor@0 on the SPI bus:
compatible: "manufacturer,sensor"
on-bus: spi

# manufacturer,sensor-i2c.yaml, which matches sensor@79 on the I2C bus:
compatible: "manufacturer,sensor"
properties:
    uses-clock-stretching:
        type: boolean
        required: false
on-bus: i2c
```

Only `sensor@79` can have a `use-clock-stretching` property. The bus-sensitive logic ignores `manufacturer,sensor-i2c.yaml` when searching for a binding for `sensor@0`.

**Specifier cell names (\*-cells)** Specifier cells are usually used with `phandle-array` type properties briefly introduced above.

To understand the purpose of `*-cells`, assume that some node has the following `pwm`s property with type `phandle-array`:

```
my-device {
    pwms = <&pwm0 1 2>, <&pwm3 4>;
};
```

The tooling strips the final `s` from the property name of such properties, resulting in `pwm`. Then the value of the `#pwm-cells` property is looked up in each of the PWM controller nodes `pwm0` and `pwm3`, like so:

```
pwm0: pwm@0 {
    compatible = "foo,pwm";
    #pwm-cells = <2>;
};

pwm3: pwm@3 {
    compatible = "bar,pwm";
    #pwm-cells = <1>;
};
```

The `&pwm0 1 2` part of the property value has two cells, 1 and 2, which matches `#pwm-cells = <2>;`, so these cells are considered the *specifier* associated with `pwm0` in the phandle array.

Similarly, the cell 4 is the specifier associated with `pwm3`.

The number of PWM cells in the specifiers in `pwms` must match the `#pwm-cells` values, as shown above. If there is a mismatch, an error is raised. For example, this node would result in an error:

```
my-bad-device {
    /* wrong: 2 cells given in the specifier, but #pwm-cells is 1 in pwm3. */
    pwms = <&pwm3 5 6>;
};
```

The binding for each PWM controller must also have a `*-cells` key, in this case `pwm-cells`, giving names to the cells in each specifier:

```
# foo,pwm.yaml
compatible: "foo,pwm"
...
pwm-cells:
- channel
- period

# bar,pwm.yaml
compatible: "bar,pwm"
...
pwm-cells:
- period
```

A `*-names` (e.g. `pwm-names`) property can appear on the node as well, giving a name to each entry.

This allows the cells in the specifiers to be accessed by name, e.g. using APIs like `DT_PWMS_CHANNEL_BY_NAME`.

Because other property names are derived from the name of the property by removing the final `s`, the property name must end in `s`. An error is raised if it doesn't.

`*-gpios` properties are special-cased so that e.g. `foo-gpios` resolves to `#gpio-cells` rather than `#foo-gpio-cells`.

If the specifier is empty (e.g. `#clock-cells = <0>`), then `*-cells` can either be omitted (recommended) or set to an empty array. Note that an empty array is specified as e.g. `clock-cells: []` in YAML.

All `phandle-array` type properties support mapping through `*-map` properties, e.g. `gpio-map`, as defined by the Devicetree specification.

**Include** Bindings can include other files, which can be used to share common property definitions between bindings. Use the `include:` key for this. Its value is either a string or a list.

In the simplest case, you can include another file by giving its name as a string, like this:

```
include: foo.yaml
```

If any file named `foo.yaml` is found (see [Where bindings are located](#) for the search process), it will be included into this binding.

Included files are merged into bindings with a simple recursive dictionary merge. The build system will check that the resulting merged binding is well-formed.

It is an error if a key appears with a different value in a binding and in a file it includes, with one exception: a binding can have `required: true` for a [property definition](#) for which the included file has `required: false`. The `required: true` takes precedence, allowing bindings to strengthen requirements from included files.

Note that weakening requirements by having `required: false` where the included file has `required: true` is an error. This is meant to keep the organization clean.

The file `base.yaml` contains definitions for many common properties. When writing a new binding, it is a good idea to check if `base.yaml` already defines some of the needed properties, and include it if it does.

Note that you can make a property defined in `base.yaml` obligatory like this, taking `reg` as an example:

```
reg:
  required: true
```

This relies on the dictionary merge to fill in the other keys for `reg`, like `type`.

To include multiple files, you can use a list of strings:

```
include:
- foo.yaml
- bar.yaml
```

This includes the files `foo.yaml` and `bar.yaml`. (You can write this list in a single line of YAML as `include: [foo.yaml, bar.yaml]`.)

When including multiple files, any overlapping `required` keys on properties in the included files are ORed together. This makes sure that a `required: true` is always respected.

In some cases, you may want to include some property definitions from a file, but not all of them. In this case, `include:` should be a list, and you can filter out just the definitions you want by putting a mapping in the list, like this:

```
include:
- name: foo.yaml
  property-allowlist:
    - i-want-this-one
    - and-this-one
- name: bar.yaml
  property-blocklist:
    - do-not-include-this-one
    - or-this-one
```

Each map element must have a `name` key which is the filename to include, and may have `property-allowlist` and `property-blocklist` keys that filter which properties are included.

You cannot have a single map element with both `property-allowlist` and `property-blocklist` keys. A map element with neither `property-allowlist` nor `property-blocklist` is valid; no additional filtering is done.

You can freely intermix strings and mappings in a single `include:` list:

```
include:
- foo.yaml
- name: bar.yaml
  property-blocklist:
    - do-not-include-this-one
    - or-this-one
```

Finally, you can filter from a child binding like this:

```
include:
- name: bar.yaml
  child-binding:
    property-allowlist:
      - child-prop-to-allow
```

## Inferred bindings

Zephyr's devicetree scripts can “infer” a binding for the special `/zephyr,user` node based on the values observed in its properties.

This node matches a binding which is dynamically created by the build system based on the values of its properties in the final devicetree. It does not have a `compatible` property.

This node is meant for sample code and applications. The devicetree API provides it as a convenient container when only a few simple properties are needed, such as storing a hardware-dependent value, phandle(s), or GPIO pin.

For example, with this DTS fragment:

```
#include <dt-bindings/gpio/gpio.h>

/ {
    zephyr,user {
        boolean;
        bytes = [81 82 83];
        number = <23>;
        numbers = <1>, <2>, <3>;
        string = "text";
        strings = "a", "b", "c";

        handle = <&gpio0>;
        handles = <&gpio0>, <&gpio1>;
        signal-gpios = <&gpio0 1 GPIO_ACTIVE_HIGH>;
    };
};
```

You can get the simple values like this:

```
#define ZEPHYR_USER_NODE DT_PATH(zephyr_user)

DT_PROP(ZEPHYR_USER_NODE, boolean) // 1
DT_PROP(ZEPHYR_USER_NODE, bytes)   // {0x81, 0x82, 0x83}
DT_PROP(ZEPHYR_USER_NODE, number)  // 23
DT_PROP(ZEPHYR_USER_NODE, numbers) // {1, 2, 3}
DT_PROP(ZEPHYR_USER_NODE, string)  // "text"
DT_PROP(ZEPHYR_USER_NODE, strings) // {"a", "b", "c"}
```

You can convert the phandles in the `handle` and `handles` properties to device pointers like this:

```
/*
 * Same thing as:
 *
 * ... my_dev = DEVICE_DT_GET(DT_NODELABEL(gpio0));
 */
const struct device *my_device =
    DEVICE_DT_GET(DT_PROP(ZEPHYR_USER_NODE, handle));

#define PHANDLE_TO_DEVICE(node_id, prop, idx) \
    DEVICE_DT_GET(DT_PHANDLE_BY_IDX(node_id, prop, idx)),

/*
 * Same thing as:
 *
 * ... *my_devices[] = {
 *     DEVICE_DT_GET(DT_NODELABEL(gpio0)),
 */
```

(continues on next page)

(continued from previous page)

```

*      DEVICE_DT_GET(DT_NODELABEL(gpio1)),
* };
*/
const struct device *my_devices[] = {
    DT_FOREACH_PROP_ELEM(ZEPHYR_USER_NODE, handles, PHANDLE_TO_DEVICE)
};

```

And you can convert the pin defined in `signal-gpios` to a struct `gpio_dt_spec`, then use it like this:

```

#include <drivers/gpio.h>

#define ZEPHYR_USER_NODE DT_PATH(zephyr_user)

const struct gpio_dt_spec signal =
    GPIO_DT_SPEC_GET(ZEPHYR_USER_NODE, signal_gpios);

/* Configure the pin */
gpio_pin_configure_dt(&signal, GPIO_OUTPUT_INACTIVE);

/* Set the pin to its active level */
gpio_pin_set(signal.port, signal.pin, 1);

```

(See [gpio\\_dt\\_spec](#), [GPIO\\_DT\\_SPEC\\_GET](#), and [gpio\\_pin\\_configure\\_dt\(\)](#) for details on these APIs.)

### 8.11.4 Devicetree access from C/C++

This guide describes Zephyr's `<devicetree.h>` API for reading the devicetree from C source files. It assumes you're familiar with the concepts in [Introduction to devicetree](#) and [Devicetree bindings](#). See [Devicetree](#) for reference material.

#### A note for Linux developers

Linux developers familiar with devicetree should be warned that the API described here differs significantly from how devicetree is used on Linux.

Instead of generating a C header with all the devicetree data which is then abstracted behind a macro API, the Linux kernel would instead read the devicetree data structure in its binary form. The binary representation is parsed at runtime, for example to load and initialize device drivers.

Zephyr does not work this way because the size of the devicetree binary and associated handling code would be too large to fit comfortably on the relatively constrained devices Zephyr supports.

#### Node identifiers

To get information about a particular devicetree node, you need a *node identifier* for it. This is just a C macro that refers to the node.

These are the main ways to get a node identifier:

**By path** Use [DT\\_PATH\(\)](#) along with the node's full path in the devicetree, starting from the root node. This is mostly useful if you happen to know the exact node you're looking for.

**By node label** Use [DT\\_NODELABEL\(\)](#) to get a node identifier from a *node label*. Node labels are often provided by SoC `.dtsi` to give nodes names that match the SoC datasheet, like `i2c1`, `spi2`, etc.

**By alias** Use `DT_ALIAS()` to get a node identifier for a property of the special `/aliases` node. This is sometimes done by applications (like `blinky`, which uses the `led0` alias) that need to refer to *some* device of a particular type (“the board’s user LED”) but don’t care which one is used.

**By instance number** This is done primarily by device drivers, as instance numbers are a way to refer to individual nodes based on a matching compatible. Get these with `DT_INST()`, but be careful doing so. See below.

**By chosen node** Use `DT_CHOSEN()` to get a node identifier for `/chosen` node properties.

**By parent/child** Use `DT_PARENT()` and `DT_CHILD()` to get a node identifier for a parent or child node, starting from a node identifier you already have.

Two node identifiers which refer to the same node are identical and can be used interchangeably.

Here’s a DTS fragment for some imaginary hardware we’ll return to throughout this file for examples:

```
/dts-v1/;

/ {
    aliases {
        sensor-controller = &i2c1;
    };

    soc {
        i2c1: i2c@40002000 {
            compatible = "vnd,soc-i2c";
            label = "I2C_1";
            reg = <0x40002000 0x1000>;
            status = "okay";
            clock-frequency = < 100000 >;
        };
    };
};
```

Here are a few ways to get node identifiers for the `i2c@40002000` node:

- `DT_PATH(soc, i2c_40002000)`
- `DT_NODELABEL(i2c1)`
- `DT_ALIAS(sensor_controller)`
- `DT_INST(x, vnd_soc_i2c)` for some unknown number `x`. See the `DT_INST()` documentation for details.

---

**Important:** Non-alphanumeric characters like dash (-) and the at sign (@) in devicetree names are converted to underscores (\_). The names in a DTS are also converted to lowercase.

---

### Node identifiers are not values

There is no way to store one in a variable. You cannot write:

```
/* These will give you compiler errors: */

void *i2c_0 = DT_INST(0, vnd_soc_i2c);
unsigned int i2c_1 = DT_INST(1, vnd_soc_i2c);
long my_i2c = DT_NODELABEL(i2c1);
```

If you want something short to save typing, use C macros:

```

/* Use something like this instead: */

#define MY_I2C DT_NODELABEL(i2c1)

#define INST(i) DT_INST(i, vnd_soc_i2c)
#define I2C_0 INST(0)
#define I2C_1 INST(1)

```

## Property access

The right API to use to read property values depends on the node and property.

- [Checking properties and values](#)
- [Simple properties](#)
- [reg properties](#)
- [interrupts properties](#)
- [phandle properties](#)

**Checking properties and values** You can use `DT_NODE_HAS_PROP()` to check if a node has a property. For the [example devicetree](#) above:

```

DT_NODE_HAS_PROP(DT_NODELABEL(i2c1), clock_frequency) /* expands to 1 */
DT_NODE_HAS_PROP(DT_NODELABEL(i2c1), not_a_property)  /* expands to 0 */

```

**Simple properties** Use `DT_PROP(node_id, property)` to read basic integer, boolean, string, numeric array, and string array properties.

For example, to read the clock-frequency property's value in the [above example](#):

```

DT_PROP(DT_PATH(soc, i2c_40002000), clock_frequency) /* This is 100000, */
DT_PROP(DT_NODELABEL(i2c1), clock_frequency)         /* and so is this, */
DT_PROP(DT_ALIAS(sensor_controller), clock_frequency) /* and this. */

```

---

**Important:** The DTS property clock-frequency is spelled `clock_frequency` in C. That is, properties also need special characters converted to underscores. Their names are also forced to lowercase.

---

Properties with string and boolean types work the exact same way. The `DT_PROP()` macro expands to a string literal in the case of strings, and the number 0 or 1 in the case of booleans. For example:

```

#define I2C1 DT_NODELABEL(i2c1)

DT_PROP(I2C1, status) /* expands to the string literal "okay" */

```

---

**Note:** Don't use `DT_NODE_HAS_PROP()` for boolean properties. Use `DT_PROP()` instead as shown above. It will expand to either 0 or 1 depending on if the property is present or absent.

---

Properties with type array, uint8-array, and string-array work similarly, except `DT_PROP()` expands to an array initializer in these cases. Here is an example devicetree fragment:

```
foo: foo@1234 {
    a = <1000 2000 3000>; /* array */
    b = [aa bb cc dd];    /* uint8-array */
    c = "bar", "baz";     /* string-array */
};
```

Its properties can be accessed like this:

```
#define FOO_DT_NODELABEL(foo)

int a[] = DT_PROP(FOO, a);          /* {1000, 2000, 3000} */
unsigned char b[] = DT_PROP(FOO, b); /* {0xaa, 0xbb, 0xcc, 0xdd} */
char* c[] = DT_PROP(FOO, c);        /* {"foo", "bar"} */
```

You can use `DT_PROP_LEN()` to get logical array lengths in number of elements.

```
size_t a_len = DT_PROP_LEN(FOO, a); /* 3 */
size_t b_len = DT_PROP_LEN(FOO, b); /* 4 */
size_t c_len = DT_PROP_LEN(FOO, c); /* 2 */
```

`DT_PROP_LEN()` cannot be used with the special reg or interrupts properties. These have alternative macros which are described next.

**reg properties** See [Important properties](#) for an introduction to reg.

Given a node identifier `node_id`, `DT_NUM_REGS(node_id)` is the total number of register blocks in the node's reg property.

You **cannot** read register block addresses and lengths with `DT_PROP(node, reg)`. Instead, if a node only has one register block, use `DT_REG_ADDR()` or `DT_REG_SIZE()`:

- `DT_REG_ADDR(node_id)`: the given node's register block address
- `DT_REG_SIZE(node_id)`: its size

Use `DT_REG_ADDR_BY_IDX()` or `DT_REG_SIZE_BY_IDX()` instead if the node has multiple register blocks:

- `DT_REG_ADDR_BY_IDX(node_id, idx)`: address of register block at index `idx`
- `DT_REG_SIZE_BY_IDX(node_id, idx)`: size of block at index `idx`

The `idx` argument to these must be an integer literal or a macro that expands to one without requiring any arithmetic. In particular, `idx` cannot be a variable. This won't work:

```
/* This will cause a compiler error. */

for (size_t i = 0; i < DT_NUM_REGS(node_id); i++) {
    size_t addr = DT_REG_ADDR_BY_IDX(node_id, i);
}
```

**interrupts properties** See [Important properties](#) for a brief introduction to interrupts.

Given a node identifier `node_id`, `DT_NUM_IRQS(node_id)` is the total number of interrupt specifiers in the node's interrupts property.

The most general purpose API macro for accessing these is `DT_IRQ_BY_IDX()`:

```
DT_IRQ_BY_IDX(node_id, idx, val)
```

Here, `idx` is the logical index into the interrupts array, i.e. it is the index of an individual interrupt specifier in the property. The `val` argument is the name of a cell within the interrupt specifier. To use this macro, check the bindings file for the node you are interested in to find the `val` names.

Most Zephyr devicetree bindings have a cell named `irq`, which is the interrupt number. You can use `DT_IRQN()` as a convenient way to get a processed view of this value.

**Warning:** Here, “processed” reflects Zephyr’s devicetree *Scripts and tools*, which change the `irq` number in *zephyr.dts* to handle hardware constraints on some SoCs and in accordance with Zephyr’s multilevel interrupt numbering.

This is currently not very well documented, and you’ll need to read the scripts’ source code and existing drivers for more details if you are writing a device driver.

**phandle properties** Property values can refer to other nodes using the `&another-node` phandle syntax introduced in *Writing property values*. Properties which contain phandles have type `phandle`, `phandles`, or `phandle-array` in their bindings. We’ll call these “phandle properties” for short.

You can convert a phandle to a node identifier using `DT_PHANDLE()`, `DT_PHANDLE_BY_IDX()`, or `DT_PHANDLE_BY_NAME()`, depending on the type of property you are working with.

One common use case for phandle properties is referring to other hardware in the tree. In this case, you usually want to convert the devicetree-level phandle to a Zephyr driver-level *struct device*. See *Get a struct device from a devicetree node* for ways to do that.

Another common use case is accessing specifier values in a phandle array. The general purpose APIs for this are `DT_PHA_BY_IDX()` and `DT_PHA()`. There are also hardware-specific short-hands like `DT_GPIO_CTLR_BY_IDX()`, `DT_GPIO_CTLR()`, `DT_GPIO_LABEL_BY_IDX()`, `DT_GPIO_LABEL()`, `DT_GPIO_PIN_BY_IDX()`, `DT_GPIO_PIN()`, `DT_GPIO_FLAGS_BY_IDX()`, and `DT_GPIO_FLAGS()`.

See `DT_PHA_HAS_CELL_AT_IDX()` and `DT_PROP_HAS_IDX()` for ways to check if a specifier value is present in a phandle property.

## Other APIs

Here are pointers to some other available APIs.

- `DT_CHOSEN()`, `DT_HAS_CHOSEN()`: for properties of the special `/chosen` node
- `DT_HAS_COMPAT_STATUS_OKAY()`, `DT_NODE_HAS_COMPAT()`: global- and node-specific tests related to the compatible property
- `DT_BUS()`: get a node’s bus controller, if there is one
- `DT_ENUM_IDX()`: for properties whose values are among a fixed list of choices
- *Fixed flash partitions*: APIs for managing fixed flash partitions. Also see *Flash map*, which wraps this in a more user-friendly API.

## Device driver conveniences

Special purpose macros are available for writing device drivers, which usually rely on *instance identifiers*.

To use these, you must define `DT_DRV_COMPAT` to the `compat` value your driver implements support for. This `compat` value is what you would pass to `DT_INST()`.

If you do that, you can access the properties of individual instances of your compatible with less typing, like this:

```
#include <devicetree.h>

#define DT_DRV_COMPAT my_driver_compat
```

(continues on next page)

(continued from previous page)

```

/* This is same thing as DT_INST(0, my_driver_compat): */
DT_DRV_INST(0)

/*
 * This is the same thing as
 * DT_PROP(DT_INST(0, my_driver_compat), clock_frequency)
 */
DT_INST_PROP(0, clock_frequency)

```

See [Instance-based APIs](#) for a generic API reference.

## Hardware specific APIs

Convenience macros built on top of the above APIs are also defined to help readability for hardware specific code. See [Hardware specific APIs](#) for details.

## Generated macros

While the `devicetree.h` API is not generated, it does rely on a generated C header which is put into every application build directory: [devicetree\\_unfixed.h](#). This file contains macros with devicetree data.

These macros have tricky naming conventions which the [Devicetree API](#) abstracts away. They should be considered an implementation detail, but it's useful to understand them since they will frequently be seen in compiler error messages.

This section contains an Augmented Backus-Naur Form grammar for these generated macros, with examples and more details in comments. See RFC 7405 (which extends RFC 5234) for a syntax specification.

```

; An RFC 7405 ABNF grammar for devicetree macros.
;
; This does not cover macros pulled out of DT via Kconfig,
; like CONFIG_SRAM_BASE_ADDRESS, etc. It only describes the
; ones that start with DT_ and are directly generated, not
; defined in a dts_fixup.h file.

; -----
; dt-macro: the top level nonterminal for a devicetree macro
;
; A dt-macro starts with uppercase "DT_", and is one of:
;
; - a <node-macro>, generated for a particular node
; - some <other-macro>, a catch-all for other types of macros
dt-macro = node-macro / other-macro

; -----
; node-macro: a macro related to a node

; A macro about a property value
node-macro = property-macro
; A macro about the pinctrl properties in a node.
node-macro =/ pinctrl-macro
; EXISTS macro: node exists in the devicetree
node-macro =/ %s"DT_N" path-id %s"_EXISTS"
; Bus macros: the plain BUS is a way to access a node's bus controller.
; The additional dt-name suffix is added to match that node's bus type;
; the dt-name in this case is something like "spi" or "i2c".

```

(continues on next page)

(continued from previous page)

```

node-macro =/ %s"DT_N" path-id %s"_BUS" ["_" dt-name]
; The reg property is special and has its own macros.
node-macro =/ %s"DT_N" path-id %s"_REG_NUM"
node-macro =/ %s"DT_N" path-id %s"_REG_IDX_" DIGIT "_EXISTS"
node-macro =/ %s"DT_N" path-id %s"_REG_IDX_" DIGIT
               %s"_VAL_" ( %s"ADDRESS" / %s"SIZE")
node-macro =/ %s"DT_N" path-id %s"_REG_NAME_" dt-name
               %s"_VAL_" ( %s"ADDRESS" / %s"SIZE")
; The interrupts property is also special.
node-macro =/ %s"DT_N" path-id %s"_IRQ_NUM"
node-macro =/ %s"DT_N" path-id %s"_IRQ_IDX_" DIGIT "_EXISTS"
node-macro =/ %s"DT_N" path-id %s"_IRQ_IDX_" DIGIT
               %s"_VAL_" dt-name [ %s"_EXISTS" ]
node-macro =/ %s"DT_N" path-id %s"_IRQ_NAME_" dt-name
               %s"_VAL_" dt-name [ %s"_EXISTS" ]
; Subnodes of the fixed-partitions compatible get macros which contain
; a unique ordinal value for each partition
node-macro =/ %s"DT_N" path-id %s"_PARTITION_ID" DIGIT
; Macros are generated for each of a node's compatibles;
; dt-name in this case is something like "vnd_device".
node-macro =/ %s"DT_N" path-id %s"_COMPAT_MATCHES_" dt-name
; Every non-root node gets one of these macros, which expands to the node
; identifier for that node's parent in the devicetree.
node-macro =/ %s"DT_N" path-id %s"_PARENT"
; These are used internally by DT_FOREACH_CHILD, which iterates over
; each child node.
node-macro =/ %s"DT_N" path-id %s"_FOREACH_CHILD"
node-macro =/ %s"DT_N" path-id %s"_FOREACH_CHILD_VARS"
; These are used internally by DT_FOREACH_CHILD_STATUS_OKAY, which iterates
; over each child node with status "okay".
node-macro =/ %s"DT_N" path-id %s"_FOREACH_CHILD_STATUS_OKAY"
node-macro =/ %s"DT_N" path-id %s"_FOREACH_CHILD_STATUS_OKAY_VARS"
; The node's status macro; dt-name in this case is something like "okay"
; or "disabled".
node-macro =/ %s"DT_N" path-id %s"_STATUS_" dt-name
; The node's dependency ordinal. This is a non-negative integer
; value that is used to represent dependency information.
node-macro =/ %s"DT_N" path-id %s"_ORD"
; The node's path, as a string literal
node-macro =/ %s"DT_N" path-id %s"_PATH"
; The node's name@unit-addr, as a string literal
node-macro =/ %s"DT_N" path-id %s"_FULL_NAME"
; The dependency ordinals of a node's requirements (direct dependencies).
node-macro =/ %s"DT_N" path-id %s"_REQUIRES_ORDS"
; The dependency ordinals of a node supports (reverse direct dependencies).
node-macro =/ %s"DT_N" path-id %s"_SUPPORTS_ORDS"

; -----
; pinctrl-macro: a macro related to the pinctrl properties in a node
;
; These are a bit of a special case because they kind of form an array,
; but the array indexes correspond to pinctrl-DIGIT properties in a node.
;
; So they're related to a node, but not just one property within the node.
;
; The following examples assume something like this:

```

(continues on next page)

(continued from previous page)

```

;
;   foo {
;       pinctrl-0 = <&bar>;
;       pinctrl-1 = <&baz>;
;       pinctrl-names = "default", "sleep";
;   };

; Total number of pinctrl-DIGIT properties in the node. May be zero.
;
;   #define DT_N_<node path>_PINCTRL_NUM 2
pinctrl-macro = %s"DT_N" path-id %s"_PINCTRL_NUM"
; A given pinctrl-DIGIT property exists.
;
;   #define DT_N_<node path>_PINCTRL_IDX_0_EXISTS 1
;   #define DT_N_<node path>_PINCTRL_IDX_1_EXISTS 1
pinctrl-macro =/ %s"DT_N" path-id %s"_PINCTRL_IDX_" DIGIT %s"_EXISTS"
; A given pinctrl property name exists.
;
;   #define DT_N_<node path>_PINCTRL_NAME_default_EXISTS 1
;   #define DT_N_<node path>_PINCTRL_NAME_sleep_EXISTS 1
pinctrl-macro =/ %s"DT_N" path-id %s"_PINCTRL_NAME_" dt-name %s"_EXISTS"
; The corresponding index number of a named pinctrl property.
;
;   #define DT_N_<node path>_PINCTRL_NAME_default_IDX 0
;   #define DT_N_<node path>_PINCTRL_NAME_sleep_IDX 1
pinctrl-macro =/ %s"DT_N" path-id %s"_PINCTRL_NAME_" dt-name %s"_IDX"
; The node identifier for the phandle in a named pinctrl property.
;
;   #define DT_N_<node path>_PINCTRL_NAME_default_IDX_0_PH <node id for 'bar'>
;
; There's no need for a separate macro for access by index: that's
; covered by property-macro. We only need this because the map from
; names to properties is implicit in the structure of the DT.
pinctrl-macro =/ %s"DT_N" path-id %s"_PINCTRL_NAME_" dt-name %s"_IDX_" DIGIT %s"_PH"

; -----
; property-macro: a macro related to a node property
;
; These combine a node identifier with a "lowercase-and-underscores form"
; property name. The value expands to something related to the property's
; value.
;
; The optional prop-suf suffix is when there's some specialized
; subvalue that deserves its own macro, like the macros for an array
; property's individual elements
;
; The "plain vanilla" macro for a property's value, with no prop-suf,
; looks like this:
;
;   DT_N_<node path>_P_<property name>
;
; Components:
;
; - path-id: node's devicetree path converted to a C token
; - prop-id: node's property name converted to a C token
; - prop-suf: an optional property-specific suffix

```

(continues on next page)

(continued from previous page)

```

property-macro = %s"DT_N" path-id %s"_P_" prop-id [prop-suf]

; -----
; path-id: a node's path-based macro identifier
;
; This in "lowercase-and-underscores" form. I.e. it is
; the node's devicetree path converted to a C token by changing:
;
; - each slash (/) to _S_
; - all letters to lowercase
; - non-alphanumerics characters to underscores
;
; For example, the leaf node "bar-BAZ" in this devicetree:
;
; / {
;     foo@123 {
;         bar-BAZ {};
;     };
; };
;
; has path-id "_S_foo_123_S_bar_baz".
path-id = 1*( %s"_S_" dt-name )

; -----
; prop-id: a property identifier
;
; A property name converted to a C token by changing:
;
; - all letters to lowercase
; - non-alphanumeric characters to underscores
;
; Example node:
;
; chosen {
;     zephyr,console = &uart1;
;     WHY,AM_I_SHOUTING = "unclear";
; };
;
; The 'zephyr,console' property has prop-id 'zephyr_console'.
; 'WHY,AM_I_SHOUTING' has prop-id 'why_am_i_shouting'.
prop-id = dt-name

; -----
; prop-suf: a property-specific macro suffix
;
; Extra macros are generated for properties:
;
; - that are special to the specification ("reg", "interrupts", etc.)
; - with array types (uint8-array, phandle-array, etc.)
; - with "enum:" in their bindings
; - that have zephyr device API specific macros for phandle-arrays
; - related to phandle specifier names ("foo-names")
;
; Here are some examples:
;
; - _EXISTS: property, index or name existence flag

```

(continues on next page)

(continued from previous page)

```

; - _SIZE: logical property length
; - _IDX<i>: values of individual array elements
; - _IDX<DIGIT>_VAL<dt-name>: values of individual specifier
;   cells within a phandle array
; - _ADDR<i>: for reg properties, the i-th register block address
; - _LEN<i>: for reg properties, the i-th register block length
;
; The different cases are not exhaustively documented here to avoid
; this file going stale. Please see devicetree.h if you need to know
; the details.
prop-suf = 1*( "-" gen-name ["-" dt-name] )

; -----
; other-macro: grab bag for everything that isn't a node-macro.

; See examples below.
other-macro = %s"DT_N-" alternate-id
; Total count of enabled instances of a compatible.
other-macro =/ %s"DT_N_INST-" dt-name %s"_NUM_OKAY"
; These are used internally by DT_FOREACH_STATUS_OKAY,
; which iterates over each enabled node of a compatible.
other-macro =/ %s"DT_FOREACH_OKAY-" dt-name
other-macro =/ %s"DT_FOREACH_OKAY_VARS-" dt-name
; These are used internally by DT_INST_FOREACH_STATUS_OKAY,
; which iterates over each enabled instance of a compatible.
other-macro =/ %s"DT_FOREACH_OKAY_INST-" dt-name
other-macro =/ %s"DT_FOREACH_OKAY_INST_VARS-" dt-name
; E.g.: #define DT_CHOSEN_zephyr_flash
other-macro =/ %s"DT_CHOSEN-" dt-name
; Declares that a compatible has at least one node on a bus.
; Example:
;
; #define DT_COMPAT_vnd_dev_BUS_spi 1
other-macro =/ %s"DT_COMPAT-" dt-name %s"_BUS-" dt-name
; Declares that a compatible has at least one status "okay" node.
; Example:
;
; #define DT_COMPAT_HAS_OKAY_vnd_dev 1
other-macro =/ %s"DT_COMPAT_HAS_OKAY-" dt-name
; Currently used to allow mapping a lowercase-and-underscores "label"
; property to a fixed-partitions node. See the flash map API docs
; for an example.
other-macro =/ %s"DT_COMPAT-" dt-name %s"_LABEL-" dt-name

; -----
; alternate-id: another way to specify a node besides a path-id
;
; Example devicetree:
;
; / {
;     aliases {
;         dev = &dev_1;
;     };
;
;     soc {
;         dev_1: device@123 {

```

(continues on next page)

(continued from previous page)

```

;             compatible = "vnd,device";
;             };
;         };
;     };
;
; Node device@123 has these alternate-id values:
;
; - ALIAS_dev
; - NODELABEL_dev_1
; - INST_0_vnd_device
;
; The full alternate-id macros are:
;
; #define DT_N_INST_0_vnd_device    DT_N_S_soc_S_device_123
; #define DT_N_ALIAS_dev           DT_N_S_soc_S_device_123
; #define DT_N_NODELABEL_dev_1     DT_N_S_soc_S_device_123
;
; These mainly exist to allow pasting an alternate-id macro onto a
; "_P_<prop-id>" to access node properties given a node's alias, etc.
;
; Notice that "inst"-type IDs have a leading instance identifier,
; which is generated by the devicetree scripts. The other types of
; alternate-id begin immediately with names taken from the devicetree.
alternate-id = ( %s"ALIAS" / %s"NODELABEL" ) dt-name
alternate-id =/ %s"INST_" 1*DIGIT "_" dt-name

; -----
; miscellaneous helper definitions

; A dt-name is one or more:
; - lowercase ASCII letters (a-z)
; - numbers (0-9)
; - underscores ("_")
;
; They are the result of converting names or combinations of names
; from devicetree to a valid component of a C identifier by
; lowercasing letters (in practice, this is a no-op) and converting
; non-alphanumeric characters to underscores.
;
; You'll see these referred to as "lowercase-and-underscores" forms of
; various devicetree identifiers throughout the documentation.
dt-name = 1*( lower / DIGIT / "_" )

; gen-name is used as a stand-in for a component of a generated macro
; name which does not come from devicetree (dt-name covers that case).
;
; - uppercase ASCII letters (a-z)

### 8.11.5 Devicetree HOWTOs

This page has step-by-step advice for getting things done with devicetree.

---

**Tip:** See [Troubleshooting devicetree](#) for troubleshooting advice.

---

#### Get your devicetree and generated header

A board's devicetree ([BOARD.dts](#)) pulls in common node definitions via `#include` preprocessor directives. This at least includes the SoC's `.dtsi`. One way to figure out the devicetree's contents is by opening these files, e.g. by looking in `dtb/<ARCH>/<vendor>/<soc>.dtsi`, but this can be time consuming.

If you just want to see the “final” devicetree for your board, build an application and open the `zephyr.dts` file in the build directory.

---

**Tip:** You can build `hello_world` to see the “base” devicetree for your board without any additional changes from [overlay files](#).

---

For example, using the `qemu_cortex_m3` board to build `hello_world`:

```
# --cmake-only here just forces CMake to run, skipping the
# build process to save time.
west build -b qemu_cortex_m3 -s samples/hello_world --cmake-only
```

You can change `qemu_cortex_m3` to match your board.

CMake prints the input and output file locations like this:

```
-- Found BOARD.dts: .../zephyr/boards/arm/qemu_cortex_m3/qemu_cortex_m3.dts
-- Generated zephyr.dts: .../zephyr/build/zephyr/zephyr.dts
-- Generated devicetree_unfixed.h: .../zephyr/build/zephyr/include/generated/
↳ devicetree_unfixed.h
```

The `zephyr.dts` file is the final devicetree in DTS format.

The `devicetree_unfixed.h` file is the corresponding generated header.

See [Input and output files](#) for details about these files.

#### Get a struct device from a devicetree node

When writing Zephyr applications, you'll often want to get a driver-level [struct device](#) corresponding to a devicetree node.

For example, with this devicetree fragment, you might want the struct device for `serial@40002000`:

```
/ {
    soc {
        serial0: serial@40002000 {
```

(continues on next page)

(continued from previous page)

```

        status = "okay";
        current-speed = <115200>;
        /* ... */
    };
};

aliases {
    my-serial = &serial0;
};

chosen {
    zephyr,console = &serial0;
};
};

```

Start by making a [node identifier](#) for the device you are interested in. There are different ways to do this; pick whichever one works best for your requirements. Here are some examples:

```

/* Option 1: by node label */
#define MY_SERIAL DT_NODELABEL(serial0)

/* Option 2: by alias */
#define MY_SERIAL DT_ALIAS(my_serial)

/* Option 3: by chosen node */
#define MY_SERIAL DT_CHOSEN(zephyr_console)

/* Option 4: by path */
#define MY_SERIAL DT_PATH(soc, serial_40002000)

```

Once you have a node identifier there are two ways to proceed. The classic way is to get the struct device by combining [DT\\_LABEL\(\)](#) with [device\\_get\\_binding\(\)](#):

```
const struct device *uart_dev = device_get_binding(DT_LABEL(MY_SERIAL));
```

You can then use `uart_dev` with [UART](#) API functions like [uart\\_configure\(\)](#). Similar code will work for other device types; just make sure you use the correct API for the device.

There's no need to override the `label` property to something else: just make a node identifier and pass it to `DT_LABEL` to get the right string to pass to `device_get_binding()`.

The second way to get a device is to use [DEVICE\\_DT\\_GET\(\)](#):

```
const struct device *uart_dev = DEVICE_DT_GET(MY_SERIAL);

if (!device_is_ready(uart_dev)) {
    /* Not ready, do not use */
    return -ENODEV;
}

```

This idiom fetches the device pointer at build-time, which is useful when you want to store the device pointer as configuration data. But because the device may not be initialized, or may have failed to initialize, you must verify that the device is ready to be used before passing it to any API functions. (This check is done for you by [device\\_get\\_binding\(\)](#).)

If you're having trouble, see [Troubleshooting devicetree](#). The first thing to check is that the node has `status = "okay"`, like this:

```
#define MY_SERIAL DT_NODELABEL(my_serial)

#if DT_NODE_HAS_STATUS(MY_SERIAL, okay)
const struct device *uart_dev = device_get_binding(DT_LABEL(MY_SERIAL));
#else
#error "Node is disabled"
#endif
```

If you see the `#error` output, make sure to enable the node in your devicetree. If you don't see the `#error` but `uart_dev` is `NULL`, then there's likely either a Kconfig issue preventing the device driver from creating the device, or the device's initialization function failed.

### Find a devicetree binding

*Devicetree bindings* are YAML files which declare what you can do with the nodes they describe, so it's critical to be able to find them for the nodes you are using.

If you don't have them already, [Get your devicetree and generated header](#). To find a node's binding, open the generated header file, which starts with a list of nodes in a block comment:

```
/*
 * [...]
 * Nodes in dependency order (ordinal and path):
 * 0 /
 * 1 /aliases
 * 2 /chosen
 * 3 /flash@0
 * 4 /memory@20000000
 *   (etc.)
 * [...]
 */
```

Make note of the path to the node you want to find, like `/flash@0`. Search for the node's output in the file, which starts with something like this if the node has a matching binding:

```
/*
 * Devicetree node:
 * /flash@0
 *
 * Binding (compatible = soc-nv-flash):
 * $ZEPHYR_BASE/dts/bindings/mtd/soc-nv-flash.yaml
 * [...]
 */
```

See [Check for missing bindings](#) for troubleshooting.

### Set devicetree overlays

Devicetree overlays are explained in [Introduction to devicetree](#). The CMake variable `DTC_OVERLAY_FILE` contains a space- or semicolon-separated list of overlays. If `DTC_OVERLAY_FILE` specifies multiple files, they are included in that order by the C preprocessor.

Here are some ways to set it:

1. on the cmake build command line (`-DDTC_OVERLAY_FILE="file1.overlay;file2.overlay"`)
2. with the CMake `set()` command in the application `CMakeLists.txt`, before including zephyr's boilerplate.cmake file

3. using a DTC\_OVERLAY\_FILE environment variable (deprecated)
4. create a boards/<BOARD>\_<revision>.overlay file in the application folder for the current board revision. This requires that the board supports multiple revisions, see [Multiple board revisions](#). The boards/<BOARD>\_<revision>.overlay file will be merged with boards/<BOARD>.overlay if this file also exists.
5. create a boards/<BOARD>.overlay file in the application folder, for the current board
6. create a <BOARD>.overlay file in the application folder
7. create an app.overlay file in the application folder

Here is an example [using west build](#). However you set the value, it is saved in the CMake cache between builds.

The [build system](#) prints all the devicetree overlays it finds in the configuration phase, like this:

```
-- Found devicetree overlay: .../some/file.overlay
```

## Use devicetree overlays

See [Set devicetree overlays](#) for how to add an overlay to the build.

Overlays can override node property values in multiple ways. For example, if your BOARD.dts contains this node:

```
/ {
    soc {
        serial0: serial@40002000 {
            status = "okay";
            current-speed = <115200>;
            /* ... */
        };
    };
};
```

These are equivalent ways to override the current-speed value in an overlay:

```
/* Option 1 */
&serial0 {
    current-speed = <9600>;
};

/* Option 2 */
&{/soc/serial@40002000} {
    current-speed = <9600>;
};
```

We'll use the &serial0 style for the rest of these examples.

You can add aliases to your devicetree using overlays: an alias is just a property of the /aliases node. For example:

```
/ {
    aliases {
        my-serial = &serial0;
    };
};
```

Chosen nodes work the same way. For example:

```
/ {
    chosen {
        zephyr,console = &serial0;
    };
};
```

To delete a property (in addition to deleting properties in general, this is how to set a boolean property to false if it's true in BOARD.dts):

```
&serial0 {
    /delete-property/ some-unwanted-property;
};
```

You can add subnodes using overlays. For example, to configure a SPI or I2C child device on an existing bus node, do something like this:

```
/* SPI device example */
&spi1 {
    my_spi_device: temp-sensor@0 {
        compatible = "...";
        label = "TEMP_SENSOR_0";
        /* reg is the chip select number, if needed;
         * If present, it must match the node's unit address. */
        reg = <0>;

        /* Configure other SPI device properties as needed.
         * Find your device's DT binding for details. */
        spi-max-frequency = <4000000>;
    };
};

/* I2C device example */
&i2c2 {
    my_i2c_device: touchscreen@76 {
        compatible = "...";
        label = "TOUCHSCREEN";
        /* reg is the I2C device address.
         * It must match the node's unit address. */
        reg = <76>;

        /* Configure other I2C device properties as needed.
         * Find your device's DT binding for details. */
    };
};
```

Other bus devices can be configured similarly:

- create the device as a subnode of the parent bus
- set its properties according to its binding

Assuming you have a suitable device driver associated with the `my_spi_device` and `my_i2c_device` compatibles, you should now be able to enable the driver via Kconfig and [get the struct device](#) for your newly added bus node, then use it with that driver API.

### Write device drivers using devicetree APIs

“Devicetree-aware” [device drivers](#) should create a struct device for each status = "okay" devicetree node with a particular [compatible](#) (or related set of compatibles) supported by the driver.

**Note:** Historically, Zephyr has used Kconfig options like `:kconfig: `CONFIG_I2C_0`` and `:kconfig: `CONFIG_I2C_1`` to enable driver support for individual devices of some type. For example, if `CONFIG_I2C_1=y`, the SoC's I2C peripheral driver would create a struct device for "I2C bus controller number 1".

This style predates support for devicetree in Zephyr and its use is now discouraged. Existing device drivers may be made "devicetree-aware" in future releases.

Writing a devicetree-aware driver begins by defining a [devicetree binding](#) for the devices supported by the driver. Use existing bindings from similar drivers as a starting point. A skeletal binding to get started needs nothing more than this:

```
description: <Human-readable description of your binding>
compatible: "foo-company,bar-device"
include: base.yaml
```

See [Find a devicetree binding](#) for more advice on locating existing bindings.

After writing your binding, your driver C file can then use the devicetree API to find status = "okay" nodes with the desired compatible, and instantiate a struct device for each one. There are two options for instantiating each struct device: using instance numbers, and using node labels.

In either case:

- Each struct device's name should be set to its devicetree node's label property. This allows the driver's users to [Get a struct device from a devicetree node](#) in the usual way.
- Each device's initial configuration should use values from devicetree properties whenever practical. This allows users to configure the driver using [devicetree overlays](#).

Examples for how to do this follow. They assume you've already implemented the device-specific configuration and data structures and API functions, like this:

```
/* my_driver.c */
#include <drivers/some_api.h>

/* Define data (RAM) and configuration (ROM) structures: */
struct my_dev_data {
    /* per-device values to store in RAM */
};
struct my_dev_cfg {
    uint32_t freq; /* Just an example: initial clock frequency in Hz */
    /* other configuration to store in ROM */
};

/* Implement driver API functions (drivers/some_api.h callbacks): */
static int my_driver_api_func1(const struct device *dev, uint32_t *foo) { /* ... */ }
static int my_driver_api_func2(const struct device *dev, uint64_t bar) { /* ... */ }
static struct some_api my_api_funcs = {
    .func1 = my_driver_api_func1,
    .func2 = my_driver_api_func2,
};
```

**Option 1: create devices using instance numbers** Use this option, which uses [Instance-based APIs](#), if possible. However, they only work when devicetree nodes for your driver's compatible are all equivalent, and you do not need to be able to distinguish between them.

To use instance-based APIs, begin by defining DT\_DRV\_COMPAT to the lowercase-and-underscores version

of the compatible that the device driver supports. For example, if your driver's compatible is "vnd, my-device" in devicetree, you would define DT\_DRV\_COMPAT to vnd\_my\_device in your driver C file:

```
/*
 * Put this near the top of the file. After the includes is a good place.
 * (Note that you can therefore run "git grep DT_DRV_COMPAT drivers" in
 * the zephyr Git repository to look for example drivers using this style).
 */
#define DT_DRV_COMPAT vnd_my_device
```

---

**Important:** As shown, the DT\_DRV\_COMPAT macro should have neither quotes nor special characters. Remove quotes and convert special characters to underscores when creating DT\_DRV\_COMPAT from the compatible property.

---

Finally, define an instantiation macro, which creates each struct device using instance numbers. Do this after defining my\_api\_funcs.

```
/*
 * This instantiation macro is named "CREATE_MY_DEVICE".
 * Its "inst" argument is an arbitrary instance number.
 *
 * Put this near the end of the file, e.g. after defining "my_api_funcs".
 */
#define CREATE_MY_DEVICE(inst) \
    static struct my_dev_data my_data_##inst = { \
        /* initialize RAM values as needed, e.g.: */ \
        .freq = DT_INST_PROP(inst, clock_frequency), \
    }; \
    static const struct my_dev_cfg my_cfg_##inst = { \
        /* initialize ROM values as needed. */ \
    }; \
    DEVICE_DT_INST_DEFINE(inst, \
        my_dev_init_function, \
        NULL, \
        &my_data_##inst, \
        &my_cfg_##inst, \
        MY_DEV_INIT_LEVEL, MY_DEV_INIT_PRIORITY, \
        &my_api_funcs);
```

Notice the use of APIs like [DT\\_INST\\_PROP\(\)](#) and [DEVICE\\_DT\\_INST\\_DEFINE\(\)](#) to access devicetree node data. These APIs retrieve data from the devicetree for instance number inst of the node with compatible determined by DT\_DRV\_COMPAT.

Finally, pass the instantiation macro to [DT\\_INST\\_FOREACH\\_STATUS\\_OKAY\(\)](#):

```
/* Call the device creation macro for each instance: */
DT_INST_FOREACH_STATUS_OKAY(CREATE_MY_DEVICE)
```

DT\_INST\_FOREACH\_STATUS\_OKAY expands to code which calls CREATE\_MY\_DEVICE once for each enabled node with the compatible determined by DT\_DRV\_COMPAT. It does not append a semicolon to the end of the expansion of CREATE\_MY\_DEVICE, so the macro's expansion must end in a semicolon or function definition to support multiple devices.

**Option 2: create devices using node labels** Some device drivers cannot use instance numbers. One example is an SoC peripheral driver which relies on vendor HAL APIs specialized for individual IP blocks to implement Zephyr driver callbacks. Cases like this should use [DT\\_NODELABEL\(\)](#) to refer to individual

nodes in the devicetree representing the supported peripherals on the SoC. The devicetree.h [Generic APIs](#) can then be used to access node data.

For this to work, your [SoC's dtsi file](#) must define node labels like `mydevice0`, `mydevice1`, etc. appropriately for the IP blocks your driver supports. The resulting devicetree usually looks something like this:

```
/ {
    soc {
        mydevice0: dev@0 {
            compatible = "vnd,my-device";
        };
        mydevice1: dev@1 {
            compatible = "vnd,my-device";
        };
    };
};
```

The driver can use the `mydevice0` and `mydevice1` node labels in the devicetree to operate on specific device nodes:

```
/*
 * This is a convenience macro for creating a node identifier for
 * the relevant devices. An example use is MYDEV(0) to refer to
 * the node with label "mydevice0".
 */
#define MYDEV(idx) DT_NODELABEL(mydevice ## idx)

/*
 * Define your instantiation macro; "idx" is a number like 0 for mydevice0
 * or 1 for mydevice1. It uses MYDEV() to create the node label from the
 * index.
 */
#define CREATE_MY_DEVICE(idx) \
    static struct my_dev_data my_data_##idx = { \
        /* initialize RAM values as needed, e.g.: */ \
        .freq = DT_PROP(MYDEV(idx), clock_frequency), \
    }; \
    static const struct my_dev_cfg my_cfg_##idx = { /* ... */ }; \
    DEVICE_DT_DEFINE(MYDEV(idx), \
        my_dev_init_function, \
        NULL, \
        &my_data_##idx, \
        &my_cfg_##idx, \
        MY_DEV_INIT_LEVEL, MY_DEV_INIT_PRIORITY, \
        &my_api_funcs)
```

Notice the use of APIs like `DT_PROP()` and `DEVICE_DT_DEFINE()` to access devicetree node data.

Finally, manually detect each enabled devicetree node and use `CREATE_MY_DEVICE` to instantiate each struct device:

```
#if DT_NODE_HAS_STATUS(DT_NODELABEL(mydevice0), okay)
CREATE_MY_DEVICE(0)
#endif

#if DT_NODE_HAS_STATUS(DT_NODELABEL(mydevice1), okay)
CREATE_MY_DEVICE(1)
#endif
```

Since this style does not use `DT_INST_FOREACH_STATUS_OKAY()`, the driver author is responsible for calling `CREATE_MY_DEVICE()` for every possible node, e.g. using knowledge about the peripherals available on supported SoCs.

### Device drivers that depend on other devices

At times, one struct device depends on another struct device and requires a pointer to it. For example, a sensor device might need a pointer to its SPI bus controller device. Some advice:

- Write your devicetree binding in a way that permits use of *Hardware specific APIs* from `devicetree.h` if possible.
- In particular, for bus devices, your driver's binding should include a file like `dt/bindings/spi/spi-device.yaml` which provides common definitions for devices addressable via a specific bus. This enables use of APIs like `DT_BUS()` to obtain a node identifier for the bus node. You can then *Get a struct device from a devicetree node* for the bus in the usual way.

Search existing bindings and device drivers for examples.

### Applications that depend on board-specific devices

One way to allow application code to run unmodified on multiple boards is by supporting a devicetree alias to specify the hardware specific portions, as is done in the blinky-sample. The application can then be configured in `BOARD.dts` files or via *devicetree overlays*.

## 8.11.6 Troubleshooting devicetree

Here are some tips for fixing misbehaving devicetree related code.

See *Devicetree HOWTOs* for other “HOWTO” style information.

### Try again with a pristine build directory

---

**Important:** Try this first, before doing anything else.

---

See *Pristine Builds* for examples, or just delete the build directory completely and retry.

This is general advice which is especially applicable to debugging devicetree issues, because the outputs are created during the CMake configuration phase, and are not always regenerated when one of their inputs changes.

### Make sure `<devicetree.h>` is included

Unlike Kconfig symbols, the `devicetree.h` header must be included explicitly.

Many Zephyr header files rely on information from `devicetree`, so including some other API may transitively include `devicetree.h`, but that's not guaranteed.

### Make sure you're using the right names

Remember that:

- In C/C++, devicetree names must be lowercased and special characters must be converted to underscores. Zephyr's generated devicetree header has DTS names converted in this way into the C tokens used by the preprocessor-based `<devicetree.h>` API.

- In overlays, use devicetree node and property names the same way they would appear in any DTS file. Zephyr overlays are just DTS fragments.

For example, if you're trying to **get** the clock-frequency property of a node with path `/soc/i2c@12340000` in a C/C++ file:

```
/*
 * foo.c: lowercase-and-underscores names
 */

/* Don't do this: */
#define MY_CLOCK_FREQ DT_PROP(DT_PATH(soc, i2c@1234000), clock-frequency)
/*
 *
 * @ should be _ - should be _ */

/* Do this instead: */
#define MY_CLOCK_FREQ DT_PROP(DT_PATH(soc, i2c_1234000), clock_frequency)
/*
 *
 * */
```

And if you're trying to **set** that property in a devicetree overlay:

```
/*
 * foo.overlay: DTS names with special characters, etc.
 */

/* Don't do this; you'll get devicetree errors. */
&{/soc/i2c_12340000/} {
    clock_frequency = <115200>;
};

/* Do this instead. Overlays are just DTS fragments. */
&{/soc/i2c@12340000/} {
    clock-frequency = <115200>;
};
```

## Look at the preprocessor output

To save preprocessor output when using GCC-based toolchains, add `-save-temps=obj` to the `EXTRA_CFLAGS` CMake variable. For example, to build `hello_world` with `west` with this option set, use:

```
west build -b BOARD samples/hello_world -- -DEXTRA_CFLAGS=-save-temps=obj
```

This will create a preprocessor output file named `foo.c.i` in the build directory for each source file `foo.c`.

You can then search for the file in the build directory to see what your devicetree macros expanded to. For example, on macOS and Linux, using `find` to find `main.c.i`:

```
$ find build -name main.c.i
build/CMakeFiles/app.dir/src/main.c.i
```

It's usually easiest to run a style formatter on the results before opening them. For example, to use `clang-format` to reformat the file in place:

```
clang-format -i build/CMakeFiles/app.dir/src/main.c.i
```

You can then open the file in your favorite editor to view the final C results after preprocessing.

## Validate properties

If you're getting a compile error reading a node property, check your node identifier and property. For example, if you get a build error on a line that looks like this:

```
int baud_rate = DT_PROP(DT_NODELABEL(my_serial), current_speed);
```

Try checking the node by adding this to the file and recompiling:

```
#if !DT_NODE_EXISTS(DT_NODELABEL(my_serial))
#error "whoops"
#endif
```

If you see the “whoops” error message when you rebuild, the node identifier isn't referring to a valid node. [Get your devicetree and generated header](#) and debug from there.

Some hints for what to check next if you don't see the “whoops” error message:

- did you [Make sure you're using the right names](#)?
- does the [property exist](#)?
- does the node have a [matching binding](#)?
- does the binding define the property?

## Check for missing bindings

See [Devicetree bindings](#) for information about bindings, and [Bindings index](#) for information on bindings built into Zephyr.

If the build fails to [Find a devicetree binding](#) for a node, then either the node's compatible property is not defined, or its value has no matching binding. If the property is set, check for typos in its name. In a devicetree source file, compatible should look like "vnd,some-device" – [Make sure you're using the right names](#).

If your binding file is not under `zephyr/dts`, you may need to set `DTS_ROOT`; see [Where bindings are located](#).

## Errors with DT\_INST\_() APIs

If you're using an API like `DT_INST_PROP()`, you must define `DT_DRV_COMPAT` to the lowercase-and-underscores version of the compatible you are interested in. See [Option 1: create devices using instance numbers](#).

### 8.11.7 Devicetree versus Kconfig

Along with devicetree, Zephyr also uses the Kconfig language to configure the source code. Whether to use devicetree or Kconfig for a particular purpose can sometimes be confusing. This section should help you decide which one to use.

In short:

- Use devicetree to describe **hardware** and its **boot-time configuration**. Examples include peripherals on a board, boot-time clock frequencies, interrupt lines, etc.
- Use Kconfig to configure **software support** to build into the final image. Examples include whether to add networking support, which drivers are needed by the application, etc.

In other words, devicetree mainly deals with hardware, and Kconfig with software.

For example, consider a board containing a SoC with 2 UART, or serial port, instances.

- The fact that the board has this UART **hardware** is described with two UART nodes in the device-tree. These provide the UART type (via the `compatible` property) and certain settings such as the address range of the hardware peripheral registers in memory (via the `reg` property).
- Additionally, the UART **boot-time configuration** is also described with devicetree. This could include configuration such as the RX IRQ line's priority and the UART baud rate. These may be modifiable at runtime, but their boot-time configuration is described in devicetree.
- Whether or not to include **software support** for UART in the build is controlled via Kconfig. Applications which do not need to use the UARTs can remove the driver source code from the build using Kconfig, even though the board's devicetree still includes UART nodes.

As another example, consider a device with a 2.4GHz, multi-protocol radio supporting both the Bluetooth Low Energy and 802.15.4 wireless technologies.

- Devicetree should be used to describe the presence of the radio **hardware**, what driver or drivers it's compatible with, etc.
- **Boot-time configuration** for the radio, such as TX power in dBm, should also be specified using devicetree.
- Kconfig should determine which **software features** should be built for the radio, such as selecting a BLE or 802.15.4 protocol stack.

As another example, Kconfig options that formerly enabled a particular instance of a driver (that is itself enabled by Kconfig) have been removed. The devices are selected individually using devicetree's [status](#) keyword on the corresponding hardware instance.

There are **exceptions** to these rules:

- Because Kconfig is unable to flexibly control some instance-specific driver configuration parameters, such as the size of an internal buffer, these options may be defined in devicetree. However, to make clear that they are specific to Zephyr drivers and not hardware description or configuration these properties should be prefixed with `zephyr,`, e.g. `zephyr,random-mac-address` in the common Ethernet devicetree properties.
- Devicetree's chosen keyword, which allows the user to select a specific instance of a hardware device to be used for a particular purpose. An example of this is selecting a particular UART for use as the system's console.

## 8.12 Peripheral and Hardware Emulators

### 8.12.1 Overview

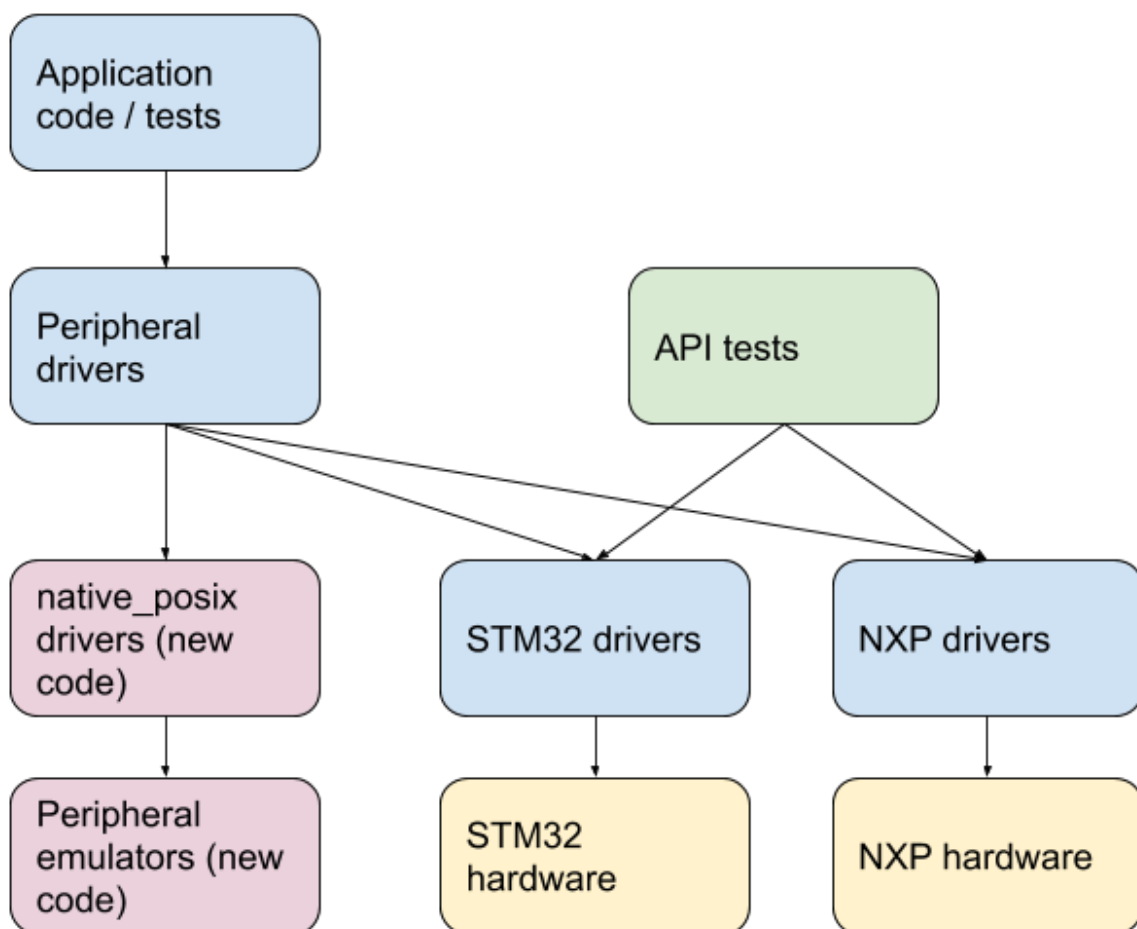

Zephyr supports a simple emulator framework to support testing of drivers without requiring real hardware.

Emulators are used to emulate hardware devices, to support testing of various subsystems. For example, it is possible to write an emulator for an I2C compass such that it appears on the I2C bus and can be used just like a real hardware device.

Emulators often implement special features for testing. For example a compass may support returning bogus data if the I2C bus speed is too high, or may return invalid measurements if calibration has not yet been completed. This allows for testing that high-level code can handle these situations correctly. Test coverage can therefore approach 100% if all failure conditions are emulated.

### 8.12.2 Concept

The diagram below shows application code / high-level tests at the top. This is the ultimate application we want to run.

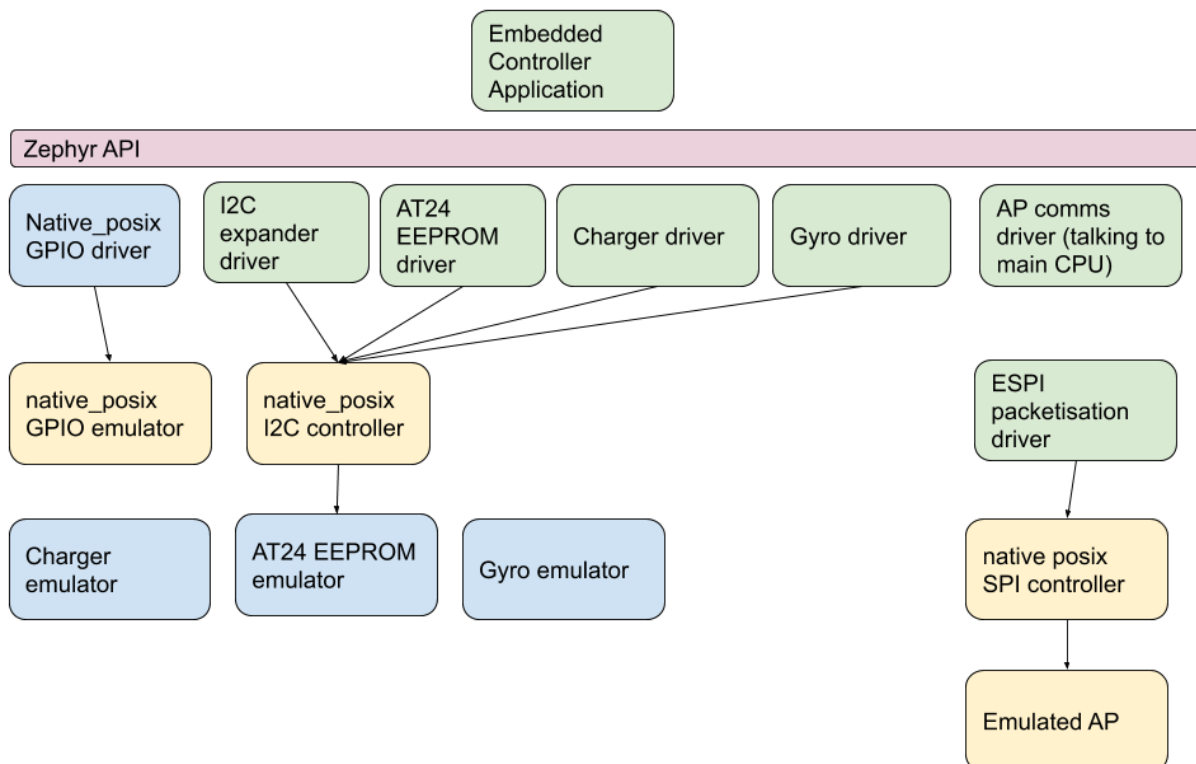

Below that are peripheral drivers, such as the AT24 EEPROM driver. We can test peripheral drivers using an emulation driver connected via a native\_posix I2C controller/emulator which passes I2C traffic from the AT24 driver to the AT24 simulator.

Separately we can test the STM32 and NXP I2C drivers on real hardware using API tests. These require some sort of device attached to the bus, but with this, we can validate much of the driver functionality.

Putting the two together, we can test the application and peripheral code entirely on native\_posix. Since we know that the I2C driver on the real hardware works, we should expect the application and peripheral drivers to work on the real hardware also.

Using the above framework we can test an entire application (e.g. Embedded Controller) on native\_posix using emulators for all non-chip drivers:

The ‘real’ code is shown in green. The Zephyr emulation-framework code is shown in yellow. The blue boxes are the extra code we have to write to emulate the peripherals.

With this approach we can:

- Write individual tests for each driver (green), covering all failure modes, error conditions, etc.
- Ensure 100% test coverage for drivers (green)
- Write tests for combinations of drivers, such as GPIOs provided by an I2C GPIO expander driver talking over an I2C bus, with the GPIOs controlling a charger. All of this can work in the emulated environment or on real hardware.
- Write a complex application that ties together all of these pieces and runs on native\_posix. We can develop on a host, use source-level debugging, etc.
- Transfer the application to any board which provides the required features (e.g. I2C, enough GPIOs), by adding Kconfig and devicetree fragments.

### 8.12.3 Available emulators

Zephyr includes the following emulators:

- EEPROM, which uses a file as the EEPROM contents
- I2C emulator driver, allowing drivers to be connected to an emulator so that tests can be performed without access to the real hardware
- SPI emulator driver, which does the same for SPI
- eSPI emulator driver, which does the same for eSPI. The emulator is being developed to support more functionalities.

A GPIO emulator is planned but is not yet complete.

#### 8.12.4 Samples

Here are some examples present in Zephyr:

1. Bosche BMI160 sensor driver connected via both I2C and SPI to an emulator:

```
west build -b native_posix tests/drivers/sensor/accel/
```

2. Simple test of the EEPROM emulator:

```
west build -b native_posix tests/drivers/eeprom
```

3. The same test has a second EEPROM which is an Atmel AT24 EEPROM driver connected via I2C an emulator:

```
west build -b native_posix tests/drivers/eeprom
```

### 8.13 Modules (External projects)

Zephyr relies on the source code of several externally maintained projects in order to avoid reinventing the wheel and to reuse as much well-established, mature code as possible when it makes sense. In the context of Zephyr's build system those are called *modules*. These modules must be integrated with the Zephyr build system, as described in more detail in other sections on this page.

To be classified as a candidate for being included in the default list of modules, an external project is required to have its own life-cycle outside the Zephyr Project, that is, reside in its own repository, and have its own contribution and maintenance workflow and release process. Zephyr modules should not contain code that is written exclusively for Zephyr. Instead, such code should be contributed to the main zephyr tree.

Modules to be included in the default manifest of the Zephyr project need to provide functionality or features endorsed and approved by the project Technical Steering Committee and should comply with the [module licensing requirements](#) and [contribution guidelines](#). They should also have a Zephyr developer that is committed to maintain the module codebase.

Zephyr depends on several categories of modules, including but not limited to:

- Debugger integration
- Silicon vendor Hardware Abstraction Layers (HALs)
- Cryptography libraries
- File Systems
- Inter-Process Communication (IPC) libraries

This page summarizes a list of policies and best practices which aim at better organizing the workflow in Zephyr modules.

### 8.13.1 Module Repositories

- All modules included in the default manifest shall be hosted in repositories under the zephyrproject-rtos GitHub organization.
- The module repository codebase shall include a *module.yml* file in a *zephyr/* folder at the root of the repository.
- Module repository names should follow the convention of using lowercase letters and dashes instead of underscores. This rule will apply to all new module repositories, except for repositories that are directly tracking external projects (hosted in Git repositories); such modules may be named as their external project counterparts.

---

**Note:** Existing module repositories that do not conform to the above convention do not need to be renamed to comply with the above convention.

---

- Modules should use “zephyr” as the default name for the repository main branch. Branches for specific purposes, for example, a module branch for an LTS Zephyr version, shall have names starting with the ‘zephyr\_’ prefix.
- If the module has an external (upstream) project repository, the module repository should preserve the upstream repository folder structure.

---

**Note:** It is not required in module repositories to maintain a ‘master’ branch mirroring the master branch of the external repository. It is not recommended as this may generate confusion around the module’s main branch, which should be ‘zephyr’.

---

#### Synchronizing with upstream

It is preferred to synchronize a module repository with the latest stable release of the corresponding external project. It is permitted, however, to update a Zephyr module repository with the latest development branch tip, if this is required to get important updates in the module codebase. When synchronizing a module with upstream it is mandatory to document the rationale for performing the particular update.

**Requirements for allowed practices** Changes to the main branch of a module repository, including synchronization with upstream code base, may only be applied via pull requests. These pull requests shall be *verifiable* by Zephyr CI and *mergeable* (e.g. with the *Rebase and merge*, or *Create a merge commit* option using Github UI). This ensures that the incoming changes are always **reviewable**, and the *downstream* module repository history is incremental (that is, existing commits, tags, etc. are always preserved). This policy also allows to run Zephyr CI, git lint, identity, and license checks directly on the set of changes that are to be brought into the module repository.

---

**Note:** Force-pushing to a module’s main branch is not allowed.

---

**Allowed practices** The following practices conform to the above requirements and should be followed in all modules repositories. It is up to the module code owner to select the preferred synchronization practice, however, it is required that the selected practice is consistently followed in the respective module repository.

**Updating modules with a diff from upstream:** Upstream changes brought as a single *snapshot* commit (manual diff) in a pull request against the module’s main branch, which may be merged using the *Rebase & merge* operation. This approach is simple and should be applicable to all modules with the downside of supressing the upstream history in the module repository.

---

**Note:** The above practice is the only allowed practice in modules where the external project is not hosted in an upstream Git repository.

---

The commit message is expected to identify the upstream project URL, the version to which the module is updated (upstream version, tag, commit SHA, if applicable, etc.), and the reason for the doing the update.

**Updating modules by merging the upstream branch:** Upstream changes brought in by performing a Git merge of the intended upstream branch (e.g. main branch, latest release branch, etc.) submitting the result in pull request against the module main branch, and merging the pull request using the *Create a merge commit* operation. This approach is applicable to modules with an upstream project Git repository. The main advantages of this approach is that the upstream repository history (that is, the original commit SHAs) is preserved in the module repository. The downside of this approach is that two additional merge commits are generated in the downstream main branch.

## 8.13.2 Contributing to Zephyr modules

### Individual Roles & Responsibilities

To facilitate management of Zephyr module repositories, the following individual roles are defined.

**Administrator:** Each Zephyr module shall have an administrator who is responsible for managing access to the module repository, for example, for adding individuals as Collaborators in the repository at the request of the module owner. Module administrators are members of the Administrators team, that is a group of project members with admin rights to module GitHub repositories.

**Module owner:** Each module shall have a module code owner. Module owners will have the overall responsibility of the contents of a Zephyr module repository. In particular, a module owner will:

- coordinate code reviewing in the module repository
- be the default assignee in pull-requests against the repository's main branch
- request additional collaborators to be added to the repository, as they see fit
- regularly synchronize the module repository with its upstream counterpart following the policies described in [Synchronizing with upstream](#)
- be aware of security vulnerability issues in the external project and update the module repository to include security fixes, as soon as the fixes are available in the upstream code base
- list any known security vulnerability issues, present in the module codebase, in Zephyr release notes.

---

**Note:** Module owners are not required to be Zephyr [Maintainers](#).

---

**Merger:** The Zephyr Release Engineering team has the right and the responsibility to merge approved pull requests in the main branch of a module repository.

### Maintaining the module codebase

Updates in the zephyr main tree, for example, in public Zephyr APIs, may require patching a module's codebase. The responsibility for keeping the module codebase up to date is shared between the **contributor** of such updates in Zephyr and the module **owner**. In particular:

- the contributor of the original changes in Zephyr is required to submit the corresponding changes that are required in module repositories, to ensure that Zephyr CI on the pull request with the original changes, as well as the module integration testing are successful.

- the module owner has the overall responsibility for synchronizing and testing the module codebase with the zephyr main tree. This includes occasional advanced testing of the module's codebase in addition to the testing performed by Zephyr's CI. The module owner is required to fix issues in the module's codebase that have not been caught by Zephyr pull request CI runs.

### Contributing changes to modules

Submitting and merging changes directly to a module's codebase, that is, before they have been merged in the corresponding external project repository, should be limited to:

- changes required due to updates in the zephyr main tree
- urgent changes that should not wait to be merged in the external project first, such as fixes to security vulnerabilities.

Non-trivial changes to a module's codebase, including changes in the module design or functionality should be discouraged, if the module has an upstream project repository. In that case, such changes shall be submitted to the upstream project, directly.

[Submitting changes to modules](#) describes in detail the process of contributing changes to module repositories.

**Contribution guidelines** Contributing to Zephyr modules shall follow the generic project [Contribution guidelines](#).

**Pull Requests:** may be merged with minimum of 2 approvals, including an approval by the PR assignee. In addition to this, pull requests in module repositories may only be merged if the introduced changes are verified with Zephyr CI tools, as described in more detail in other sections on this page.

The merging of pull requests in the main branch of a module repository must be coupled with the corresponding manifest file update in the zephyr main tree.

**Issue Reporting:** GitHub issues are intentionally disabled in module repositories, in favor of a centralized policy for issue reporting. Tickets concerning, for example, bugs or enhancements in modules shall be opened in the main zephyr repository. Issues should be appropriately labeled using GitHub labels corresponding to each module, where applicable.

---

**Note:** It is allowed to file bug reports for zephyr modules to track the corresponding upstream project bugs in Zephyr. These bug reports shall not affect the [Release Quality Criteria](#).

---

### 8.13.3 Licensing requirements and policies

All source files in a module's codebase shall include a license header, unless the module repository has **main license file** that covers source files that do not include license headers.

Main license files shall be added in the module's codebase by Zephyr developers, only if they exist as part of the external project, and they contain a permissive OSI-compliant license. Main license files should preferably contain the full license text instead of including an SPDX license identifier. If multiple main license files are present it shall be made clear which license applies to each source file in a module's codebase.

Individual license headers in module source files supersede the main license.

Any new content to be added in a module repository will require to have license coverage.

---

**Note:** Zephyr recommends conveying module licensing via individual license headers and main license files. This not a hard requirement; should an external project have its own practice of conveying how licensing applies in the module's codebase (for example, by having

a single or multiple main license files), this practice may be accepted by and be referred to in the Zephyr module, as long as licensing requirements, for example OSI compliance, are satisfied.

---

## License policies

When creating a module repository a developer shall:

- import the main license files, if they exist in the external project, and
- document (for example in the module README or .yaml file) the default license that covers the module's codebase.

**License checks** License checks (via CI tools) shall be enabled on every pull request that adds new content in module repositories.

### 8.13.4 Documentation requirements

All Zephyr module repositories shall include an .rst file documenting:

- the scope and the purpose of the module
- how the module integrates with Zephyr
- the owner of the module repository
- synchronization information with the external project (commit, SHA, version etc.)
- licensing information as described in [Licensing requirements and policies](#).

The file shall be required for the inclusion of the module and the contained information should be kept up to date.

### 8.13.5 Testing requirements

All Zephyr modules should provide some level of **integration** testing, ensuring that the integration with Zephyr works correctly. Integration tests:

- may be in the form of a minimal set of samples and tests that reside in the zephyr main tree
- should verify basic usage of the module (configuration, functional APIs, etc.) that is integrated with Zephyr.
- shall be built and executed (for example in QEMU) as part of twister runs in pull requests that introduce changes in module repositories.

---

**Note:** New modules, that are candidates for being included in the Zephyr default manifest, shall provide some level of integration testing.

---

---

**Note:** Vendor HALs are implicitly tested via Zephyr tests built or executed on target platforms, so they do not need to provide integration tests.

---

The purpose of integration testing is not to provide functional verification of the module; this should be part of the testing framework of the external project.

Certain external projects provide test suites that reside in the upstream testing infrastructure but are written explicitly for Zephyr. These tests may (but are not required to) be part of the Zephyr test framework.

### 8.13.6 Deprecating and removing modules

Modules may be deprecated for reasons including, but not limited to:

- Lack of maintainership in the module
- Licensing changes in the external project
- Codebase becoming obsolete

The module information shall indicate whether a module is deprecated and the build system shall issue a warning when trying to build Zephyr using a deprecated module.

Deprecated modules may be removed from the Zephyr default manifest after 2 Zephyr releases.

---

**Note:** Repositories of removed modules shall remain accessible via their original URL, as they are required by older Zephyr versions.

---

### 8.13.7 Integrate modules in Zephyr build system

The build system variable `ZEPHYR_MODULES` is a [CMake list](#) of absolute paths to the directories containing Zephyr modules. These modules contain `CMakeLists.txt` and `Kconfig` files describing how to build and configure them, respectively. Module `CMakeLists.txt` files are added to the build using CMake's `add_subdirectory()` command, and the `Kconfig` files are included in the build's `Kconfig` menu tree.

If you have [west](#) installed, you don't need to worry about how this variable is defined unless you are adding a new module. The build system knows how to use `west` to set `ZEPHYR_MODULES`. You can add additional modules to this list by setting the `ZEPHYR_EXTRA_MODULES` CMake variable or by adding a `ZEPHYR_EXTRA_MODULES` line to `.zephyrrc` (See the section on [Setting Variables](#) for more details). This can be useful if you want to keep the list of modules found with `west` and also add your own.

---

**Note:** If the module `F00` is provided by [west](#) but also given with `-DZEPHYR_EXTRA_MODULES=/<path>/foo then the module given by the command line variable ZEPHYR_EXTRA_MODULES will take precedence. This allows you to use a custom version of F00 when building and still use other Zephyr modules provided by west. This can for example be useful for special test purposes.`

---

See [Basics](#) for more on `west` workspaces.

Finally, you can also specify the list of modules yourself in various ways, or not use modules at all if your application doesn't need them.

### 8.13.8 Module `yaml` file description

A module can be described using a file named `zephyr/module.yaml`. The format of `zephyr/module.yaml` is described in the following:

#### Module name

Each Zephyr module is given a name by which it can be referred to in the build system.

The name may be specified in the `zephyr/module.yaml` file:

```
name: <name>
```

In CMake the location of the Zephyr module can then be referred to using the CMake variable `ZEPHYR_<MODULE_NAME>_MODULE_DIR` and the variable `ZEPHYR_<MODULE_NAME>_CMAKE_DIR` holds the location of the directory containing the module's `CMakeLists.txt` file.

---

**Note:** When used for CMake and Kconfig variables, all letters in module names are converted to uppercase and all non-alphanumeric characters are converted to underscores (`_`). As example, the module `foo-bar` must be referred to as `ZEPHYR_FOO_BAR_MODULE_DIR` in CMake and Kconfig.

---

Here is an example for the Zephyr module `foo`:

```
name: foo
```

---

**Note:** If the `name` field is not specified then the Zephyr module name will be set to the name of the module folder. As example, the Zephyr module located in `<workspace>/modules/bar` will use `bar` as its module name if nothing is specified in `zephyr/module.yml`.

---

### Module integration files (in-module)

Inclusion of build files, `CMakeLists.txt` and `Kconfig`, can be described as:

```
build:
  cmake: <cmake-directory>
  kconfig: <directory>/Kconfig
```

The `cmake: <cmake-directory>` part specifies that `<cmake-directory>` contains the `CMakeLists.txt` to use. The `kconfig: <directory>/Kconfig` part specifies the `Kconfig` file to use. Neither is required: `cmake` defaults to `zephyr`, and `kconfig` defaults to `zephyr/Kconfig`.

Here is an example `module.yml` file referring to `CMakeLists.txt` and `Kconfig` files in the root directory of the module:

```
build:
  cmake: .
  kconfig: Kconfig
```

### Build system integration

When a module has a `module.yml` file, it will automatically be included into the Zephyr build system. The path to the module is then accessible through Kconfig and CMake variables.

In both Kconfig and CMake, the variable `ZEPHYR_<MODULE_NAME>_MODULE_DIR` contains the absolute path to the module.

In CMake, `ZEPHYR_<MODULE_NAME>_CMAKE_DIR` contains the absolute path to the directory containing the `CMakeLists.txt` file that is included into CMake build system. This variable's value is empty if the `module.yml` file does not specify a `CMakeLists.txt`.

To read these variables for a Zephyr module named `foo`:

- In CMake: use `${ZEPHYR_FOO_MODULE_DIR}` for the module's top level directory, and `${ZEPHYR_FOO_CMAKE_DIR}` for the directory containing its `CMakeLists.txt`
- In Kconfig: use `$(ZEPHYR_FOO_MODULE_DIR)` for the module's top level directory

Notice how a lowercase module name `foo` is capitalized to `FOO` in both CMake and Kconfig.

These variables can also be used to test whether a given module exists. For example, to verify that `foo` is the name of a Zephyr module:

```
if(ZEPHYR_FOO_MODULE_DIR)
    # Do something if FOO exists.
endif()
```

In Kconfig, the variable may be used to find additional files to include. For example, to include the file `some/Kconfig` in module `foo`:

```
source "${ZEPHYR_FOO_MODULE_DIR}/some/Kconfig"
```

During CMake processing of each Zephyr module, the following two variables are also available:

- the current module's top level directory: `${ZEPHYR_CURRENT_MODULE_DIR}`
- the current module's CMakeLists.txt directory: `${ZEPHYR_CURRENT_CMAKE_DIR}`

This removes the need for a Zephyr module to know its own name during CMake processing. The module can source additional CMake files using these `CURRENT` variables. For example:

```
include("${ZEPHYR_CURRENT_MODULE_DIR}/cmake/code.cmake)
```

It is possible to append values to a Zephyr CMake list variable from the module's first CMakeLists.txt file. To do so, append the value to the list and then set the list in the `PARENT_SCOPE` of the CMakeLists.txt file. For example, to append `bar` to the `FOO_LIST` variable in the Zephyr CMakeLists.txt scope:

```
list(APPEND FOO_LIST bar)
set(FOO_LIST ${FOO_LIST} PARENT_SCOPE)
```

An example of a Zephyr list where this is useful is when adding additional directories to the `SYSCALL_INCLUDE_DIRS` list.

## Zephyr module dependencies

A Zephyr module may be dependent on other Zephyr modules to be present in order to function correctly. Or it might be that a given Zephyr module must be processed after another Zephyr module, due to dependencies of certain CMake targets.

Such a dependency can be described using the `depends` field.

```
build:
  depends:
    - <module>
```

Here is an example for the Zephyr module `foo` that is dependent on the Zephyr module `bar` to be present in the build system:

```
name: foo
build:
  depends:
    - bar
```

This example will ensure that `bar` is present when `foo` is included into the build system, and it will also ensure that `bar` is processed before `foo`.

### Module integration files (external)

Module integration files can be located externally to the Zephyr module itself. The `MODULE_EXT_ROOT` variable holds a list of roots containing integration files located externally to Zephyr modules.

**Module integration files in Zephyr** The Zephyr repository contain `CMakeLists.txt` and `Kconfig` build files for certain known Zephyr modules.

Those files are located under

```
<ZEPHYR_BASE>
└─ modules
    └─ <module_name>
        ├── CMakeLists.txt
        └── Kconfig
```

**Module integration files in a custom location** You can create a similar `MODULE_EXT_ROOT` for additional modules, and make those modules known to Zephyr build system.

Create a `MODULE_EXT_ROOT` with the following structure

```
<MODULE_EXT_ROOT>
└─ modules
    ├── modules.cmake
    └─ <module_name>
        ├── CMakeLists.txt
        └── Kconfig
```

and then build your application by specifying `-DMODULE_EXT_ROOT` parameter to the CMake build system. The `MODULE_EXT_ROOT` accepts a CMake list of roots as argument.

A Zephyr module can automatically be added to the `MODULE_EXT_ROOT` list using the module description file `zephyr/module.yml`, see [Build settings](#).

---

**Note:** `ZEPHYR_BASE` is always added as a `MODULE_EXT_ROOT` with the lowest priority. This allows you to overrule any integration files under `<ZEPHYR_BASE>/modules/<module_name>` with your own implementation your own `MODULE_EXT_ROOT`.

---

The `modules.cmake` file must contain the logic that specifies the integration files for Zephyr modules via specifically named CMake variables.

To include a module's CMake file, set the variable `ZEPHYR_<MODULE_NAME>_CMAKE_DIR` to the path containing the CMake file.

To include a module's Kconfig file, set the variable `ZEPHYR_<MODULE_NAME>_KCONFIG` to the path to the Kconfig file.

The following is an example on how to add support the the `FOO` module.

Create the following structure

```
<MODULE_EXT_ROOT>
└─ modules
    ├── modules.cmake
    └─ foo
        ├── CMakeLists.txt
        └── Kconfig
```

and inside the `modules.cmake` file, add the following content

```
set(ZEPHYR_FOO_CMAKE_DIR ${CMAKE_CURRENT_LIST_DIR}/foo)
set(ZEPHYR_FOO_KCONFIG   ${CMAKE_CURRENT_LIST_DIR}/foo/Kconfig)
```

**Module integration files (zephyr/module.yml)** The module description file `zephyr/module.yml` can be used to specify that the build files, `CMakeLists.txt` and `Kconfig`, are located in a [Module integration files \(external\)](#).

Build files located in a `MODULE_EXT_ROOT` can be described as:

```
build:
  cmake-ext: True
  kconfig-ext: True
```

This allows control of the build inclusion to be described externally to the Zephyr module.

The Zephyr repository itself is always added as a Zephyr module ext root.

### Build settings

It is possible to specify additional build settings that must be used when including the module into the build system.

All root settings are relative to the root of the module.

Build settings supported in the `module.yml` file are:

- `board_root`: Contains additional boards that are available to the build system. Additional boards must be located in a `<board_root>/boards` folder.
- `dts_root`: Contains additional dts files related to the architecture/soc families. Additional dts files must be located in a `<dts_root>/dts` folder.
- `soc_root`: Contains additional SoCs that are available to the build system. Additional SoCs must be located in a `<soc_root>/soc` folder.
- `arch_root`: Contains additional architectures that are available to the build system. Additional architectures must be located in a `<arch_root>/arch` folder.
- `module_ext_root`: Contains `CMakeLists.txt` and `Kconfig` files for Zephyr modules, see also [Module integration files \(external\)](#).

Example of a `module.yml` file containing additional roots, and the corresponding file system layout.

```
build:
  settings:
    board_root: .
    dts_root: .
    soc_root: .
    arch_root: .
    module_ext_root: .
```

requires the following folder structure:

```
<zephyr-module-root>
├── arch
├── boards
├── dts
├── modules
└── soc
```

## Twister (Test Runner)

To execute both tests and samples available in modules, the Zephyr test runner (twister) should be pointed to the directories containing those samples and tests. This can be done by specifying the path to both samples and tests in the `zephyr/module.yml` file. Additionally, if a module defines out of tree boards, the module file can point twister to the path where those files are maintained in the module. For example:

```
build:
  cmake: .
samples:
  - samples
tests:
  - tests
boards:
  - boards
```

## Module Inclusion

**Using West** If west is installed and `ZEPHYR_MODULES` is not already set, the build system finds all the modules in your west installation and uses those. It does this by running `west list` to get the paths of all the projects in the installation, then filters the results to just those projects which have the necessary module metadata files.

Each project in the `west list` output is tested like this:

- If the project contains a file named `zephyr/module.yml`, then the content of that file will be used to determine which files should be added to the build, as described in the previous section.
- Otherwise (i.e. if the project has no `zephyr/module.yml`), the build system looks for `zephyr/CMakeLists.txt` and `zephyr/Kconfig` files in the project. If both are present, the project is considered a module, and those files will be added to the build.
- If neither of those checks succeed, the project is not considered a module, and is not added to `ZEPHYR_MODULES`.

**Without West** If you don't have west installed or don't want the build system to use it to find Zephyr modules, you can set `ZEPHYR_MODULES` yourself using one of the following options. Each of the directories in the list must contain either a `zephyr/module.yml` file or the files `zephyr/CMakeLists.txt` and `Kconfig`, as described in the previous section.

1. At the CMake command line, like this:

```
cmake -DZEPHYR_MODULES=<path-to-module1>[;<path-to-module2>[...]] ...
```

2. At the top of your application's top level `CMakeLists.txt`, like this:

```
set(ZEPHYR_MODULES <path-to-module1> <path-to-module2> [...])
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
```

If you choose this option, make sure to set the variable **before** calling `find_package(Zephyr ...)`, as shown above.

3. In a separate CMake script which is pre-loaded to populate the CMake cache, like this:

```
# Put this in a file with a name like "zephyr-modules.cmake"
set(ZEPHYR_MODULES <path-to-module1> <path-to-module2>
  CACHE STRING "pre-cached modules")
```

You can tell the build system to use this file by adding `-C zephyr-modules.cmake` to your CMake command line.

**Not using modules** If you don't have west installed and don't specify `ZEPHYR_MODULES` yourself, then no additional modules are added to the build. You will still be able to build any applications that don't require code or Kconfig options defined in an external repository.

### 8.13.9 Submitting changes to modules

When submitting new or making changes to existing modules the main repository Zephyr needs a reference to the changes to be able to verify the changes. In the main tree this is done using revisions. For code that is already merged and part of the tree we use the commit hash, a tag, or a branch name. For pull requests however, we require specifying the pull request number in the revision field to allow building the zephyr main tree with the changes submitted to the module.

To avoid merging changes to master with pull request information, the pull request should be marked as DNM (Do Not Merge) or preferably a draft pull request to make sure it is not merged by mistake and to allow for the module to be merged first and be assigned a permanent commit hash. Once the module is merged, the revision will need to be changed either by the submitter or by the maintainer to the commit hash of the module which reflects the changes.

Note that multiple and dependent changes to different modules can be submitted using exactly the same process. In this case you will change multiple entries of all modules that have a pull request against them.

#### Process for submitting a new module

Please follow the process in [Submission and review process](#) and obtain the TSC approval to integrate the external source code as a module

If the request is approved, a new repository will be created by the project team and initialized with basic information that would allow submitting code to the module project following the project contribution guidelines.

If a module is maintained as a fork of another project on Github, the Zephyr module related files and changes in relation to upstream need to be maintained in a special branch named `zephyr`.

Maintainers from the Zephyr project will create the repository and initialize it. You will be added as a collaborator in the new repository. Submit the module content (code) to the new repository following the guidelines described [here](#), and then add a new entry to the `west.yml` with the following information:

```
- name: <name of repository>
  path: <path to where the repository should be cloned>
  revision: <ref pointer to module pull request>
```

For example, to add `my_module` to the manifest:

```
- name: my_module
  path: modules/lib/my_module
  revision: pull/23/head
```

Where 23 in the example above indicated the pull request number submitted to the `my_module` repository. Once the module changes are reviewed and merged, the revision needs to be changed to the commit hash from the module repository.

### Process for submitting changes to existing modules

1. Submit the changes using a pull request to an existing repository following the [contribution guidelines](#).
2. Submit a pull request changing the entry referencing the module into the `west.yml` of the main Zephyr tree with the following information:

```
- name: <name of repository>
  path: <path to where the repository should be cloned>
  revision: <ref pointer to module pull request>
```

For example, to add `my_module` to the manifest:

```
- name: my_module
  path: modules/lib/my_module
  revision: pull/23/head
```

Where 23 in the example above indicated the pull request number submitted to the `my_module` repository. Once the module changes are reviewed and merged, the revision needs to be changed to the commit hash from the module repository.

## 8.14 Networking

The networking section contains information regarding the network stack of the Zephyr kernel. Use the information to understand the principles behind the operation of the stacks and how they were implemented.

### 8.14.1 Overview

- [Supported Features](#)
- [Source Tree Layout](#)

#### Supported Features

The networking IP stack is modular and highly configurable via build-time configuration options. You can minimize system memory consumption by enabling only those network features required by your application. Almost all features can be disabled if not needed.

- **IPv6** The support for IPv6 is enabled by default. Various IPv6 sub-options can be enabled or disabled depending on networking needs.
  - Developer can set the number of unicast and multicast IPv6 addresses that are active at the same time.
  - The IPv6 address for the device can be set either statically or dynamically using SLAAC (Stateless Address Auto Configuration) ([RFC 4862](#)).
  - The system also supports multiple IPv6 prefixes and the maximum IPv6 prefix count can be configured at build time.
  - The IPv6 neighbor cache can be disabled if not needed, and its size can be configured at build time.
  - The IPv6 neighbor discovery support ([RFC 4861](#)) is enabled by default.

- Multicast Listener Discovery v2 support ([RFC 3810](#)) is enabled by default.
- IPv6 header compression (6lo) is available for IPv6 connectivity for Bluetooth IPSP ([RFC 7668](#)) and IEEE 802.15.4 networks ([RFC 4944](#)).
- **IPv4** The legacy IPv4 is supported by the networking stack. It cannot be used by IEEE 802.15.4 or Bluetooth IPSP as those network technologies support only IPv6. IPv4 can be used in Ethernet based networks. By default IPv4 support is disabled.
  - DHCP (Dynamic Host Configuration Protocol) client is supported ([RFC 2131](#)).
  - The IPv4 address can also be configured manually. Static IPv4 addresses are supported by default.
- **Dual stack support.** The networking stack allows a developer to configure the system to use both IPv6 and IPv4 at the same time.
- **UDP** User Datagram Protocol ([RFC 768](#)) is supported. The developer can send UDP datagrams (client side support) or create a listener to receive UDP packets destined to certain port (server side support).
- **TCP** Transmission Control Protocol ([RFC 793](#)) is supported. Both server and client roles can be used the the application. The amount of TCP sockets that are available to applications can be configured at build time.
- **BSD Sockets API** Support for a subset of a [BSD sockets compatible API](#) is implemented. Both blocking and non-blocking datagram (UDP) and stream (TCP) sockets are supported.
- **Secure Sockets API** Experimental support for TLS/DTLS secure protocols and configuration options for sockets API. Secure functions for the implementation are provided by mbedTLS library.
- **MQTT** Message Queue Telemetry Transport (ISO/IEC PRF 20922) is supported. A sample mqtt-publisher-sample client application for MQTT v3.1.1 is implemented.
- **CoAP** Constrained Application Protocol ([RFC 7252](#)) is supported. Both coap-client-sample and coap-server-sample sample applications are implemented.
- **LWM2M** OMA Lightweight Machine-to-Machine Protocol ([LwM2M specification 1.0.2](#)) is supported via the “Bootstrap”, “Client Registration”, “Device Management & Service Enablement” and “Information Reporting” interfaces. The required core LwM2M objects are implemented as well as several IPSO Smart Objects. lwm2m-client-sample implements the library as an example.
- **DNS** Domain Name Service ([RFC 1035](#)) client functionality is supported. Applications can use the DNS API to query domain name information or IP addresses from the DNS server. Both IPv4 (A) and IPv6 (AAAA) records can be queried. Both multicast DNS (mDNS) ([RFC 6762](#)) and link-local multicast name resolution (LLMNR) ([RFC 4795](#)) are supported.
- **Network Management API.** Applications can use network management API to listen management events generated by core stack when for example IP address is added to the device, or network interface is coming up etc.
- **Multiple Network Technologies.** The Zephyr OS can be configured to support multiple network technologies at the same time simply by enabling them in Kconfig: for example, Ethernet and 802.15.4 support. Note that no automatic IP routing functionality is provided between these technologies. Applications can send data according to their needs to desired network interface.
- **Minimal Copy Network Buffer Management.** It is possible to have minimal copy network data path. This means that the system tries to avoid copying application data when it is sent to the network.
- **Virtual LAN support.** Virtual LANs (VLANs) allow partitioning of physical ethernet networks into logical networks. See [VLAN support](#) for more details.
- **Network traffic classification.** The sent and received network packets can be prioritized depending on application needs. See [traffic classification](#) for more details.
- **Time Sensitive Networking.** The gPTP (generalized Precision Time Protocol) is supported. See [gPTP support](#) for more details.

- **Network shell.** The network shell provides helpers for figuring out network status, enabling/disabling features, and issuing commands like ping or DNS resolving. The net-shell is useful when developing network software. See [network shell](#) for more details.

Additionally these network technologies (link layers) are supported in Zephyr OS v1.7 and later:

- IEEE 802.15.4
- Bluetooth
- Ethernet
- SLIP (IP over serial line). Used for testing with QEMU. It provides ethernet interface to host system (like Linux) and test applications can be run in Linux host and send network data to Zephyr OS device.

### Source Tree Layout

The networking stack source code tree is organized as follows:

`subsys/net/ip/` This is where the IP stack code is located.

`subsys/net/l2/` This is where the IP stack layer 2 code is located. This includes generic support for Bluetooth IPSP adaptation, Ethernet, IEEE 802.15.4 and Wi-Fi.

`subsys/net/lib/` Application-level protocols (DNS, MQTT, etc.) and additional stack components (BSD Sockets, etc.).

`include/net/` Public API header files. These are the header files applications need to include to use IP networking functionality.

`samples/net/` Sample networking code. This is a good reference to get started with network application development.

`tests/net/` Test applications. These applications are used to verify the functionality of the IP stack, but are not the best source for sample code (see `samples/net` instead).

## 8.14.2 Network Stack Architecture

### Network Packet Processing Statistics

This page describes how to get information about network packet processing statistics inside network stack.

Network stack contains infrastructure to figure out how long the network packet processing takes either in sending or receiving path. There are two Kconfig options that control this. For transmit (TX) path the option is called `:kconfig:CONFIG_NET_PKT_TXTIME_STATS` and for receive (RX) path the options is called `:kconfig:CONFIG_NET_PKT_RXTIME_STATS`. Note that for TX, all kind of network packet statistics is collected. For RX, only UDP, TCP or raw packet type network packet statistics is collected.

After enabling these options, the `net stats` network shell command will show this information:

```
Avg TX net_pkt (11484) time 67 us
Avg RX net_pkt (11474) time 43 us
```

---

**Note:** The values above and below are from emulated qemu\_x86 board and UDP traffic

---

The TX time tells how long it took for network packet from its creation to when it was sent to the network. The RX time tells the time from its creation to when it was passed to the application. The values are in microseconds. The statistics will be collected per traffic class if there are more than one transmit or

receive queues defined in the system. These are controlled by `:kconfig: `CONFIG_NET_TC_TX_COUNT`` and `:kconfig: `CONFIG_NET_TC_RX_COUNT`` options.

If you enable `:kconfig: `CONFIG_NET_PKT_TXTIME_STATS_DETAIL`` or `:kconfig: `CONFIG_NET_PKT_RXTIME_STATS_DETAIL`` options, then additional information for TX or RX network packets are collected when the network packet traverses the IP stack.

After enabling these options, the `net stats` will show this information:

```
Avg TX net_pkt (18902) time 63 us    [0->22->15->23=60 us]
Avg RX net_pkt (18892) time 42 us    [0->9->6->11->13=39 us]
```

The numbers inside the brackets contain information how many microseconds it took for a network packet to go from previous state to next.

In the TX example above, the values are averages over **18902** packets and contain this information:

- Packet was created by application so the time is **0**.
- Packet is about to be placed to transmit queue. The time it took from network packet creation to this state, is **22** microseconds in this example.
- The correct TX thread is invoked, and the packet is read from the transmit queue. It took **15** microseconds from previous state.
- The network packet was just sent and the network stack is about to free the network packet. It took **23** microseconds from previous state.
- In total it took on average **60** microseconds to get the network packet sent. The value **63** tells also the same information, but is calculated differently so there is slight difference because of rounding errors.

In the RX example above, the values are averages over **18892** packets and contain this information:

- Packet was created network device driver so the time is **0**.
- Packet is about to be placed to receive queue. The time it took from network packet creation to this state, is **9** microseconds in this example.
- The correct RX thread is invoked, and the packet is read from the receive queue. It took **6** microseconds from previous state.
- The network packet is then processed and placed to correct socket queue. It took **11** microseconds from previous state.
- The last value tells how long it took from there to the application. Here the value is **13** microseconds.
- In total it took on average **39** microseconds to get the network packet sent. The value **42** tells also the same information, but is calculated differently so there is slight difference because of rounding errors.

The Zephyr network stack is a native network stack specifically designed for Zephyr OS. It consists of layers, each meant to provide certain services to other layers. Network stack functionality is highly configurable via Kconfig options.

- [High level overview of the network stack](#)
- [Network data flow](#)
  - [Data receiving \(RX\)](#)
  - [Data sending \(TX\)](#)
- [Network packet processing statistics](#)

## High level overview of the network stack

The network stack is layered and consists of the following parts:

- **Network Application.** The network application can either use the provided application-level protocol libraries or access the [BSD socket API](#) directly to create a network connection, send or receive data, and close a connection. The application can also use the [network management API](#) to configure the network and set related parameters such as network link options, starting a scan (when applicable), listen network configuration events, etc. The [network interface API](#) can be used to set IP address to a network interface, taking the network interface down, etc.
- **Network Protocols.** This provides implementations for various protocols such as
  - Application-level network protocols like CoAP, LWM2M, and MQTT. See [application protocols chapter](#) for information about them.
  - Core network protocols like IPv6, IPv4, UDP, TCP, ICMPv4, and ICMPv6. You access these protocols by using the [BSD socket API](#).
- **Network Interface Abstraction.** This provides functionality that is common in all the network interfaces, such as setting network interface down, etc. There can be multiple network interfaces in the system. See [network interface overview](#) for more details.
- **L2 Network Technologies.** This provides a common API for sending and receiving data to and from an actual network device. See [L2 overview](#) for more details. These network technologies include [Ethernet](#), [IEEE 802.15.4](#), [Bluetooth](#), [CANBUS](#), etc. Some of these technologies support IPv6 header compression (6Lo), see [RFC 6282](#) for details. For example [ARP](#) for IPv4 is done by the [Ethernet component](#).
- **Network Device Drivers.** The actual low-level device drivers handle the physical sending or receiving of network packets.

## Network data flow

An application typically consists of one or more [threads](#) that execute the application logic. When using the [BSD socket API](#), the following things will happen.

### Data receiving (RX)

1. A network data packet is received by a device driver.
2. The device driver allocates enough network buffers to store the received data. The network packet is placed in the proper RX queue (implemented by [k\\_fifo](#)). By default there is only one receive queue in the system, but it is possible to have up to 8 receive queues. These queues will process incoming packets with different priority. See [Traffic Classification](#) for more details. The receive queues also act as a way to separate the data processing pipeline (bottom-half) as the device driver is running in an interrupt context and it must do its processing as fast as possible.
3. The network packet is then passed to the correct L2 driver. The L2 driver can check if the packet is proper and modify it if needed, e.g. strip L2 header and frame check sequence, etc.
4. The packet is processed by a network interface. The network statistics are collected if enabled by `:kconfig: `CONFIG_NET_STATISTICS``.
5. The packet is then passed to L3 processing. If the packet is IP based, then the L3 layer checks if the packet is a proper IPv6 or IPv4 packet.
6. A socket handler then finds an active socket to which the network packet belongs and puts it in a queue for that socket, in order to separate the networking code from the application. Typically the application is run in userspace context and the network stack is run in kernel context.
7. The application will then receive the data and can process it as needed. The application should have used the [BSD socket API](#) to create a socket that will receive the data.

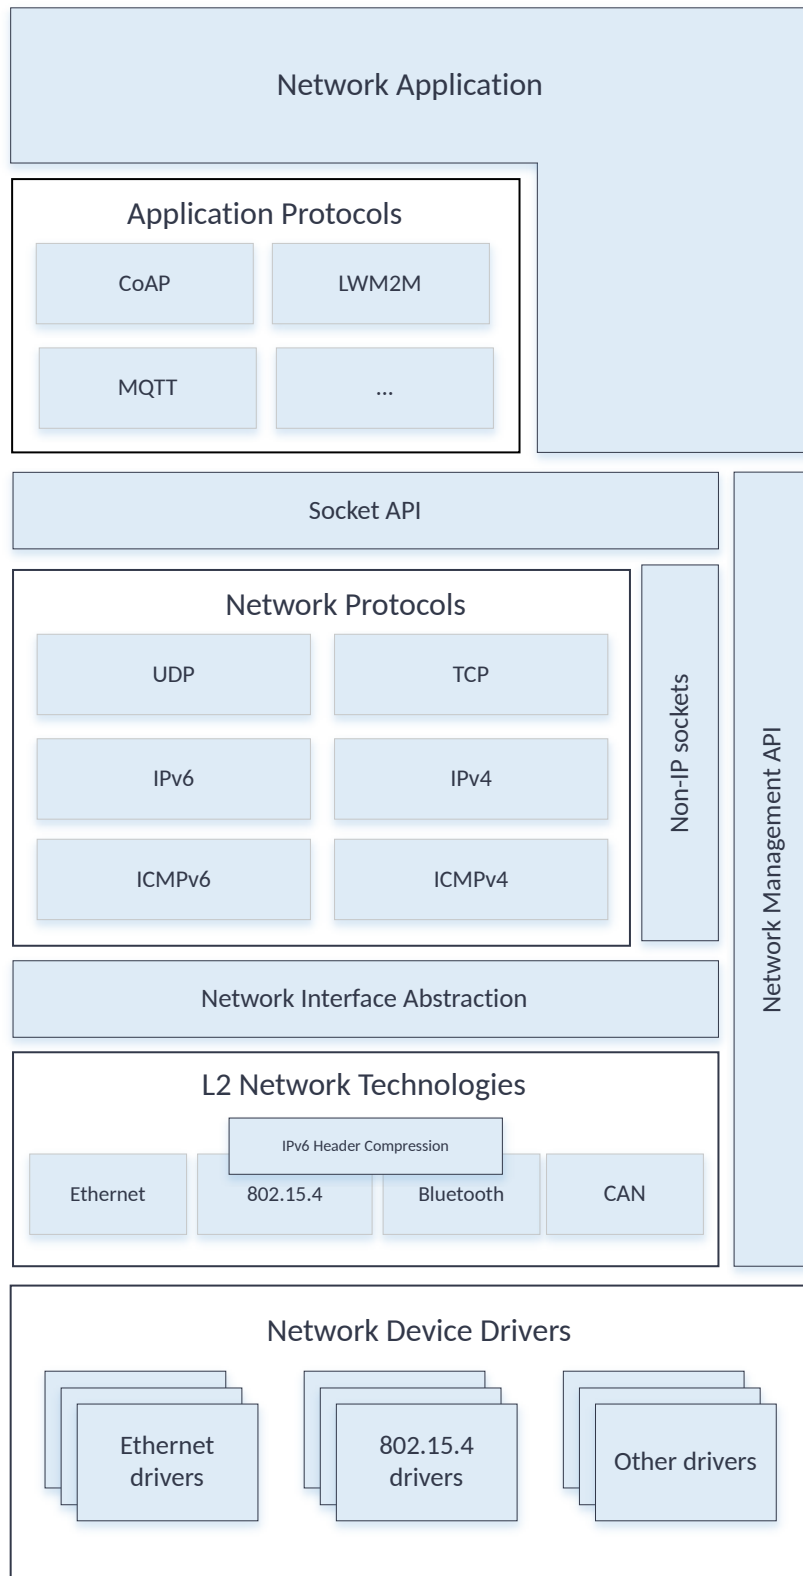

Fig. 8: Network stack overview

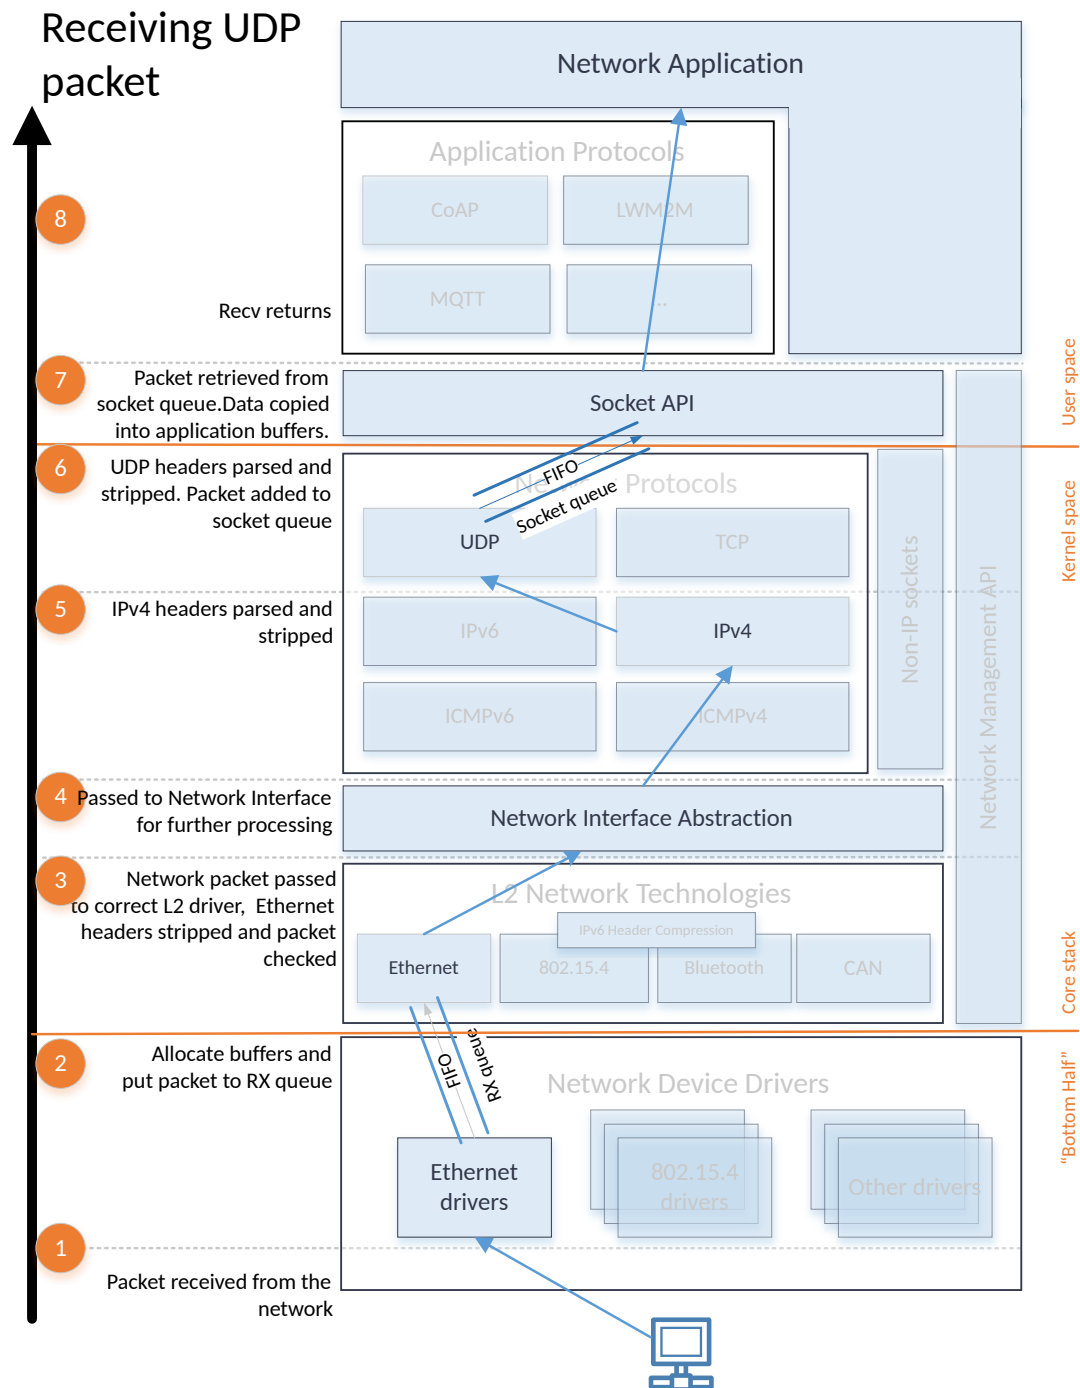

Fig. 9: Network RX data flow

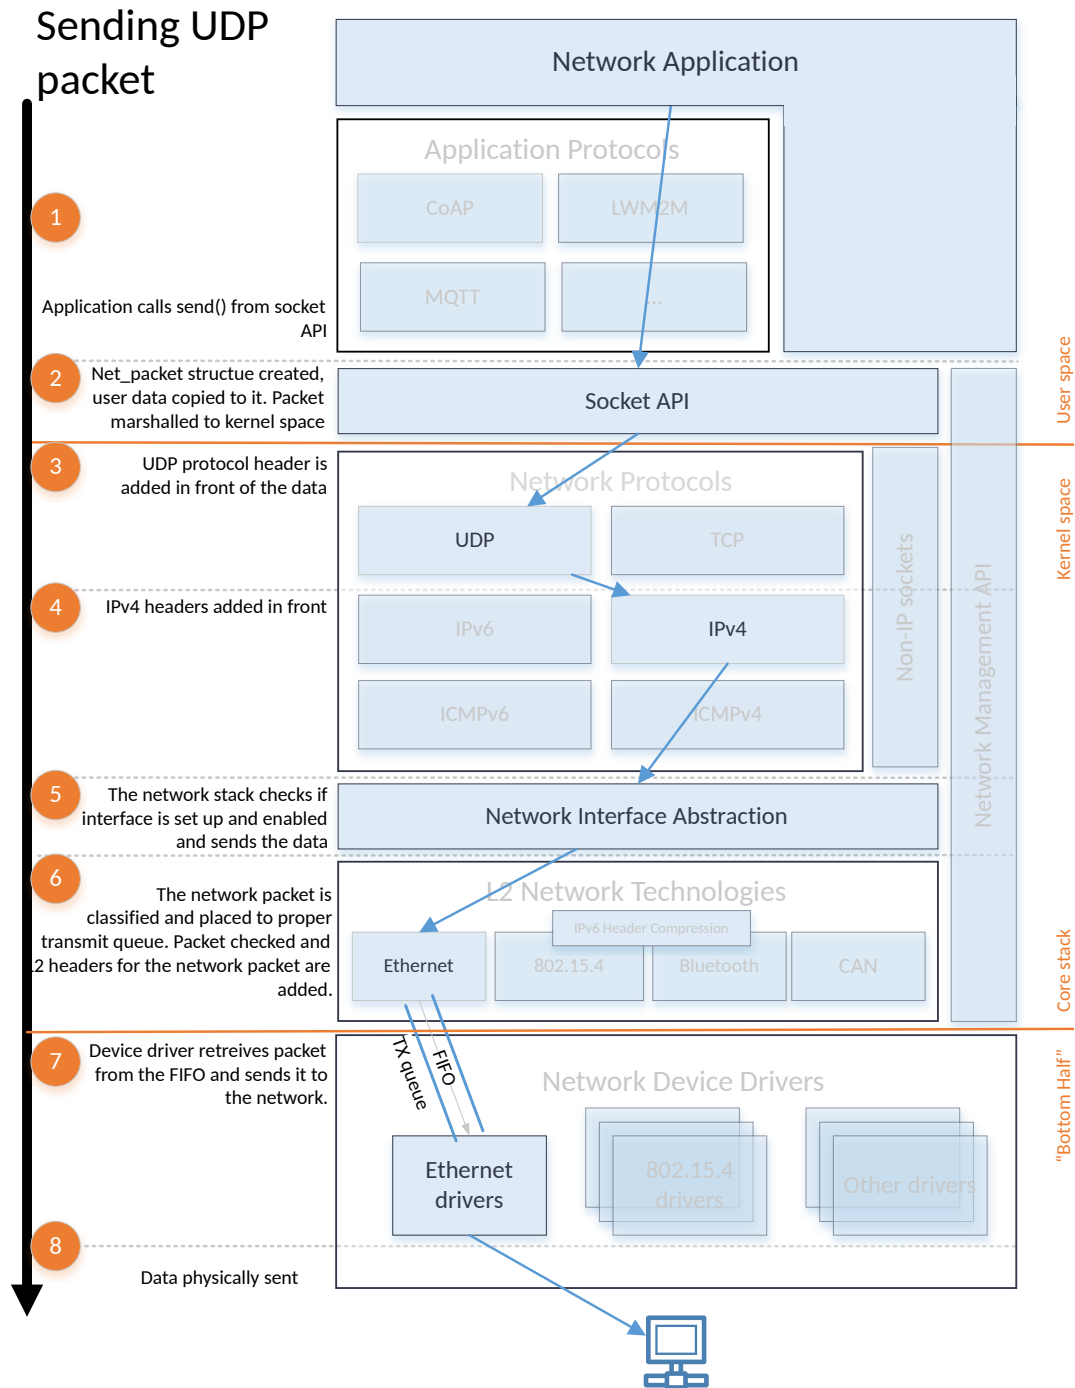

Fig. 10: Network TX data flow

### Data sending (TX)

1. The application should use the [BSD socket API](#) when sending the data.
2. The application data is prepared for sending to kernel space and then copied to internal `net_buf` structures.
3. Depending on the socket type, a protocol header is added in front of the data. For example, if the socket is a UDP socket, then a UDP header is constructed and placed in front of the data.
4. An IP header is added to the network packet for a UDP or TCP packet.
5. The network stack will check that the network interface is properly set for the network packet, and also will make sure that the network interface is enabled before the data is queued to be sent.
6. The network packet is then classified and placed to the proper transmit queue (implemented by [k\\_fifo](#)). By default there is only one transmit queue in the system, but it is possible to have up to 8 transmit queues. These queues will process the sent packets with different priority. See [Traffic Classification](#) for more details. After the transmit packet classification, the packet is checked by the correct L2 layer module. The L2 module will do additional checks for the data and it will also create any L2 headers for the network packet. If everything is ok, the data is given to the network device driver to be sent out.
7. The device driver will send the packet to the network.

Note that in both the TX and RX data paths, the queues ([k\\_fifo](#)'s) form separation points where data is passed from one [thread](#) to another. These [threads](#) might run in different contexts ([kernel](#) vs. [userspace](#)) and with different [priorities](#).

### Network packet processing statistics

See information about network processing statistics [here](#).

## 8.14.3 Network Connectivity API

Applications should use the BSD socket API defined in `include/net/socket.h` to create a connection, send or receive data, and close a connection. The same API can be used when working with UDP or TCP data. See [BSD socket API](#) for more details.

See `sockets-echo-server-sample` and `sockets-echo-client-sample` applications how to create a simple server or client BSD socket based application.

The legacy connectivity API in `include/net/net_context.h` should not be used by applications.

## 8.14.4 Networking with the host system

### Networking with `native_posix` board

- [Prerequisites](#)
- [Basic Setup](#)
  - [Step 1 - Create Ethernet interface](#)
  - [Step 2 - Start app in `native\_posix` board](#)
  - [Step 3 - Connect to console \(optional\)](#)

This page describes how to set up a virtual network between a (Linux) host and a Zephyr application running in a `native_posix` board.

In this example, the `sockets-echo-server-sample` sample application from the Zephyr source distribution is run in `native_posix` board. The Zephyr `native_posix` board instance is connected to a Linux host using a `tuntap` device which is modeled in Linux as an Ethernet network interface.

**Prerequisites** On the Linux Host, fetch the Zephyr `net-tools` project, which is located in a separate Git repository:

```
git clone https://github.com/zephyrproject-rtos/net-tools
```

**Basic Setup** For the steps below, you will need three terminal windows:

- Terminal #1 is terminal window with `net-tools` being the current directory (`cd net-tools`)
- Terminal #2 is your usual Zephyr development terminal, with the Zephyr environment initialized.
- Terminal #3 is the console to the running Zephyr `native_posix` instance (optional).

**Step 1 - Create Ethernet interface** Before starting `native_posix` with network emulation, a network interface should be created.

In terminal #1, type:

```
./net-setup.sh
```

You can tweak the behavior of the `net-setup.sh` script. See various options by running `net-setup.sh` like this:

```
./net-setup.sh --help
```

**Step 2 - Start app in native\_posix board** Build and start the `echo_server` sample application.

In terminal #2, type:

```
west build -b native_posix samples/net/sockets/echo_server
west build -t run
```

**Step 3 - Connect to console (optional)** The console window should be launched automatically when the Zephyr instance is started but if it does not show up, you can manually connect to the console. The `native_posix` board will print a string like this when it starts:

```
UART connected to pseudotty: /dev/pts/5
```

You can manually connect to it like this:

```
screen /dev/pts/5
```

## Networking with QEMU Ethernet

- [Prerequisites](#)
- [Basic Setup](#)

- [Step 1 - Create Ethernet interface](#)
- [Step 2 - Start app in QEMU board](#)

This page describes how to set up a virtual network between a (Linux) host and a Zephyr application running in QEMU.

In this example, the `sockets-echo-server-sample` sample application from the Zephyr source distribution is run in QEMU. The Zephyr instance is connected to a Linux host using a tuntap device which is modeled in Linux as an Ethernet network interface.

**Prerequisites** On the Linux Host, fetch the Zephyr `net-tools` project, which is located in a separate Git repository:

```
git clone https://github.com/zephyrproject-rtos/net-tools
```

**Basic Setup** For the steps below, you will need two terminal windows:

- Terminal #1 is terminal window with `net-tools` being the current directory (`cd net-tools`)
- Terminal #2 is your usual Zephyr development terminal, with the Zephyr environment initialized.

When configuring the Zephyr instance, you must select the correct Ethernet driver for QEMU connectivity:

- For `qemu_x86`, select Intel(R) PRO/1000 Gigabit Ethernet driver Ethernet driver. Driver is called `e1000` in Zephyr source tree.
- For `qemu_cortex_m3`, select TI Stellaris MCU family ethernet driver Ethernet driver. Driver is called `stellaris` in Zephyr source tree.
- For `mps2_an385`, select SMSC911x/9220 Ethernet driver Ethernet driver. Driver is called `smsc911x` in Zephyr source tree.

**Step 1 - Create Ethernet interface** Before starting QEMU with network connectivity, a network interface should be created in the host system.

In terminal #1, type:

```
./net-setup.sh
```

You can tweak the behavior of the `net-setup.sh` script. See various options by running `net-setup.sh` like this:

```
./net-setup.sh --help
```

**Step 2 - Start app in QEMU board** Build and start the `sockets-echo-server-sample` sample application. In this example, the `qemu_x86` board is used.

In terminal #2, type:

```
west build -b qemu_x86 samples/net/sockets/echo_server -- -DOVERLAY_CONFIG=overlay-  
↪e1000.conf  
west build -t run
```

Exit QEMU by pressing CTRL+A x.

## Networking with QEMU

- *Prerequisites*
- *Basic Setup*
  - *Step 1 - Create helper socket*
  - *Step 2 - Start TAP device routing daemon*
  - *Step 3 - Start app in QEMU*
  - *Step 4 - Run apps on host*
  - *Step 5 - Stop supporting daemons*
- *Setting up Zephyr and NAT/masquerading on host to access Internet*
- *Network connection between two QEMU VMs*
  - *Terminal #1:*
  - *Terminal #2:*
- *Running multiple QEMU VMs of the same sample*
  - *Terminal #1:*
  - *Terminal #2:*

This page describes how to set up a virtual network between a (Linux) host and a Zephyr application running in a QEMU virtual machine (built for Zephyr targets such as qemu\_x86 and qemu\_cortex\_m3).

In this example, the sockets-echo-server-sample sample application from the Zephyr source distribution is run in QEMU. The QEMU instance is connected to a Linux host using a serial port, and SLIP is used to transfer data between the Zephyr application and Linux (over a chain of virtual connections).

**Prerequisites** On the Linux Host, fetch the Zephyr net-tools project, which is located in a separate Git repository:

```
git clone https://github.com/zephyrproject-rtos/net-tools
cd net-tools
make
```

**Note:** If you get an error about AX\_CHECK\_COMPILE\_FLAG, install package autoconf-archive package on Debian/Ubuntu.

**Basic Setup** For the steps below, you will need at least 4 terminal windows:

- Terminal #1 is your usual Zephyr development terminal, with the Zephyr environment initialized.
- Terminals #2, #3, and #4 are terminal windows with net-tools being the current directory (cd net-tools)

**Step 1 - Create helper socket** Before starting QEMU with network emulation, a Unix socket for the emulation should be created.

In terminal #2, type:

```
./loop-socat.sh
```

**Step 2 - Start TAP device routing daemon** In terminal #3, type:

```
sudo ./loop-slip-tap.sh
```

For applications requiring DNS, you may need to restart the host's DNS server at this point, as described in [Setting up Zephyr and NAT/masquerading on host to access Internet](#).

**Step 3 - Start app in QEMU** Build and start the echo\_server sample application.

In terminal #1, type:

```
west build -b qemu_x86 samples/net/sockets/echo_server
west build -t run
```

If you see an error from QEMU about unix:/tmp/slip.sock, it means you missed Step 1 above.

**Step 4 - Run apps on host** Now in terminal #4, you can run various tools to communicate with the application running in QEMU.

You can start with pings:

```
ping 192.0.2.1
ping6 2001:db8::1
```

You can use the netcat (“nc”) utility, connecting using UDP:

```
echo foobar | nc -6 -u 2001:db8::1 4242
foobar
```

```
echo foobar | nc -u 192.0.2.1 4242
foobar
```

If echo\_server is compiled with TCP support (now enabled by default for the echo\_server sample, CONFIG\_NET\_TCP=y):

```
echo foobar | nc -6 -q2 2001:db8::1 4242
foobar
```

---

**Note:** Use Ctrl+C to exit.

---

You can also use the telnet command to achieve the above.

**Step 5 - Stop supporting daemons** When you are finished with network testing using QEMU, you should stop any daemons or helpers started in the initial steps, to avoid possible networking or routing problems such as address conflicts in local network interfaces. For example, stop them if you switch from testing networking with QEMU to using real hardware, or to return your host laptop to normal Wi-Fi use.

To stop the daemons, press Ctrl+C in the corresponding terminal windows (you need to stop both loop-slip-tap.sh and loop-socat.sh).

Exit QEMU by pressing CTRL+A x.

**Setting up Zephyr and NAT/masquerading on host to access Internet** To access the internet from a Zephyr application, some additional setup on the host may be required. This setup is common for both application running in QEMU and on real hardware, assuming that a development board is connected to the development host. If a board is connected to a dedicated router, it should not be needed.

To access the internet from a Zephyr application using IPv4, a gateway should be set via DHCP or configured manually. For applications using the “Settings” facility (with the config option `:kconfig: `CONFIG_NET_CONFIG_SETTINGS`` enabled), set the `:kconfig: `CONFIG_NET_CONFIG_MY_IPV4_GW`` option to the IP address of the gateway. For apps not using the “Settings” facility, set up the gateway by calling the `net_if_ipv4_set_gw()` at runtime.

To access the internet from a custom application running in QEMU, NAT (masquerading) should be set up for QEMU’s source address. Assuming 192.0.2.1 is used, the following command should be run as root:

```
iptables -t nat -A POSTROUTING -j MASQUERADE -s 192.0.2.1
```

Additionally, IPv4 forwarding should be enabled on the host, and you may need to check that other firewall (iptables) rules don’t interfere with masquerading. To enable IPv4 forwarding the following command should be run as root:

```
sysctl -w net.ipv4.ip_forward=1
```

Some applications may also require a DNS server. A number of Zephyr-provided samples assume by default that the DNS server is available on the host (IP 192.0.2.2), which, in modern Linux distributions, usually runs at least a DNS proxy. When running with QEMU, it may be required to restart the host’s DNS, so it can serve requests on the newly created TAP interface. For example, on Debian-based systems:

```
service dnsmasq restart
```

An alternative to relying on the host’s DNS server is to use one in the network. For example, 8.8.8.8 is a publicly available DNS server. You can configure it using `:kconfig: `CONFIG_DNS_SERVER1`` option.

**Network connection between two QEMU VMs** Unlike the VM-to-Host setup described above, VM-to-VM setup is automatic. For sample applications that support this mode (such as the `echo_server` and `echo_client` samples), you will need two terminal windows, set up for Zephyr development.

#### Terminal #1:

```
west build -b qemu_x86 samples/net/sockets/echo_server
```

This will start QEMU, waiting for a connection from a client QEMU.

#### Terminal #2:

```
west build -b qemu_x86 samples/net/sockets/echo_client
```

This will start a second QEMU instance, where you should see logging of data sent and received in both.

**Running multiple QEMU VMs of the same sample** If you find yourself wanting to run multiple instances of the same Zephyr sample application, which do not need to talk to each other, use the `QEMU_INSTANCE` argument.

Start socat and tunslip6 manually (instead of using the `loop-xxx.sh` scripts) for as many instances as you want. Use the following as a guide, replacing `MAIN` or `OTHER`.

#### Terminal #1:

```
socat PTY,link=/tmp/slip.devMAIN UNIX-LISTEN:/tmp/slip.sockMAIN
$ZEPHYR_BASE/./net-tools/tunslip6 -t tapMAIN -T -s /tmp/slip.devMAIN \
2001:db8::1/64
# Now run Zephyr
make -Cbuild run QEMU_INSTANCE=MAIN
```

**Terminal #2:**

```
socat PTY,link=/tmp/slip.devOTHER UNIX-LISTEN:/tmp/slip.sockOTHER
$ZEPHYR_BASE/../../net-tools/tunslip6 -t tapOTHER -T -s /tmp/slip.devOTHER \
2001:db8::1/64
make -Cbuild run QEMU_INSTANCE=OTHER
```

## USB Device Networking

- *Basic Setup*
  - *Choosing IP addresses*
  - *Setting IPv4 address and routing*
  - *Setting IPv6 address and routing*
- *Testing connection*

This page describes how to set up networking between a Linux host and a Zephyr application running on USB supported devices.

The board is connected to Linux host using USB cable and provides an Ethernet interface to the host. The sockets-echo-server-sample application from the Zephyr source distribution is run on supported board. The board is connected to a Linux host using a USB cable providing an Ethernet interface to the host.

**Basic Setup** To communicate with the Zephyr application over a newly created Ethernet interface, we need to assign IP addresses and set up a routing table for the Linux host. After plugging a USB cable from the board to the Linux host, the cdc\_ether driver registers a new Ethernet device with a provided MAC address.

You can check that network device is created and MAC address assigned by running dmesg from the Linux host.

```
cdc_ether 1-2.7:1.0 eth0: register 'cdc_ether' at usb-0000:00:01.2-2.7, CDC Ethernet
↪Device, 00:00:5e:00:53:01
```

We need to set it up and assign IP addresses as explained in the following section.

**Choosing IP addresses** To establish network connection to the board we need to choose IP address for the interface on the Linux host.

It make sense to choose addresses in the same subnet we have in Zephyr application. IP addresses usually set in the project configuration files and may be checked also from the shell with following commands. Connect a serial console program (such as puTTY) to the board, and enter this command to the Zephyr shell:

```
shell> net iface

Interface 0xa800e580 (Ethernet)
=====
Link addr  : 00:00:5E:00:53:00
MTU        : 1500
IPv6 unicast addresses (max 2):
    fe80::200:5eff:fe00:5300 autoconf preferred infinite
    2001:db8::1 manual preferred infinite
...
```

(continues on next page)

(continued from previous page)

```
IPv4 unicast addresses (max 1):
    192.0.2.1 manual preferred infinite
```

This command shows that one IPv4 address and two IPv6 addresses have been assigned to the board. We can use either IPv4 or IPv6 for network connection depending on the board network configuration.

Next step is to assign IP addresses to the new Linux host interface, in the following steps enx00005e005301 is the name of the interface on my Linux system.

### Setting IPv4 address and routing

```
# ip address add dev enx00005e005301 192.0.2.2
# ip link set enx00005e005301 up
# ip route add 192.0.2.0/24 dev enx00005e005301
```

### Setting IPv6 address and routing

```
# ip address add dev enx00005e005301 2001:db8::2
# ip link set enx00005e005301 up
# ip -6 route add 2001:db8::/64 dev enx00005e005301
```

**Testing connection** From the host we can test the connection by pinging Zephyr IP address of the board with:

```
$ ping 192.0.2.1
PING 192.0.2.1 (192.0.2.1) 56(84) bytes of data.
64 bytes from 192.0.2.1: icmp_seq=1 ttl=64 time=2.30 ms
64 bytes from 192.0.2.1: icmp_seq=2 ttl=64 time=1.43 ms
64 bytes from 192.0.2.1: icmp_seq=3 ttl=64 time=2.45 ms
...
```

## Networking with QEMU User

- [Introduction](#)
- [Using SLIRP with Zephyr](#)
- [Limitations](#)

This page is intended to serve as a starting point for anyone interested in using QEMU SLIRP with Zephyr.

**Introduction** SLIRP is a network backend which provides the complete TCP/IP stack within QEMU and uses that stack to implement a virtual NAT'd network. As there are no dependencies on the host, SLIRP is simple to setup.

By default, QEMU uses the 10.0.2.X/24 network and runs a gateway at 10.0.2.2. All traffic intended for the host network has to travel through this gateway, which will filter out packets based on the QEMU command line parameters. This gateway also functions as a DHCP server for all GOS, allowing them to be automatically assigned with an IP address starting from 10.0.2.15.

More details about User Networking can be obtained from here: [https://wiki.qemu.org/Documentation/Networking#User\\_Networking\\_.28SLIRP.29](https://wiki.qemu.org/Documentation/Networking#User_Networking_.28SLIRP.29)

**Using SLIRP with Zephyr** In order to use SLIRP with Zephyr, the user has to set the Kconfig option to enable User Networking.

```
CONFIG_NET_QEMU_USER=y
```

Once this configuration option is enabled, all QEMU launches will use SLIRP. In the default configuration, Zephyr only enables User Networking, and does not pass any arguments to it. This means that the Guest will only be able to communicate to the QEMU gateway, and any data intended for the host machine will be dropped by QEMU.

In general, QEMU User Networking can take in a lot of arguments including,

- Information about host/guest port forwarding. This must be provided to create a communication channel between the guest and host.
- Information about network to use. This may be valuable if the user does not want to use the default 10.0.2.X network.
- Tell QEMU to start DHCP server at user-defined IP address.
- ID and other information.

As this information varies with every use case, it is difficult to come up with good defaults that work for all. Therefore, Zephyr Implementation offloads this to the user, and expects that they will provide arguments based on requirements. For this, there is a Kconfig string which can be populated by the user.

```
CONFIG_NET_QEMU_USER_EXTRA_ARGS="net=192.168.0.0/24,hostfwd=tcp::8080-:8080"
```

This option is appended as-is to the QEMU command line. Therefore, any problems with this command line will be reported by QEMU only. Here's what this particular example will do,

- Make QEMU use the 192.168.0.0/24 network instead of the default.
- Enable forwarding of any TCP data received from port 8080 of host to port 8080 of guest, and vice versa.

**Limitations** If the user does not have any specific networking requirements other than the ability to access a web page from the guest, user networking (slirp) is a good choice. However, it has several limitations

- There is a lot of overhead so the performance is poor.
- The guest is not directly accessible from the host or the external network.
- In general, ICMP traffic does not work (so you cannot use ping within a guest).
- As port mappings need to be defined before launching qemu, clients which use dynamically generated ports cannot communicate with external network.
- There is a bug in the SLIRP implementation which filters out all IPv6 packets from the guest. See <https://bugs.launchpad.net/qemu/+bug/1724590> for details. Therefore, IPv6 will not work with User Networking.

## Networking with multiple Zephyr instances

- *Prerequisites*
- *Basic Setup*
  - *Step 1 - Create configuration files*
  - *Step 2 - Create Ethernet interfaces*
  - *Step 3 - Setup network bridging*

---

– *Step 4 - Start Zephyr instances*

---

This page describes how to set up a virtual network between multiple Zephyr instances. The Zephyr instances could be running inside QEMU or could be native\_posix board processes. The Linux host can be used to route network traffic between these systems.

**Prerequisites** On the Linux Host, fetch the Zephyr net-tools project, which is located in a separate Git repository:

```
git clone https://github.com/zephyrproject-rtos/net-tools
```

**Basic Setup** For the steps below, you will need five terminal windows:

- Terminal #1 and #2 are terminal windows with net-tools being the current directory (cd net-tools)
- Terminal #3, where you setup bridging in Linux host
- Terminal #4 and #5 are your usual Zephyr development terminal, with the Zephyr environment initialized.

As there are multiple ways to setup the Zephyr network, the example below uses qemu\_x86 board with e1000 Ethernet controller and native\_posix board to simplify the setup instructions. You can use other QEMU boards and drivers if needed, see [Networking with QEMU Ethernet](#) for details. You can also use two or more native\_posix board Zephyr instances and connect them together.

**Step 1 - Create configuration files** Before starting QEMU with network connectivity, a network interfaces for each Zephyr instance should be created in the host system. The default setup for creating network interface cannot be used here as that is for connecting one Zephyr instance to Linux host.

For Zephyr instance #1, create file called zephyr1.conf to net-tools project, or to some other suitable directory.

```
# Configuration file for setting IP addresses for a network interface.
INTERFACE="$1"
HWADDR="00:00:5e:00:53:11"
IPV6_ADDR_1="2001:db8:100::2"
IPV6_ROUTE_1="2001:db8:100::/64"
IPV4_ADDR_1="198.51.100.2/24"
IPV4_ROUTE_1="198.51.100.0/24"
ip link set dev $INTERFACE up
ip link set dev $INTERFACE address $HWADDR
ip -6 address add $IPV6_ADDR_1 dev $INTERFACE nodad
ip -6 route add $IPV6_ROUTE_1 dev $INTERFACE
ip address add $IPV4_ADDR_1 dev $INTERFACE
ip route add $IPV4_ROUTE_1 dev $INTERFACE > /dev/null 2>&1
```

For Zephyr instance #2, create file called zephyr2.conf to net-tools project, or to some other suitable directory.

```
# Configuration file for setting IP addresses for a network interface.
INTERFACE="$1"
HWADDR="00:00:5e:00:53:22"
IPV6_ADDR_1="2001:db8:200::2"
IPV6_ROUTE_1="2001:db8:200::/64"
IPV4_ADDR_1="203.0.113.2/24"
IPV4_ROUTE_1="203.0.113.0/24"
```

(continues on next page)

(continued from previous page)

```
ip link set dev $INTERFACE up
ip link set dev $INTERFACE address $HWADDR
ip -6 address add $IPV6_ADDR_1 dev $INTERFACE nodad
ip -6 route add $IPV6_ROUTE_1 dev $INTERFACE
ip address add $IPV4_ADDR_1 dev $INTERFACE
ip route add $IPV4_ROUTE_1 dev $INTERFACE > /dev/null 2>&1
```

**Step 2 - Create Ethernet interfaces** The following `net-setup.sh` commands should be typed in `net-tools` directory (`cd net-tools`).

In terminal #1, type:

```
./net-setup.sh -c zephyr1.conf -i zeth.1
```

In terminal #2, type:

```
./net-setup.sh -c zephyr2.conf -i zeth.2
```

**Step 3 - Setup network bridging** In terminal #3, type:

```
sudo brctl addbr zeth-br
sudo brctl addif zeth-br zeth.1
sudo brctl addif zeth-br zeth.2
sudo ifconfig zeth-br up
```

**Step 4 - Start Zephyr instances** In this example we start `sockets-echo-server-sample` and `sockets-echo-client-sample` applications. You can use other applications too as needed.

In terminal #4, if you are using QEMU, type this:

```
west build -d build/server -b qemu_x86 -t run \
  samples/net/sockets/echo_server -- \
  -DOVERLAY_CONFIG=overlay-e1000.conf \
  -DCONFIG_NET_CONFIG_MY_IPV4_ADDR="198.51.100.1\" \
  -DCONFIG_NET_CONFIG_PEER_IPV4_ADDR="203.0.113.1\" \
  -DCONFIG_NET_CONFIG_MY_IPV6_ADDR="2001:db8:100::1\" \
  -DCONFIG_NET_CONFIG_PEER_IPV6_ADDR="2001:db8:200::1\" \
  -DCONFIG_NET_CONFIG_MY_IPV4_GW="203.0.113.1\" \
  -DCONFIG_ETH_QEMU_IFACE_NAME="zeth.1\" \
  -DCONFIG_ETH_QEMU_EXTRA_ARGS="mac=00:00:5e:00:53:01"
```

or if you want to use `native_posix` board, type this:

```
west build -d build/server -b native_posix -t run \
  samples/net/sockets/echo_server -- \
  -DCONFIG_NET_CONFIG_MY_IPV4_ADDR="198.51.100.1\" \
  -DCONFIG_NET_CONFIG_PEER_IPV4_ADDR="203.0.113.1\" \
  -DCONFIG_NET_CONFIG_MY_IPV6_ADDR="2001:db8:100::1\" \
  -DCONFIG_NET_CONFIG_PEER_IPV6_ADDR="2001:db8:200::1\" \
  -DCONFIG_NET_CONFIG_MY_IPV4_GW="203.0.113.1\" \
  -DCONFIG_ETH_NATIVE_POSIX_DRV_NAME="zeth.1\" \
  -DCONFIG_ETH_NATIVE_POSIX_MAC_ADDR="00:00:5e:00:53:01\" \
  -DCONFIG_ETH_NATIVE_POSIX_RANDOM_MAC=n
```

In terminal #5, if you are using QEMU, type this:

```
west build -d build/client -b qemu_x86 -t run \
  samples/net/sockets/echo_client -- \
  -DOVERLAY_CONFIG=overlay-e1000.conf \
  -DCONFIG_NET_CONFIG_MY_IPV4_ADDR="203.0.113.1" \
  -DCONFIG_NET_CONFIG_PEER_IPV4_ADDR="198.51.100.1" \
  -DCONFIG_NET_CONFIG_MY_IPV6_ADDR="2001:db8:200::1" \
  -DCONFIG_NET_CONFIG_PEER_IPV6_ADDR="2001:db8:100::1" \
  -DCONFIG_NET_CONFIG_MY_IPV4_GW="198.51.100.1" \
  -DCONFIG_ETH_QEMU_IFACE_NAME="zeth.2" \
  -DCONFIG_ETH_QEMU_EXTRA_ARGS="mac=00:00:5e:00:53:02"
```

or if you want to use native\_posix board, type this:

```
west build -d build/client -b native_posix -t run \
  samples/net/sockets/echo_client -- \
  -DCONFIG_NET_CONFIG_MY_IPV4_ADDR="203.0.113.1" \
  -DCONFIG_NET_CONFIG_PEER_IPV4_ADDR="198.51.100.1" \
  -DCONFIG_NET_CONFIG_MY_IPV6_ADDR="2001:db8:200::1" \
  -DCONFIG_NET_CONFIG_PEER_IPV6_ADDR="2001:db8:100::1" \
  -DCONFIG_NET_CONFIG_MY_IPV4_GW="198.51.100.1" \
  -DCONFIG_ETH_NATIVE_POSIX_DRV_NAME="zeth.2" \
  -DCONFIG_ETH_NATIVE_POSIX_MAC_ADDR="00:00:5e:00:53:02" \
  -DCONFIG_ETH_NATIVE_POSIX_RANDOM_MAC=n
```

Also if you have firewall enabled in your host, you need to allow traffic between zeth.1, zeth.2 and zeth-br interfaces.

## Networking with QEMU and IEEE 802.15.4

- *Basic Setup*
  - *Step 1 - Compile and start echo-server*
  - *Step 2 - Compile and start echo-client*

This page describes how to set up a virtual network between two QEMUs that are connected together via UART and are running IEEE 802.15.4 link layer between them. Note that this only works in Linux host.

**Basic Setup** For the steps below, you will need two terminal windows:

- Terminal #1 is terminal window with echo-server Zephyr sample application.
- Terminal #2 is terminal window with echo-client Zephyr sample application.

If you want to capture the transferred network data, you must compile the monitor\_15\_4 program in net-tools directory.

Open a terminal window and type:

```
cd $ZEPHYR_BASE/../../net-tools
make monitor_15_4
```

**Step 1 - Compile and start echo-server** In terminal #1, type:

```
west build -b qemu_x86 -d build/server samples/net/sockets/echo_server -- -DOVERLAY_
↪CONFIG=overlay-qemu_802154.conf
west build -t server -d build/server
```

If you want to capture the network traffic between the two QEMUs, type:

```
west build -b qemu_x86 -d build/server samples/net/sockets/echo_server -- -G'Unix_
↪Makefiles' -DOVERLAY_CONFIG=overlay-qemu_802154.conf -DPCAP=capture.pcap
west build -t server -d build/server
```

Note that the make must be used for server target if packet capture option is set in command line. The build/server/capture.pcap file will contain the transferred data.

**Step 2 - Compile and start echo-client** In terminal #2, type:

```
west build -b qemu_x86 -d build/client samples/net/sockets/echo_client -- -DOVERLAY_
↪CONFIG=overlay-qemu_802154.conf
west build -t client -d build/client
```

You should see data passed between the two QEMUs. Exit QEMU by pressing CTRL+A x.

While developing networking software, it is usually necessary to connect and exchange data with the host system like a Linux desktop computer. Depending on what board is used for development, the following options are possible:

- QEMU using SLIP (Serial Line Internet Protocol).
  - Here IP packets are exchanged between Zephyr and the host system via serial port. This is the legacy way of transferring data. It is also quite slow so use it only when necessary. See [Networking with QEMU](#) for details.
- QEMU using built-in Ethernet driver.
  - Here IP packets are exchanged between Zephyr and the host system via QEMU's built-in Ethernet driver. Not all QEMU boards support built-in Ethernet so in some cases, you might need to use the SLIP method for host connectivity. See [Networking with QEMU Ethernet](#) for details.
- QEMU using SLIRP (Qemu User Networking).
  - QEMU User Networking is implemented using “slirp”, which provides a full TCP/IP stack within QEMU and uses that stack to implement a virtual NAT'd network. As this support is built into QEMU, it can be used with any model and requires no admin privileges on the host machine, unlike TAP. However, it has several limitations including performance which makes it less valuable for practical purposes. See [Networking with QEMU User](#) for details.
- native\_posix board.
  - The Zephyr instance can be executed as a user space process in the host system. This is the most convenient way to debug the Zephyr system as one can attach host debugger directly to the running Zephyr instance. This requires that there is an adaptation driver in Zephyr for interfacing with the host system. An Ethernet driver exists in Zephyr for this purpose. See [Networking with native\\_posix board](#) for details.
- USB device networking.
  - Here, the Zephyr instance is run on a real board and the connectivity to the host system is done via USB. See [USB Device Networking](#) for details.
- Connecting multiple Zephyr instances together.
  - If you have multiple Zephyr instances, either QEMU or native\_posix ones, and want to create a connection between them, see [Networking with multiple Zephyr instances](#) for details.
- Simulating IEEE 802.15.4 network between two QEMUs.
  - Here, two Zephyr instances are running and there is IEEE 802.15.4 link layer run over an UART between them. See [Networking with QEMU and IEEE 802.15.4](#) for details.

### 8.14.5 Monitor Network Traffic

- [Host Configuration](#)
- [Zephyr Configuration](#)
- [Wireshark Configuration](#)

It is useful to be able to monitor the network traffic especially when debugging a connectivity issues or when developing new protocol support in Zephyr. This page describes how to set up a way to capture network traffic so that user is able to use Wireshark or similar tool in remote host to see the network packets sent or received by a Zephyr device.

See also the `net-capture-sample` sample application from the Zephyr source distribution for configuration options that need to be enabled.

#### Host Configuration

The instructions here describe how to setup a Linux host to capture Zephyr network RX and TX traffic. Similar instructions should work also in other operating systems. On the Linux Host, fetch the Zephyr `net-tools` project, which is located in a separate Git repository:

```
git clone https://github.com/zephyrproject-rtos/net-tools
```

The `net-tools` project provides a configure file to setup IP-to-IP tunnel interface so that we can transfer monitoring data from Zephyr to host.

In terminal #1, type:

```
./net-setup.sh -c zeth-tunnel.conf
```

This script will create following IPIP tunnel interfaces:

Interface name	Description
<code>zeth-ip6ip</code>	IPv6-over-IPv4 tunnel
<code>zeth-ipip</code>	IPv4-over-IPv4 tunnel
<code>zeth-ipip6</code>	IPv4-over-IPv6 tunnel
<code>zeth-ip6ip6</code>	IPv6-over-IPv6 tunnel

Zephyr will send captured network packets to one of these interfaces. The actual interface will depend on how the capturing is configured. You can then use Wireshark to monitor the proper network interface.

After the tunneling interfaces have been created, you can use for example `net-capture.py` script from `net-tools` project to print or save the captured network packets. The `net-capture.py` provides an UDP listener, it can print the captured data to screen and optionally can also save the data to a pcap file.

```
$ ./net-capture.py -i zeth-ip6ip -w capture.pcap
[20210408Z14:33:08.959589] Ether / IP / ICMP 192.0.2.1 > 192.0.2.2 echo-request 0 / 
↳Raw
[20210408Z14:33:08.976178] Ether / IP / ICMP 192.0.2.2 > 192.0.2.1 echo-reply 0 / Raw
[20210408Z14:33:16.176303] Ether / IPv6 / ICMPv6 Echo Request (id: 0x9feb seq: 0x0)
[20210408Z14:33:16.195326] Ether / IPv6 / ICMPv6 Echo Reply (id: 0x9feb seq: 0x0)
[20210408Z14:33:21.194979] Ether / IPv6 / ICMPv6ND_NS / ICMPv6 Neighbor Discovery
↳Option - Source Link-Layer Address 02:00:5e:00:53:3b
[20210408Z14:33:21.217528] Ether / IPv6 / ICMPv6ND_NA / ICMPv6 Neighbor Discovery
↳Option - Destination Link-Layer Address 00:00:5e:00:53:ff
```

(continues on next page)

(continued from previous page)

```
[20210408Z14:34:10.245408] Ether / IPv6 / UDP 2001:db8::2:47319 > 2001:db8::1:4242 /  
↪Raw  
[20210408Z14:34:10.266542] Ether / IPv6 / UDP 2001:db8::1:4242 > 2001:db8::2:47319 /  
↪Raw
```

The `net-capture.py` has following command line options:

```
Listen captured network data from Zephyr and save it optionally to pcap file.  
./net-capture.py \  
-i | --interface <network interface>  
    Listen this interface for the data  
[-p | --port <UDP port>]  
    UDP port (default is 4242) where the capture data is received  
[-q | --quiet]  
    Do not print packet information  
[-t | --type <L2 type of the data>]  
    Scapy L2 type name of the UDP payload, default is Ether  
[-w | --write <pcap file name>]  
    Write the received data to file in PCAP format
```

Instead of the `net-capture.py` script, you can for example use `netcat` to provide an UDP listener so that the host will not send port unreachable message to Zephyr:

```
nc -l -u 2001:db8:200::2 4242 > /dev/null
```

The IP address above is the inner tunnel endpoint, and can be changed and it depends on how the Zephyr is configured. Zephyr will send UDP packets containing the captured network packets to the configured IP tunnel, so we need to terminate the network connection like this.

## Zephyr Configuration

In this example, we use `native_posix` board. You can also use any other board that supports networking.

In terminal #3, type:

```
west build -b native_posix samples/net/capture -- -DCONFIG_NATIVE_UART_AUTOATTACH_  
↪DEFAULT_CMD="\\"gnome-terminal -- screen %s\\""
```

To see the Zephyr console and shell, start Zephyr instance like this:

```
build/zephyr/zephyr.exe -attach_uart
```

Any other application can be used too, just make sure that suitable configuration options are enabled (see `samples/net/capture/prj.conf` file for examples).

The network capture can be configured automatically if needed, but currently the capture sample application does not do that. User has to use `net-shell` to setup and enable the monitoring.

The network packet monitoring needs to be setup first. The `net-shell` has `net capture setup` command for doing that. The command syntax is

```
net capture setup <remote-ip-addr> <local-ip-addr> <peer-ip-addr>  
    <remote> is the (outer) endpoint IP address  
    <local> is the (inner) local IP address  
    <peer> is the (inner) peer IP address  
    Local and Peer IP addresses can have UDP port number in them (optional)  
    like 198.0.51.2:9000 or [2001:db8:100::2]:4242
```

In Zephyr console, type:

```
net capture setup 192.0.2.2 2001:db8:200::1 2001:db8:200::2
```

This command will create the tunneling interface. The 192.0.2.2 is the remote host where the tunnel is terminated. The address is used to select the local network interface where the tunneling interface is attached to. The 2001:db8:200::1 tells the local IP address for the tunnel, the 2001:db8:200::2 is the peer IP address where the captured network packets are sent. The port numbers for UDP packet can be given in the setup command like this for IPv6-over-IPv4 tunnel

```
net capture setup 192.0.2.2 [2001:db8:200::1]:9999 [2001:db8:200::2]:9998
```

and like this for IPv4-over-IPv4 tunnel

```
net capture setup 192.0.2.2 198.51.100.1:9999 198.51.100.2:9998
```

If the port number is omitted, then 4242 UDP port is used as a default.

The current monitoring configuration can be checked like this:

```
uart:~$ net capture
Network packet capture disabled
      Capture  Tunnel
Device      iface  iface  Local              Peer
NET_CAPTURE0 -      1      [2001:db8:200::1]:4242 [2001:db8:200::2]:4242
```

which will print the current configuration. As we have not yet enabled monitoring, the Capture iface is not set.

Then we need to enable the network packet monitoring like this:

```
net capture enable 2
```

The 2 tells the network interface which traffic we want to capture. In this example, the 2 is the native\_posix board Ethernet interface. Note that we send the network traffic to the same interface that we are monitoring in this example. The monitoring system avoids to capture already captured network traffic as that would lead to recursion. You can use net iface command to see what network interfaces are available. Note that you cannot capture traffic from the tunnel interface as that would cause recursion loop. The captured network traffic can be sent to some other network interface if configured so. Just set the <remote-ip-addr> option properly in net capture setup so that the IP tunnel is attached to desired network interface. The capture status can be checked again like this:

```
uart:~$ net capture
Network packet capture enabled
      Capture  Tunnel
Device      iface  iface  Local              Peer
NET_CAPTURE0 2      1      [2001:db8:200::1]:4242 [2001:db8:200::2]:4242
```

After enabling the monitoring, the system will send captured (either received or sent) network packets to the tunnel interface for further processing.

The monitoring can be disabled like this:

```
net capture disable
```

which will turn currently running monitoring off. The monitoring setup can be cleared like this:

```
net capture cleanup
```

It is not necessary to use net-shell for configuring the monitoring. The [network capture API](#) functions can be called by the application if needed.

## Wireshark Configuration

The [Wireshark](#) tool can be used to monitor the captured network traffic in a useful way.

You can monitor either the tunnel interfaces or the `zeth` interface. In order to see the actual captured data inside an UDP packet, see [Wireshark decapsulate UDP](#) document for instructions.

## 8.15 Using with PlatformIO

- [What is PlatformIO?](#)
- [Installation](#)

### 8.15.1 What is PlatformIO?

[PlatformIO](#) is a cross-platform embedded development environment with Zephyr support maintained by its developers.

Since Zephyr support within PlatformIO is not maintained by the Zephyr Project, please report any issues with PlatformIO directly to its developers in [the official PlatformIO repositories](#).

A detailed overview of the PlatformIO ecosystem and its philosophy can be found in [the official PlatformIO documentation](#).

### 8.15.2 Installation

- [PlatformIO IDE](#) is a toolset for embedded C/C++ development available on Windows, macOS and Linux platforms
- [PlatformIO Core \(CLI\)](#) is a command-line tool that consists of multi-platform build system, platform and library managers and other integration components. It can be used with a variety of code development environments and allows integration with cloud platforms and web services

### 8.15.3 Configuration

Please go through [the official PlatformIO configuration guide](#) for Zephyr project.

### 8.15.4 Tutorials

- Zephyr and Nordic nRF52-DK: debugging, unit testing, project analysis
- Developing Zephyr RTOS embedded applications on PlatformIO and simulating on Antmicro Renode

### 8.15.5 Project Examples

Please check [the official examples](#) for various development platforms

### 8.15.6 Next Steps

Here are some useful links for exploring the PlatformIO ecosystem:

- Try [other platforms](#) that support Zephyr project
- Learn more about [integrations with other IDEs/Text Editors](#)
- Get help from [PlatformIO community](#)

## 8.16 OS Abstraction

OS abstraction layers (OSAL) provide wrapper function APIs that encapsulate common system functions offered by any operating system. These APIs make it easier and quicker to develop for, and port code to multiple software and hardware platforms.

These sections describe the software and hardware abstraction layers supported by the Zephyr RTOS.

### 8.16.1 POSIX Support

The Portable Operating System Interface (POSIX) is a family of standards specified by the IEEE Computer Society for maintaining compatibility between operating systems. Zephyr implements a subset of the embedded profiles PSE51 and PSE52, and BSD Sockets API.

With the POSIX support available in Zephyr, an existing POSIX compliant application can be ported to run on the Zephyr kernel, and therefore leverage Zephyr features and functionality. Additionally, a library designed for use with POSIX threading compatible operating systems can be ported to Zephyr kernel based applications with minimal or no changes.

The POSIX API subset is an increasingly popular OSAL (operating system abstraction layer) for IoT and embedded applications, as can be seen in Zephyr, AWS:FreeRTOS, TI-RTOS, and NuttX.

Benefits of POSIX support in Zephyr include:

- Offering a familiar API to non-embedded programmers, especially from Linux
- Enabling reuse (portability) of existing libraries based on POSIX APIs
- Providing an efficient API subset appropriate for small (MCU) embedded systems

#### System Overview

**Units of Functionality** The system profile is defined in terms of component profiles that specify Units of Functionality that can be combined to realize the application platform. A Unit of Functionality is a defined set of services which can be implemented. If implemented, the standard prescribes that all services in the Unit must be implemented.

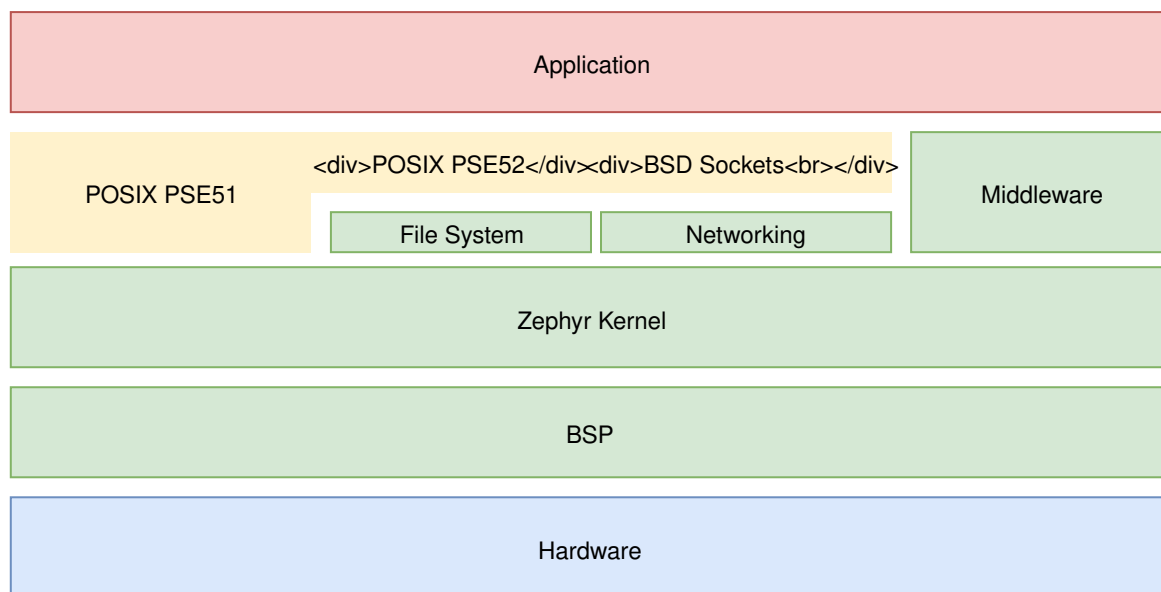

Fig. 11: POSIX support in Zephyr

A Minimal Realtime System Profile implementation must support the following Units of Functionality as defined in IEEE Std. 1003.1 (also referred to as POSIX.1-2017).

Table 7: Units of Functionality

Requirements	Supported	Remarks
POSIX_C_LANG_JUMP		
POSIX_C_LANG_SUPPORT	•	
POSIX_DEVICE_IO		
POSIX_FILE_LOCKING		
POSIX_SIGNALS		
POSIX_SINGLE_PROCESS		
POSIX_THREADS_BASE	•	
XSI_THREAD_MUTEX_EXT	•	
XSI_THREADS_EXT	•	

**Option Requirements** An implementation supporting the Minimal Realtime System Profile must support the POSIX.1 Option Requirements which are defined in the standard. Options Requirements are used for further sub-profiling within the units of functionality: they further define the functional behavior of the system service (normally adding extra functionality). Depending on the profile to which the POSIX implementation complies, parameters and/or the precise functionality of certain services may differ.

The following list shows the option requirements that are implemented in Zephyr.

Table 8: Option Requirements

Requirements	Supported
_POSIX_CLOCK_SELECTION	
_POSIX_FSYNC	
_POSIX_MEMLOCK	
_POSIX_MEMLOCK_RANGE	
_POSIX_MONOTONIC_CLOCK	
_POSIX_NO_TRUNC	
_POSIX_REALTIME_SIGNALS	
_POSIX_SEMAPHORES	•
_POSIX_SHARED_MEMORY_OBJECTS	
_POSIX_SYNCHRONIZED_IO	
_POSIX_THREAD_ATTR_STACKADDR	
_POSIX_THREAD_ATTR_STACKSIZE	
_POSIX_THREAD_CPUTIME	
_POSIX_THREAD_PRIO_INHERIT	•
_POSIX_THREAD_PRIO_PROTECT	
_POSIX_THREAD_PRIORITY_SCHEDULING	•
_POSIX_THREAD_SPORADIC_SERVER	
_POSIX_TIMEOUTS	
_POSIX_TIMERS	
_POSIX2_C_DEV	
_POSIX2_SW_DEV	

## Units of Functionality

This section describes the Units of Functionality (fixed sets of interfaces) which are implemented (partially or completely) in Zephyr. Please refer to the standard for a full description of each listed interface.

**POSIX\_THREADS\_BASE** The basic assumption in this profile is that the system consists of a single (implicit) process with multiple threads. Therefore, the standard requires all basic thread services, except those related to multiple processes.

Table 9: POSIX\_THREADS\_BASE

API	Supported
pthread_atfork()	
pthread_attr_destroy()	•
pthread_attr_getdetachstate()	•
pthread_attr_getschedparam()	•
pthread_attr_init()	•

continues on next page

Table 9 – continued from previous page

API	Supported

Table 9 – continued from previous page

API	Supported
<code>pthread_mutex_destroy()</code>	•
<code>pthread_mutex_init()</code>	•
<code>pthread_mutex_lock()</code>	•
<code>pthread_mutex_trylock()</code>	•
<code>pthread_mutex_unlock()</code>	•
<code>pthread_mutexattr_destroy()</code>	
<code>pthread_mutexattr_init()</code>	
<code>pthread_once()</code>	•
<code>pthread_self()</code>	•
<code>pthread_setcancelstate()</code>	
<code>pthread_setcanceltype()</code>	
<code>pthread_setspecific()</code>	•
<code>pthread_sigmask()</code>	
<code>pthread_testcancel()</code>	

**XSI\_THREAD\_EXT** The XSI\_THREADS\_EXT Unit of Functionality is required because it provides functions to control a thread's stack. This is considered useful for any real-time application.

This table lists service support status in Zephyr:

Table 10: XSI\_THREAD\_EXT

API	Supported
<code>pthread_attr_getguardsize()</code>	
<code>pthread_attr_getstack()</code>	•
<code>pthread_attr_setguardsize()</code>	
<code>pthread_attr_setstack()</code>	•
<code>pthread_getconcurrency()</code>	
<code>pthread_setconcurrency()</code>	

**XSI\_THREAD\_MUTEX\_EXT** The XSI\_THREAD\_MUTEX\_EXT Unit of Functionality is required because it has options for controlling the behavior of mutexes under erroneous application use.

This table lists service support status in Zephyr:

Table 11: XSI\_THREAD\_MUTEX\_EXT

API	Supported
pthread_mutexattr_gettype()	•
pthread_mutexattr_settype()	•

**POSIX\_C\_LANG\_SUPPORT** The POSIX\_C\_LANG\_SUPPORT Unit of Functionality contains the general ISO C Library.

This is implemented as part of the minimal C library available in Zephyr.

Table 12: POSIX\_C\_LANG\_SUPPORT

API	Supported

### 8.16.2 CMSIS RTOS v1

Cortex-M Software Interface Standard (CMSIS) RTOS is a vendor-independent hardware abstraction layer for the ARM Cortex-M processor series and defines generic tool interfaces. Though it was originally defined for ARM Cortex-M microcontrollers alone, it could be easily extended to other microcontrollers making it generic. For more information on CMSIS RTOS v1, please refer <http://www.keil.com/pack/doc/CMSIS/RTOS/html/index.html>

### 8.16.3 CMSIS RTOS v2

Cortex-M Software Interface Standard (CMSIS) RTOS is a vendor-independent hardware abstraction layer for the ARM Cortex-M processor series and defines generic tool interfaces. Though it was originally defined for ARM Cortex-M microcontrollers alone, it could be easily extended to other microcontrollers making it generic. For more information on CMSIS RTOS v2, please refer to the [CMSIS-RTOS2 Documentation](#).

#### Features not supported in Zephyr implementation

**Kernel** `osKernelGetState`, `osKernelSuspend`, `osKernelResume`, `osKernelInitialize` and `osKernelStart` are not supported.

**Mutex** `osMutexPrioInherit` is supported by default and is not configurable, you cannot select/unselect this attribute.

`osMutexRecursive` is also supported by default. If this attribute is not set, an error is thrown when the same thread tries to acquire it the second time.

`osMutexRobust` is not supported in Zephyr.

#### Return values not supported in the Zephyr implementation

`osKernelUnlock`, `osKernelLock`, `osKernelRestoreLock` `osError` (Unspecified error) is not supported.

`osSemaphoreDelete` `osErrorResource` (the semaphore specified by parameter `semaphore_id` is in an invalid semaphore state) is not supported.

`osMutexDelete` `osErrorResource` (mutex specified by parameter `mutex_id` is in an invalid mutex state) is not supported.

`osTimerDelete` `osErrorResource` (the timer specified by parameter `timer_id` is in an invalid timer state) is not supported.

`osMessageQueueReset osErrorResource` (the message queue specified by parameter `msgq_id` is in an invalid message queue state) is not supported.

`osMessageQueueDelete osErrorResource` (the message queue specified by parameter `msgq_id` is in an invalid message queue state) is not supported.

`osMemoryPoolFree osErrorResource` (the memory pool specified by parameter `mp_id` is in an invalid memory pool state) is not supported.

`osMemoryPoolDelete osErrorResource` (the memory pool specified by parameter `mp_id` is in an invalid memory pool state) is not supported.

`osEventFlagsSet, osEventFlagsClear osFlagsErrorUnknown` (Unspecified error) and `osFlagsErrorResource` (Event flags object specified by parameter `ef_id` is not ready to be used) are not supported.

`osEventFlagsDelete osErrorParameter` (the value of the parameter `ef_id` is incorrect) is not supported.

`osThreadFlagsSet osFlagsErrorUnknown` (Unspecified error) and `osFlagsErrorResource` (Thread specified by parameter `thread_id` is not active to receive flags) are not supported.

`osThreadFlagsClear osFlagsErrorResource` (Running thread is not active to receive flags) is not supported.

`osDelayUntil osParameter` (the time cannot be handled) is not supported.

## 8.17 Porting

These pages document how to port Zephyr to new hardware.

### 8.17.1 Architecture Porting Guide

An architecture port is needed to enable Zephyr to run on an ISA (instruction set architecture) or an ABI (Application Binary Interface) that is not currently supported.

The following are examples of ISAs and ABIs that Zephyr supports:

- x86\_32 ISA with System V ABI
- ARMv7-M ISA with Thumb2 instruction set and ARM Embedded ABI (aeabi)
- ARCoV2 ISA

For information on Kconfig configuration, see [Setting Kconfig configuration values](#). Architectures use a Kconfig configuration scheme similar to boards.

An architecture port can be divided in several parts; most are required and some are optional:

- **The early boot sequence:** each architecture has different steps it must take when the CPU comes out of reset (required).
- **Interrupt and exception handling:** each architecture handles asynchronous and unrequested events in a specific manner (required).
- **Thread context switching:** the Zephyr context switch is dependent on the ABI and each ISA has a different set of registers to save (required).
- **Thread creation and termination:** A thread's initial stack frame is ABI and architecture-dependent, and thread abortion possibly as well (required).
- **Device drivers:** most often, the system clock timer and the interrupt controller are tied to the architecture (some required, some optional).
- **Utility libraries:** some common kernel APIs rely on a architecture-specific implementation for performance reasons (required).

- **CPU idling/power management:** most architectures implement instructions for putting the CPU to sleep (partly optional, most likely very desired).
- **Fault management:** for implementing architecture-specific debug help and handling of fatal error in threads (partly optional).
- **Linker scripts and toolchains:** architecture-specific details will most likely be needed in the build system and when linking the image (required).

## Early Boot Sequence

The goal of the early boot sequence is to take the system from the state it is after reset to a state where it can run C code and thus the common kernel initialization sequence. Most of the time, very few steps are needed, while some architectures require a bit more work to be performed.

Common steps for all architectures:

- Setup an initial stack.
- If running an XIP (eXecute-In-Place) kernel, copy initialized data
  - from ROM to RAM.
- If not using an ELF loader, zero the BSS section.
- Jump to `_Cstart()`, the early kernel initialization
  - `_Cstart()` is responsible for context switching out of the fake context running at startup into the main thread.

Some examples of architecture-specific steps that have to be taken:

- If given control in real mode on x86\_32, switch to 32-bit protected mode.
- Setup the segment registers on x86\_32 to handle boot loaders that leave them in an unknown or broken state.
- Initialize a board-specific watchdog on Cortex-M3/4.
- Switch stacks from MSP to PSP on Cortex-M.
- Use a different approach than calling into `_Swap()` on Cortex-M to prevent race conditions.
- Setup FIRQ and regular IRQ handling on ARCv2.

## Interrupt and Exception Handling

Each architecture defines interrupt and exception handling differently.

When a device wants to signal the processor that there is some work to be done on its behalf, it raises an interrupt. When a thread does an operation that is not handled by the serial flow of the software itself, it raises an exception. Both, interrupts and exceptions, pass control to a handler. The handler is known as an ISR (Interrupt Service Routine) in the case of interrupts. The handler performs the work required by the exception or the interrupt. For interrupts, that work is device-specific. For exceptions, it depends on the exception, but most often the core kernel itself is responsible for providing the handler.

The kernel has to perform some work in addition to the work the handler itself performs. For example:

- Prior to handing control to the handler:
  - Save the currently executing context.
  - Possibly getting out of power saving mode, which includes waking up devices.
  - Updating the kernel uptime if getting out of tickless idle mode.
- After getting control back from the handler:

- Decide whether to perform a context switch.
- When performing a context switch, restore the context being context switched in.

This work is conceptually the same across architectures, but the details are completely different:

- The registers to save and restore.
- The processor instructions to perform the work.
- The numbering of the exceptions.
- etc.

It thus needs an architecture-specific implementation, called the interrupt/exception stub.

Another issue is that the kernel defines the signature of ISRs as:

```
void (*isr)(void *parameter)
```

Architectures do not have a consistent or native way of handling parameters to an ISR. As such there are two commonly used methods for handling the parameter.

- Using some architecture defined mechanism, the parameter value is forced in the stub. This is commonly found in X86-based architectures.
- The parameters to the ISR are inserted and tracked via a separate table requiring the architecture to discover at runtime which interrupt is executing. A common interrupt handler demuxer is installed for all entries of the real interrupt vector table, which then fetches the device's ISR and parameter from the separate table. This approach is commonly used in the ARC and ARM architectures via the `:kconfig: CONFIG_GEN_ISR_TABLES` implementation. You can find examples of the stubs by looking at `_interrupt_enter()` in x86, `_IntExit()` in ARM, `_isr_wrapper()` in ARM, or the full implementation description for ARC in `arch/arc/core/isr_wrapper.S`.

Each architecture also has to implement primitives for interrupt control:

- locking interrupts: `irq_lock()`, `irq_unlock()`.
- registering interrupts: `IRQ_CONNECT()`.
- programming the priority if possible `irq_priority_set()`.
- enabling/disabling interrupts: `irq_enable()`, `irq_disable()`.

---

**Note:** `IRQ_CONNECT` is a macro that uses assembler and/or linker script tricks to connect interrupts at build time, saving boot time and text size.

---

The vector table should contain a handler for each interrupt and exception that can possibly occur. The handler can be as simple as a spinning loop. However, we strongly suggest that handlers at least print some debug information. The information helps figuring out what went wrong when hitting an exception that is a fault, like divide-by-zero or invalid memory access, or an interrupt that is not expected (*spurious interrupt*). See the ARM implementation in `arch/arm/core/aarch32/cortex_m/fault.c` for an example.

## Thread Context Switching

Multi-threading is the basic purpose to have a kernel at all. Zephyr supports two types of threads: preemptible and cooperative.

Two crucial concepts when writing an architecture port are the following:

- Cooperative threads run at a higher priority than preemptible ones, and always preempt them.
- After handling an interrupt, if a cooperative thread was interrupted, the kernel always goes back to running that thread, since it is not preemptible.

A context switch can happen in several circumstances:

- When a thread executes a blocking operation, such as taking a semaphore that is currently unavailable.
- When a preemptible thread unblocks a thread of higher priority by releasing the object on which it was blocked.
- When an interrupt unblocks a thread of higher priority than the one currently executing, if the currently executing thread is preemptible.
- When a thread runs to completion.
- When a thread causes a fatal exception and is removed from the running threads. For example, referencing invalid memory,

Therefore, the context switching must thus be able to handle all these cases.

The kernel keeps the next thread to run in a “cache”, and thus the context switching code only has to fetch from that cache to select which thread to run.

There are two types of context switches: *cooperative* and *preemptive*.

- A *cooperative* context switch happens when a thread willfully gives the control to another thread. There are two cases where this happens
  - When a thread explicitly yields.
  - When a thread tries to take an object that is currently unavailable and is willing to wait until the object becomes available.
- A *preemptive* context switch happens either because an ISR or a thread causes an operation that schedules a thread of higher priority than the one currently running, if the currently running thread is preemptible. An example of such an operation is releasing an object on which the thread of higher priority was waiting.

---

**Note:** Control is never taken from cooperative thread when one of them is the running thread.

---

A cooperative context switch is always done by having a thread call the `_Swap()` kernel internal symbol. When `_Swap` is called, the kernel logic knows that a context switch has to happen: `_Swap` does not check to see if a context switch must happen. Rather, `_Swap` decides what thread to context switch in. `_Swap` is called by the kernel logic when an object being operated on is unavailable, and some thread yielding/sleeping primitives.

---

**Note:** On x86 and Nios2, `_Swap` is generic enough and the architecture flexible enough that `_Swap` can be called when exiting an interrupt to provoke the context switch. This should not be taken as a rule, since neither the ARM Cortex-M or ARCV2 port do this.

---

Since `_Swap` is cooperative, the caller-saved registers from the ABI are already on the stack. There is no need to save them in the `k_thread` structure.

A context switch can also be performed preemptively. This happens upon exiting an ISR, in the kernel interrupt exit stub:

- `_interrupt_enter` on x86 after the handler is called.
- `_IntExit` on ARM.
- `_firq_exit` and `_rirq_exit` on ARCV2.

In this case, the context switch must only be invoked when the interrupted thread was preemptible, not when it was a cooperative one, and only when the current interrupt is not nested.

The kernel also has the concept of “locking the scheduler”. This is a concept similar to locking the interrupts, but lighter-weight since interrupts can still occur. If a thread has locked the scheduler, it is temporarily non-preemptible.

So, the decision logic to invoke the context switch when exiting an interrupt is simple:

- If the interrupted thread is not preemptible, do not invoke it.
- Else, fetch the cached thread from the ready queue, and:
  - If the cached thread is not the current thread, invoke the context switch.
  - Else, do not invoke it.

This is simple, but crucial: if this is not implemented correctly, the kernel will not function as intended and will experience bizarre crashes, mostly due to stack corruption.

---

**Note:** If running a coop-only system, i.e. if `:kconfig: `CONFIG_NUM_PREEMPT_PRIORITIES`` is 0, no preemptive context switch ever happens. The interrupt code can be optimized to not take any scheduling decision when this is the case.

---

## Thread Creation and Termination

To start a new thread, a stack frame must be constructed so that the context switch can pop it the same way it would pop one from a thread that had been context switched out. This is to be implemented in an architecture-specific `_new_thread` internal routine.

The thread entry point is also not to be called directly, i.e. it should not be set as the PC (program counter) for the new thread. Rather it must be wrapped in `_thread_entry`. This means that the PC in the stack frame shall be set to `_thread_entry`, and the thread entry point shall be passed as the first parameter to `_thread_entry`. The specifics of this depend on the ABI.

The need for an architecture-specific thread termination implementation depends on the architecture. There is a generic implementation, but it might not work for a given architecture.

One reason that has been encountered for having an architecture-specific implementation of thread termination is that aborting a thread might be different if aborting because of a graceful exit or because of an exception. This is the case for ARM Cortex-M, where the CPU has to be taken out of handler mode if the thread triggered a fatal exception, but not if the thread gracefully exits its entry point function.

This means implementing an architecture-specific version of `k_thread_abort()`, and setting the Kconfig option `:kconfig: `CONFIG_ARCH_HAS_THREAD_ABORT`` as needed for the architecture (e.g. see [arch/arm/core/aarch32/cortex\\_m/Kconfig](#)).

## Thread Local Storage

To enable thread local storage on a new architecture:

1. Implement `arch_tls_stack_setup()` to setup the TLS storage area in stack. Refer to the toolchain documentation on how the storage area needs to be structured. Some helper functions can be used:
  - Function `z_tls_data_size()` returns the size needed for thread local variables (excluding any extra data required by toolchain and architecture).
  - Function `z_tls_copy()` prepares the TLS storage area for thread local variables. This only copies the variable themselves and does not do architecture and/or toolchain specific data.
2. In the context switching, grab the `tls` field inside the new thread's `struct k_thread` and put it into an appropriate register (or some other variable) for access to the TLS storage area. Refer to toolchain and architecture documentation on which registers to use.
3. In kconfig, add `select CONFIG_ARCH_HAS_THREAD_LOCAL_STORAGE` to kconfig related to the new architecture.
4. Run the `tests/kernel/threads/tls` to make sure the new code works.

## Device Drivers

The kernel requires very few hardware devices to function. In theory, the only required device is the interrupt controller, since the kernel can run without a system clock. In practice, to get access to most, if not all, of the sanity check test suite, a system clock is needed as well. Since these two are usually tied to the architecture, they are part of the architecture port.

**Interrupt Controllers** There can be significant differences between the interrupt controllers and the interrupt concepts across architectures.

For example, x86 has the concept of an IDT and different interrupt controllers. The position of an interrupt in the IDT determines its priority.

On the other hand, the ARM Cortex-M has the NVIC (Nested Vectored Interrupt Controller) as part of the architecture definition. There is no need for an IDT-like table that is separate from the NVIC vector table. The position in the table has nothing to do with priority of an IRQ: priorities are programmable per-entry.

The ARChv2 has its interrupt unit as part of the architecture definition, which is somewhat similar to the NVIC. However, where ARC defines interrupts as having a one-to-one mapping between exception and interrupt numbers (i.e. exception 1 is IRQ1, and device IRQs start at 16), ARM has IRQ0 being equivalent to exception 16 (and weirdly enough, exception 1 can be seen as IRQ-15).

All these differences mean that very little, if anything, can be shared between architectures with regards to interrupt controllers.

**System Clock** x86 has APIC timers and the HPET as part of its architecture definition. ARM Cortex-M has the SYSTICK exception. Finally, ARChv2 has the timer0/1 device.

Kernel timeouts are handled in the context of the system clock timer driver's interrupt handler.

**Console Over Serial Line** There is one other device that is almost a requirement for an architecture port, since it is so useful for debugging. It is a simple polling, output-only, serial port driver on which to send the console (`printf`, `putc`) output.

It is not required, and a RAM console (`:kconfig: CONFIG_RAM_CONSOLE`) can be used to send all output to a circular buffer that can be read by a debugger instead.

## Utility Libraries

The kernel depends on a few functions that can be implemented with very few instructions or in a lock-less manner in modern processors. Those are thus expected to be implemented as part of an architecture port.

- Atomic operators.
  - If instructions do exist for a given architecture, the implementation is configured using the `:kconfig: CONFIG_ATOMIC_OPERATIONS_ARCH` Kconfig option.
  - If instructions do not exist for a given architecture, a generic version that wraps `irq_lock()` or `irq_unlock()` around non-atomic operations exists. It is configured using the `:kconfig: CONFIG_ATOMIC_OPERATIONS_C` Kconfig option.
- Find-least-significant-bit-set and find-most-significant-bit-set.
  - If instructions do not exist for a given architecture, it is always possible to implement these functions as generic C functions.

It is possible to use compiler built-ins to implement these, but be careful they use the required compiler barriers.

## CPU Idling/Power Management

The kernel provides support for CPU power management with two functions: `arch_cpu_idle()` and `arch_cpu_atomic_idle()`.

`arch_cpu_idle()` can be as simple as calling the power saving instruction for the architecture with interrupts unlocked, for example `hlt` on x86, `wfi` or `wfe` on ARM, `sleep` on ARC. This function can be called in a loop within a context that does not care if it get interrupted or not by an interrupt before going to sleep. There are basically two scenarios when it is correct to use this function:

- In a single-threaded system, in the only thread when the thread is not used for doing real work after initialization, i.e. it is sitting in a loop doing nothing for the duration of the application.
- In the idle thread.

`arch_cpu_atomic_idle()`, on the other hand, must be able to atomically re-enable interrupts and invoke the power saving instruction. It can thus be used in real application code, again in single-threaded systems.

Normally, idling the CPU should be left to the idle thread, but in some very special scenarios, these APIs can be used by applications.

Both functions must exist for a given architecture. However, the implementation can be simply the following steps, if desired:

1. unlock interrupts
2. NOP

However, a real implementation is strongly recommended.

## Fault Management

In the event of an unhandled CPU exception, the architecture code must call into `z_fatal_error()`. This function dumps out architecture-agnostic information and makes a policy decision on what to do next by invoking `k_sys_fatal_error()`. This function can be overridden to implement application-specific policies that could include locking interrupts and spinning forever (the default implementation) or even powering off the system (if supported).

## Toolchain and Linking

Toolchain support has to be added to the build system.

Some architecture-specific definitions are needed in `include/toolchain/gcc.h`. See what exists in that file for currently supported architectures.

Each architecture also needs its own linker script, even if most sections can be derived from the linker scripts of other architectures. Some sections might be specific to the new architecture, for example the SCB section on ARM and the IDT section on x86.

## Memory Management

If the target platform enables paging and requires drivers to memory-map their I/O regions, `CONFIG_MMU` needs to be enabled and the `arch_mem_map()` API implemented.

## Stack Objects

The presence of memory protection hardware affects how stack objects are created. All architecture ports must specify the required alignment of the stack pointer, which is some combination of CPU and

ABI requirements. This is defined in architecture headers with `ARCH_STACK_PTR_ALIGN` and is typically something small like 4, 8, or 16 bytes.

Two types of thread stacks exist:

- “kernel” stacks defined with `K_KERNEL_STACK_DEFINE()` and related APIs, which can host kernel threads running in supervisor mode or used as the stack for interrupt/exception handling. These have significantly relaxed alignment requirements and use less reserved data. No memory is reserved for privilege elevation stacks.
- “thread” stacks which typically use more memory, but are capable of hosting thread running in user mode, as well as any use-cases for kernel stacks.

If `:c:kconfig:CONFIG_USERSPACE` is not enabled, “thread” and “kernel” stacks are equivalent.

Additional macros may be defined in the architecture layer to specify the alignment of the base of stack objects, any reserved data inside the stack object not used for the thread’s stack buffer, and how to round up stack sizes to support user mode threads. In the absence of definitions some defaults are assumed:

- `ARCH_KERNEL_STACK_RESERVED`: default no reserved space
- `ARCH_THREAD_STACK_RESERVED`: default no reserved space
- `ARCH_KERNEL_STACK_OBJ_ALIGN`: default align to `ARCH_STACK_PTR_ALIGN`
- `ARCH_THREAD_STACK_OBJ_ALIGN`: default align to `ARCH_STACK_PTR_ALIGN`
- `ARCH_THREAD_STACK_SIZE_ALIGN`: default round up to `ARCH_STACK_PTR_ALIGN`

All stack creation macros are defined in terms of these.

Stack objects all have the following layout, with some regions potentially zero-sized depending on configuration. There are always two main parts: reserved memory at the beginning, and then the stack buffer itself. The bounds of some areas can only be determined at runtime in the context of its associated thread object. Other areas are entirely computable at build time.

Some architectures may need to carve-out reserved memory at runtime from the stack buffer, instead of unconditionally reserving it at build time, or to supplement an existing reserved area (as is the case with the ARM FPU). Such carve-outs will always be tracked in `thread.stack_info.start`. The region specified by `thread.stack_info.start` and `thread.stack_info.size` is always fully accessible by a user mode thread. `thread.stack_info.delta` denotes an offset which can be used to compute the initial stack pointer from the very end of the stack object, taking into account storage for TLS and ASLR random offsets.

```
+-----+ <- thread.stack_obj
| Reserved Memory | } K_(THREAD|KERNEL)_STACK_RESERVED
+-----+
| Carved-out memory |
| ..... | <- thread.stack_info.start
| Unused stack buffer |
| ..... | <- thread's current stack pointer
| Used stack buffer |
| ..... | <- Initial stack pointer. Computable
| ASLR Random offset | with thread.stack_info.delta
+-----+ <- thread.userspace_local_data
| Thread-local data |
+-----+ <- thread.stack_info.start +
| ..... | thread.stack_info.size
```

At present, Zephyr does not support stacks that grow upward.

**No Memory Protection** If no memory protection is in use, then the defaults are sufficient.

**HW-based stack overflow detection** This option uses hardware features to generate a fatal error if a thread in supervisor mode overflows its stack. This is useful for debugging, although for a couple reasons, you can't reliably make any assertions about the state of the system after this happens:

- The kernel could have been inside a critical section when the overflow occurs, leaving important global data structures in a corrupted state.
- For systems that implement stack protection using a guard memory region, it's possible to overshoot the guard and corrupt adjacent data structures before the hardware detects this situation.

To enable the `:kconfig: `CONFIG_HW_STACK_PROTECTION`` feature, the system must provide some kind of hardware-based stack overflow protection, and enable the `:kconfig: `CONFIG_ARCH_HAS_STACK_PROTECTION`` option.

Two forms of HW-based stack overflow detection are supported: dedicated CPU features for this purpose, or special read-only guard regions immediately preceding stack buffers.

`:kconfig: `CONFIG_HW_STACK_PROTECTION`` only catches stack overflows for supervisor threads. This is not required to catch stack overflow from user threads; `:kconfig: `CONFIG_USERSPACE`` is orthogonal.

This feature only detects supervisor mode stack overflows, including stack overflows when handling system calls. It doesn't guarantee that the kernel has not been corrupted. Any stack overflow in supervisor mode should be treated as a fatal error, with no assertions about the integrity of the overall system possible.

Stack overflows in user mode are recoverable (from the kernel's perspective) and require no special configuration; `:kconfig: `CONFIG_HW_STACK_PROTECTION`` only applies to catching overflows when the CPU is in supervisor mode.

**CPU-based stack overflow detection** If we are detecting stack overflows in supervisor mode via special CPU registers (like ARM's SPLIM), then the defaults are sufficient.

**Guard-based stack overflow detection** We are detecting supervisor mode stack overflows via special memory protection region located immediately before the stack buffer that generates an exception on write. Reserved memory will be used for the guard region.

`ARCH_KERNEL_STACK_RESERVED` should be defined to the minimum size of a memory protection region. On most ARM CPUs this is 32 bytes. `ARCH_KERNEL_STACK_OBJ_ALIGN` should also be set to the required alignment for this region.

MMU-based systems should not reserve RAM for the guard region and instead simply leave a non-present virtual page below every stack when it is mapped into the address space. The stack object will still need to be properly aligned and sized to page granularity.

```
+-----+ <- thread.stack_obj
| Guard reserved memory | } K_KERNEL_STACK_RESERVED
+-----+
| Guard carve-out       |
| .....                | <- thread.stack_info.start
| Stack buffer          |
|                       |
```

Guard carve-outs for kernel stacks are uncommon and should be avoided if possible. They tend to be needed for two situations:

- The same stack may be re-purposed to host a user thread, in which case the guard is unnecessary and shouldn't be unconditionally reserved. This is the case when privilege elevation stacks are not inside the stack object.
- The required guard size is variable and depends on context. For example, some ARM CPUs have lazy floating point stacking during exceptions and may decrement the stack pointer by a large

value without writing anything, completely overshooting a minimally-sized guard and corrupting adjacent memory. Rather than unconditionally reserving a larger guard, the extra memory is carved out if the thread uses floating point.

**User mode enabled** Enabling user mode activates two new requirements:

- A separate fixed-sized privilege mode stack, specified by **:kconfig: `CONFIG\_PRIVILEGED\_STACK\_SIZE`**, must be allocated that the user thread cannot access. It is used as the stack by the kernel when handling system calls. If stack guards are implemented, a stack guard region must be able to be placed before it, with support for carve-outs if necessary.
- The memory protection hardware must be able to program a region that exactly covers the thread's stack buffer, tracked in `thread.stack_info`. This implies that `ARCH_THREAD_STACK_SIZE_ADJUST()` will need to round up the requested stack size so that a region may cover it, and that `ARCH_THREAD_STACK_OBJ_ALIGN()` is also specified per the granularity of the memory protection hardware.

This becomes more complicated if the memory protection hardware requires that all memory regions be sized to a power of two, and aligned to their own size. This is common on older MPUs and is known with **:kconfig: `CONFIG\_MPU\_REQUIRES\_POWER\_OF\_TWO\_ALIGNMENT`**.

`thread.stack_info` always tracks the user-accessible part of the stack object, it must always be correct to program a memory protection region with user access using the range stored within.

**Non power-of-two memory region requirements** On systems without power-of-two region requirements, the reserved memory area for threads stacks defined by `K_THREAD_STACK_RESERVED` may be used to contain the privilege mode stack. The layout could be something like:

```
+-----+ <- thread.stack_obj
| Other platform data |
+-----+
| Guard region (if enabled) |
+-----+
| Guard carve-out (if needed) |
| ..... |
| Privilege elevation stack |
+-----+ <- thread.stack_obj +
| Stack buffer | K_THREAD_STACK_RESERVED =
| . | thread.stack_info.start
```

The guard region, and any carve-out (if needed) would be configured as a read-only region when the thread is created.

- If the thread is a supervisor thread, the privilege elevation region is just extra stack memory. An overflow will eventually crash into the guard region.
- If the thread is running in user mode, a memory protection region will be configured to allow user threads access to the stack buffer, but nothing before or after it. An overflow in user mode will crash into the privilege elevation stack, which the user thread has no access to. An overflow when handling a system call will crash into the guard region.

On an MMU system there should be no physical guards; the privilege mode stack will be mapped into kernel memory, and the stack buffer in the user part of memory, each with non-present virtual guard pages below them to catch runtime stack overflows.

Other platform data may be stored before the guard region, but this is highly discouraged if such data could be stored in `thread.arch` somewhere.

`ARCH_THREAD_STACK_RESERVED` will need to be defined to capture the size of the reserved region containing platform data, privilege elevation stacks, and guards. It must be appropriately sized such that an

MPU region to grant user mode access to the stack buffer can be placed immediately after it.

**Power-of-two memory region requirements** Thread stack objects must be sized and aligned to the same power of two, without any reserved memory to allow efficient packing in memory. Thus, any guards in the thread stack must be completely carved out, and the privilege elevation stack must be allocated elsewhere.

`ARCH_THREAD_STACK_SIZE_ADJUST()` and `ARCH_THREAD_STACK_OBJ_ALIGN()` should both be defined to `Z_POW2_CEIL()`. `K_THREAD_STACK_RESERVED` must be 0.

For the privilege stacks, the **:kconfig: `CONFIG\_GEN\_PRIV\_STACKS`** must be enabled. For every thread stack found in the system, a corresponding fixed-size kernel stack used for handling system calls is generated. The address of the privilege stacks can be looked up quickly at runtime based on the thread stack address using `z_priv_stack_find()`. These stacks are laid out the same way as other kernel-only stacks.

```
+-----+ <- z_priv_stack_find(thread.stack_obj)
| Reserved memory          | } K_KERNEL_STACK_RESERVED
+-----+
| Guard carve-out (if needed) |
| .....                   |
| Privilege elevation stack  |
| .....                   |
+-----+ <- z_priv_stack_find(thread.stack_obj) +
                                     K_KERNEL_STACK_RESERVED +
                                     CONFIG_PRIVILEGED_STACK_SIZE

+-----+ <- thread.stack_obj
| MPU guard carve-out      |
| (supervisor mode only)   |
| .....                   | <- thread.stack_info.start
| Stack buffer             |
| .....                   |
+-----+
```

The guard carve-out in the thread stack object is only used if the thread is running in supervisor mode. If the thread drops to user mode, there is no guard and the entire object is used as the stack buffer, with full access to the associated user mode thread and `thread.stack_info` updated appropriately.

## User Mode Threads

To support user mode threads, several kernel-to-arch APIs need to be implemented, and the system must enable the **:kconfig: `CONFIG\_ARCH\_HAS\_USERSPACE`** option. Please see the documentation for each of these functions for more details:

- `arch_buffer_validate()` to test whether the current thread has access permissions to a particular memory region
- `arch_user_mode_enter()` which will irreversibly drop a supervisor thread to user mode privileges. The stack must be wiped.
- `arch_syscall_oops()` which generates a kernel oops when system call parameters can't be validated, in such a way that the oops appears to be generated from where the system call was invoked in the user thread
- `arch_syscall_invoke0()` through `arch_syscall_invoke6()` invoke a system call with the appropriate number of arguments which must all be passed in during the privilege elevation via registers.
- `arch_is_user_context()` return nonzero if the CPU is currently running in user mode

- `arch_mem_domain_max_partitions_get()` which indicates the max number of regions for a memory domain. MMU systems have an unlimited amount, MPU systems have constraints on this.

Some architectures may need to update software memory management structures or modify hardware registers on another CPU when memory domain APIs are invoked. If so, **:kconfig: `CONFIG\_ARCH\_MEM\_DOMAIN\_SYNCHRONOUS\_API`** must be selected by the architecture and some additional APIs must be implemented. This is common on MMU systems and uncommon on MPU systems:

- `arch_mem_domain_thread_add()`
- `arch_mem_domain_thread_remove()`
- `arch_mem_domain_partition_add()`
- `arch_mem_domain_partition_remove()`

Please see the doxygen documentation of these APIs for details.

In addition to implementing these APIs, there are some other tasks as well:

- `_new_thread()` needs to spawn threads with `K_USER` in user mode
- On context switch, the outgoing thread's stack memory should be marked inaccessible to user mode by making the appropriate configuration changes in the memory management hardware.. The incoming thread's stack memory should likewise be marked as accessible. This ensures that threads can't mess with other thread stacks.
- On context switch, the system needs to switch between memory domains for the incoming and outgoing threads.
- Thread stack areas must include a kernel stack region. This should be inaccessible to user threads at all times. This stack will be used when system calls are made. This should be fixed size for all threads, and must be large enough to handle any system call.
- A software interrupt or some kind of privilege elevation mechanism needs to be established. This is closely tied to how the `_arch_syscall_invoke` macros are implemented. On system call, the appropriate handler function needs to be looked up in `_k_syscall_table`. Bad system call IDs should jump to the `K_SYSCALL_BAD` handler. Upon completion of the system call, care must be taken not to leak any register state back to user mode.

## API Reference

### Timing

*group arch-timing*

#### Unnamed Group

`void arch_timing_init(void)`

Initialize the timing subsystem.

Perform the necessary steps to initialize the timing subsystem.

**See also:**

[`timing\_init\(\)`](#)

`void arch_timing_start(void)`

Signal the start of the timing information gathering.

Signal to the timing subsystem that timing information will be gathered from this point forward.

**See also:**

[\*timing\\_start\(\)\*](#)

`void arch_timing_stop(void)`

Signal the end of the timing information gathering.

Signal to the timing subsystem that timing information is no longer being gathered from this point forward.

**See also:**

[\*timing\\_stop\(\)\*](#)

`timing_t arch_timing_counter_get(void)`

Return timing counter.

**See also:**

[\*timing\\_counter\\_get\(\)\*](#)

**Returns** Timing counter.

`uint64_t arch_timing_cycles_get(volatile timing_t *const start, volatile timing_t *const end)`

Get number of cycles between start and end.

For some architectures or SoCs, the raw numbers from counter need to be scaled to obtain actual number of cycles.

**See also:**

[\*timing\\_cycles\\_get\(\)\*](#)

**Parameters**

- `start` – Pointer to counter at start of a measured execution.
- `end` – Pointer to counter at stop of a measured execution.

**Returns** Number of cycles between start and end.

`uint64_t arch_timing_freq_get(void)`

Get frequency of counter used (in Hz).

**See also:**

[\*timing\\_freq\\_get\(\)\*](#)

**Returns** Frequency of counter used for timing in Hz.

`uint64_t arch_timing_cycles_to_ns(uint64_t cycles)`

Convert number of cycles into nanoseconds.

**See also:**

[\*timing\\_cycles\\_to\\_ns\(\)\*](#)

**Parameters**

- `cycles` – Number of cycles

**Returns** Converted time value

`uint64_t arch_timing_cycles_to_ns_avg(uint64_t cycles, uint32_t count)`

Convert number of cycles into nanoseconds with averaging.

**See also:**

[\*timing\\_cycles\\_to\\_ns\\_avg\(\)\*](#)

**Parameters**

- `cycles` – Number of cycles
- `count` – Times of accumulated cycles to average over

**Returns** Converted time value

`uint32_t arch_timing_freq_get_mhz(void)`

Get frequency of counter used (in MHz).

**See also:**

[\*timing\\_freq\\_get\\_mhz\(\)\*](#)

**Returns** Frequency of counter used for timing in MHz.

**Functions**

`void arch_busy_wait(uint32_t usec_to_wait)`

Architecture-specific implementation of busy-waiting

**Parameters**

- `usec_to_wait` – Wait period, in microseconds

`static inline uint32_t arch_k_cycle_get_32(void)`

Obtain the current cycle count, in units that are hardware-specific

**See also:**

[\*k\\_cycle\\_get\\_32\(\)\*](#)

**Threads**

*group* `arch-threads`

**Functions**

```
void arch_new_thread(struct k_thread *thread, k_thread_stack_t *stack, char *stack_ptr,
                    k_thread_entry_t entry, void *p1, void *p2, void *p3)
```

Handle arch-specific logic for setting up new threads

The stack and arch-specific thread state variables must be set up such that a later attempt to switch to this thread will succeed and we will enter `z_thread_entry` with the requested thread and arguments as its parameters.

At some point in this function's implementation, `z_setup_new_thread()` must be called with the true bounds of the available stack buffer within the thread's stack object.

The provided stack pointer is guaranteed to be properly aligned with respect to the CPU and ABI requirements. There may be space reserved between the stack pointer and the bounds of the stack buffer for initial stack pointer randomization and thread-local storage.

Fields in `thread->base` will be initialized when this is called.

#### Parameters

- `thread` – Pointer to uninitialized struct `k_thread`
- `stack` – Pointer to the stack object
- `stack_ptr` – Aligned initial stack pointer
- `entry` – Thread entry function
- `p1` – 1st entry point parameter
- `p2` – 2nd entry point parameter
- `p3` – 3rd entry point parameter

```
static inline void arch_switch(void *switch_to, void **switched_from)
```

Cooperative context switch primitive

The action of `arch_switch()` should be to switch to a new context passed in the first argument, and save a pointer to the current context into the address passed in the second argument.

The actual type and interpretation of the switch handle is specified by the architecture. It is the same data structure stored in the “switch\_handle” field of a newly-created thread in `arch_new_thread()`, and passed to the kernel as the “interrupted” argument to `z_get_next_switch_handle()`.

Note that on SMP systems, the kernel uses the store through the second pointer as a synchronization point to detect when a thread context is completely saved (so another CPU can know when it is safe to switch). This store must be done AFTER all relevant state is saved, and must include whatever memory barriers or cache management code is required to be sure another CPU will see the result correctly.

The simplest implementation of `arch_switch()` is generally to push state onto the thread stack and use the resulting stack pointer as the switch handle. Some architectures may instead decide to use a pointer into the thread struct as the “switch handle” type. These can legally assume that the second argument to `arch_switch()` is the address of the `switch_handle` field of struct `thread_base` and can use an offset on this value to find other parts of the thread struct. For example a (C pseudocode) implementation of `arch_switch()` might look like:

```
void arch_switch(void *switch_to, void **switched_from) { struct k_thread *new = switch_to;
struct k_thread *old = CONTAINER_OF(switched_from, struct k_thread, switch_handle);
// save old context... *switched_from = old; // restore new context... }
```

Note that the kernel manages the `switch_handle` field for synchronization as described above. So it is not legal for architecture code to assume that it has any particular value at any other time. In particular it is not legal to read the field from the address passed in the second argument.

#### Parameters

- `switch_to` – Incoming thread’s switch handle
- `switched_from` – Pointer to outgoing thread’s switch handle storage location, which must be updated.

```
void arch_switch_to_main_thread(struct k_thread *main_thread, char *stack_ptr,  
                                k_thread_entry_t _main)
```

Custom logic for entering main thread context at early boot

Used by architectures where the typical trick of setting up a dummy thread in early boot context to “switch out” of isn’t workable.

#### Parameters

- `main_thread` – main thread object
- `stack_ptr` – Initial stack pointer
- `_main` – Entry point for application main function.

```
int arch_float_disable(struct k_thread *thread)
```

Disable floating point context preservation.

The function is used to disable the preservation of floating point context information for a particular thread.

---

**Note:** For ARM architecture, disabling floating point preservation may only be requested for the current thread and cannot be requested in ISRs.

---

#### Return values

- 0 – On success.
- `-EINVAL` – If the floating point disabling could not be performed.
- `-ENOTSUP` – If the operation is not supported

```
int arch_float_enable(struct k_thread *thread, unsigned int options)
```

Enable floating point context preservation.

The function is used to enable the preservation of floating point context information for a particular thread. This API depends on each architecture implementation. If the architecture does not support enabling, this API will always be failed.

The *options* parameter indicates which floating point register sets will be used by the specified thread. Currently it is used by x86 only.

#### Parameters

- `thread` – ID of thread.
- `options` – architecture dependent options

#### Return values

- 0 – On success.
- `-EINVAL` – If the floating point enabling could not be performed.
- `-ENOTSUP` – If the operation is not supported

*group arch-tls*

## Functions

size\_t arch\_tls\_stack\_setup(struct [k\\_thread](#) \*new\_thread, char \*stack\_ptr)

Setup Architecture-specific TLS area in stack.

This sets up the stack area for thread local storage. The structure inside in area is architecture specific.

### Parameters

- new\_thread – New thread object
- stack\_ptr – Stack pointer

**Returns** Number of bytes taken by the TLS area

## Power Management

group arch-pm

## Functions

FUNC\_NORETURN void arch\_system\_halt(unsigned int reason)

Halt the system, optionally propagating a reason code

void arch\_cpu\_idle(void)

Power save idle routine.

This function will be called by the kernel idle loop or possibly within an implementation of `z_pm_save_idle` in the kernel when the ‘\_pm\_save\_flag’ variable is non-zero.

Architectures that do not implement power management instructions may immediately return, otherwise a power-saving instruction should be issued to wait for an interrupt.

### See also:

[k\\_cpu\\_idle\(\)](#)

---

**Note:** The function is expected to return after the interrupt that has caused the CPU to exit power-saving mode has been serviced, although this is not a firm requirement.

---

void arch\_cpu\_atomic\_idle(unsigned int key)

Atomically re-enable interrupts and enter low power mode.

The requirements for [arch\\_cpu\\_atomic\\_idle\(\)](#) are as follows:

- Enabling interrupts and entering a low-power mode needs to be atomic, i.e. there should be no period of time where interrupts are enabled before the processor enters a low-power mode. See the comments in [k\\_lifo\\_get\(\)](#), for example, of the race condition that occurs if this requirement is not met.
- After waking up from the low-power mode, the interrupt lockout state must be restored as indicated in the ‘key’ input parameter.

### See also:

[k\\_cpu\\_atomic\\_idle\(\)](#)

### Parameters

- `key` – Lockout key returned by previous invocation of [arch\\_irq\\_lock\(\)](#)

## Symmetric Multi-Processing

group arch-smp

### Typedefs

```
typedef FUNC_NORETURN void (*arch_cpustart_t)(void *data)
```

Per-cpu entry function

**Param data** context parameter, implementation specific

### Functions

```
void arch_start_cpu(int cpu_num, k_thread_stack_t *stack, int sz, arch_cpustart_t fn, void *arg)
```

Start a numbered CPU on a MP-capable system.

This starts and initializes a specific CPU. The main thread on startup is running on CPU zero, other processors are numbered sequentially. On return from this function, the CPU is known to have begun operating and will enter the provided function. Its interrupts will be initialized but disabled such that [irq\\_unlock\(\)](#) with the provided key will work to enable them.

Normally, in SMP mode this function will be called by the kernel initialization and should not be used as a user API. But it is defined here for special-purpose apps which want Zephyr running on one core and to use others for design-specific processing.

### Parameters

- `cpu_num` – Integer number of the CPU
- `stack` – Stack memory for the CPU
- `sz` – Stack buffer size, in bytes
- `fn` – Function to begin running on the CPU.
- `arg` – Untyped argument to be passed to “fn”

```
bool arch_cpu_active(int cpu_num)
```

Return CPU power status.

### Parameters

- `cpu_num` – Integer number of the CPU

```
static inline struct _cpu *arch_curr_cpu(void)
```

Return the CPU struct for the currently executing CPU

```
void arch_sched_ipi(void)
```

Broadcast an interrupt to all CPUs

This will invoke `z_sched_ipi()` on other CPUs in the system.

## Interrupts

group arch-irq

## Functions

static inline bool arch\_is\_in\_isr(void)

Test if the current context is in interrupt context

XXX: This is inconsistently handled among arches wrt exception context See: #17656

**Returns** true if we are in interrupt context

static inline unsigned int arch\_irq\_lock(void)

Lock interrupts on the current CPU

**See also:**

[\*irq\\_lock\(\)\*](#)

static inline void arch\_irq\_unlock(unsigned int key)

Unlock interrupts on the current CPU

**See also:**

[\*irq\\_unlock\(\)\*](#)

static inline bool arch\_irq\_unlocked(unsigned int key)

Test if calling [\*arch\\_irq\\_unlock\(\)\*](#) with this key would unlock irqs

### Parameters

- key – value returned by [\*arch\\_irq\\_lock\(\)\*](#)

**Returns** true if interrupts were unlocked prior to the [\*arch\\_irq\\_lock\(\)\*](#) call that produced the key argument.

void arch\_irq\_disable(unsigned int irq)

Disable the specified interrupt line

**See also:**

[\*irq\\_disable\(\)\*](#)

---

**Note:** : The behavior of interrupts that arrive after this call returns and before the corresponding call to [\*arch\\_irq\\_enable\(\)\*](#) is undefined. The hardware is not required to latch and deliver such an interrupt, though on some architectures that may work. Other architectures will simply lose such an interrupt and never deliver it. Many drivers and subsystems are not tolerant of such dropped interrupts and it is the job of the application layer to ensure that behavior remains correct.

---

void arch\_irq\_enable(unsigned int irq)

Enable the specified interrupt line

**See also:**

[\*irq\\_enable\(\)\*](#)

```
int arch_irq_is_enabled(unsigned int irq)
    Test if an interrupt line is enabled
```

**See also:**

[\*irq\\_is\\_enabled\(\)\*](#)

```
int arch_irq_connect_dynamic(unsigned int irq, unsigned int priority, void (*routine)(const
    void *parameter), const void *parameter, uint32_t flags)
```

Arch-specific hook to install a dynamic interrupt.

**Parameters**

- `irq` – IRQ line number
- `priority` – Interrupt priority
- `routine` – Interrupt service routine
- `parameter` – ISR parameter
- `flags` – Arch-specific IRQ configuration flag

**Returns** The vector assigned to this interrupt

## Userspace

*group* arch-userspace

## Functions

```
static inline uintptr_t arch_syscall_invoke0(uintptr_t call_id)
```

Invoke a system call with 0 arguments.

No general-purpose register state other than return value may be preserved when transitioning from supervisor mode back down to user mode for security reasons.

It is required that all arguments be stored in registers when elevating privileges from user to supervisor mode.

Processing of the syscall takes place on a separate kernel stack. Interrupts should be enabled when invoking the system call marshallers from the dispatch table. Thread preemption may occur when handling system calls.

Call ids are untrusted and must be bounds-checked, as the value is used to index the system call dispatch table, containing function pointers to the specific system call code.

**Parameters**

- `call_id` – System call ID

**Returns** Return value of the system call. Void system calls return 0 here.

```
static inline uintptr_t arch_syscall_invoke1(uintptr_t arg1, uintptr_t call_id)
```

Invoke a system call with 1 argument.

**See also:**

[\*arch\\_syscall\\_invoke0\(\)\*](#)

**Parameters**

- `arg1` – First argument to the system call.

- `call_id` – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

**Returns** Return value of the system call. Void system calls return 0 here.

```
static inline uintptr_t arch_syscall_invoke2(uintptr_t arg1, uintptr_t arg2, uintptr_t call_id)
```

Invoke a system call with 2 arguments.

**See also:**

[\*arch\\_syscall\\_invoke0\(\)\*](#)

**Parameters**

- `arg1` – First argument to the system call.
- `arg2` – Second argument to the system call.
- `call_id` – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

**Returns** Return value of the system call. Void system calls return 0 here.

```
static inline uintptr_t arch_syscall_invoke3(uintptr_t arg1, uintptr_t arg2, uintptr_t arg3,  
                                             uintptr_t call_id)
```

Invoke a system call with 3 arguments.

**See also:**

[\*arch\\_syscall\\_invoke0\(\)\*](#)

**Parameters**

- `arg1` – First argument to the system call.
- `arg2` – Second argument to the system call.
- `arg3` – Third argument to the system call.
- `call_id` – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

**Returns** Return value of the system call. Void system calls return 0 here.

```
static inline uintptr_t arch_syscall_invoke4(uintptr_t arg1, uintptr_t arg2, uintptr_t arg3,  
                                             uintptr_t arg4, uintptr_t call_id)
```

Invoke a system call with 4 arguments.

**See also:**

[\*arch\\_syscall\\_invoke0\(\)\*](#)

**Parameters**

- `arg1` – First argument to the system call.
- `arg2` – Second argument to the system call.
- `arg3` – Third argument to the system call.
- `arg4` – Fourth argument to the system call.

- `call_id` – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

**Returns** Return value of the system call. Void system calls return 0 here.

```
static inline uintptr_t arch_syscall_invoke5(uintptr_t arg1, uintptr_t arg2, uintptr_t arg3,
                                             uintptr_t arg4, uintptr_t arg5, uintptr_t call_id)
```

Invoke a system call with 5 arguments.

**See also:**

[\*arch\\_syscall\\_invoke0\(\)\*](#)

#### Parameters

- `arg1` – First argument to the system call.
- `arg2` – Second argument to the system call.
- `arg3` – Third argument to the system call.
- `arg4` – Fourth argument to the system call.
- `arg5` – Fifth argument to the system call.
- `call_id` – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

**Returns** Return value of the system call. Void system calls return 0 here.

```
static inline uintptr_t arch_syscall_invoke6(uintptr_t arg1, uintptr_t arg2, uintptr_t arg3,
                                             uintptr_t arg4, uintptr_t arg5, uintptr_t arg6,
                                             uintptr_t call_id)
```

Invoke a system call with 6 arguments.

**See also:**

[\*arch\\_syscall\\_invoke0\(\)\*](#)

#### Parameters

- `arg1` – First argument to the system call.
- `arg2` – Second argument to the system call.
- `arg3` – Third argument to the system call.
- `arg4` – Fourth argument to the system call.
- `arg5` – Fifth argument to the system call.
- `arg6` – Sixth argument to the system call.
- `call_id` – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

**Returns** Return value of the system call. Void system calls return 0 here.

```
static inline bool arch_is_user_context(void)
```

Indicate whether we are currently running in user mode

**Returns** true if the CPU is currently running with user permissions

```
int arch_mem_domain_max_partitions_get(void)
```

Get the maximum number of partitions for a memory domain.

**Returns** Max number of partitions, or -1 if there is no limit

```
int arch_buffer_validate(void *addr, size_t size, int write)
```

Check memory region permissions.

Given a memory region, return whether the current memory management hardware configuration would allow a user thread to read/write that region. Used by system calls to validate buffers coming in from userspace.

Notes: The function is guaranteed to never return validation success, if the entire buffer area is not user accessible.

The function is guaranteed to correctly validate the permissions of the supplied buffer, if the user access permissions of the entire buffer are enforced by a single, enabled memory management region.

In some architectures the validation will always return failure if the supplied memory buffer spans multiple enabled memory management regions (even if all such regions permit user access).

**Warning:** 0 size buffer has undefined behavior.

#### Parameters

- `addr` – start address of the buffer
- `size` – the size of the buffer
- `write` – If nonzero, additionally check if the area is writable. Otherwise, just check if the memory can be read.

**Returns** nonzero if the permissions don't match.

```
FUNC_NORETURN void arch_user_mode_enter(k_thread_entry_t user_entry, void *p1, void *p2, void *p3)
```

Perform a one-way transition from supervisor to kernel mode.

Implementations of this function must do the following:

- Reset the thread's stack pointer to a suitable initial value. We do not need any prior context since this is a one-way operation.
- Set up any kernel stack region for the CPU to use during privilege elevation
- Put the CPU in whatever its equivalent of user mode is
- Transfer execution to [arch\\_new\\_thread\(\)](#) passing along all the supplied arguments, in user mode.

#### Parameters

- `user_entry` – Entry point to start executing as a user thread
- `p1` – 1st parameter to user thread
- `p2` – 2nd parameter to user thread
- `p3` – 3rd parameter to user thread

`FUNC_NORETURN void arch_syscall_oops(void *ssf)`

Induce a kernel oops that appears to come from a specific location.

Normally, `k_oops()` generates an exception that appears to come from the call site of the `k_oops()` itself.

However, when validating arguments to a system call, if there are problems we want the oops to appear to come from where the system call was invoked and not inside the validation function.

#### Parameters

- `ssf` – System call stack frame pointer. This gets passed as an argument to `_k_syscall_handler_t` functions and its contents are completely architecture specific.

`size_t arch_user_string_nlen(const char *s, size_t maxsize, int *err)`

Safely take the length of a potentially bad string.

This must not fault, instead the `err` parameter must have -1 written to it. This function otherwise should work exactly like `libc strlen()`. On success `*err` should be set to 0.

#### Parameters

- `s` – String to measure
- `maxsize` – Max length of the string
- `err` – Error value to write

**Returns** Length of the string, not counting NULL byte, up to `maxsize`

`static inline bool arch_mem_coherent(void *ptr)`

Detect memory coherence type.

Required when `ARCH_HAS_COHERENCE` is true. This function returns true if the byte pointed to lies within an architecture-defined “coherence region” (typically implemented with uncached memory) and can safely be used in multiprocessor code without explicit flush or invalidate operations.

---

**Note:** The result is for only the single byte at the specified address, this API is not required to check region boundaries or to expect aligned pointers. The expectation is that the code above will have queried the appropriate address(es).

---

`static inline void arch_cohere_stacks(struct k\_thread *old_thread, void *old_switch_handle, struct k\_thread *new_thread)`

Ensure cache coherence prior to context switch.

Required when `ARCH_HAS_COHERENCE` is true. On cache-incoherent multiprocessor architectures, thread stacks are cached by default for performance reasons. They must therefore be flushed appropriately on context switch. The rules are:

- a. The region containing live data in the old stack (generally the bytes between the current stack pointer and the top of the stack memory) must be flushed to underlying storage so a new CPU that runs the same thread sees the correct data. This must happen before the assignment of the `switch_handle` field in the thread struct which signals the completion of context switch.
- b. Any data areas to be read from the new stack (generally the same as the live region when it was saved) should be invalidated (and NOT flushed!) in the data cache. This is because another CPU may have run or re-initialized the thread since this CPU suspended it, and any data present in cache will be stale.

- `old_thread` The old thread to be flushed before being allowed to run on other CPUs.
- `old_switch_handle` The switch handle to be stored into `old_thread` (it will not be valid until the cache is flushed so is not present yet). This will be NULL if inside `z_swap()` (because the `arch_switch()` has not saved it yet).
- `new_thread` The new thread to be invalidated before it runs locally.

---

**Note:** The kernel will call this function during interrupt exit when a new thread has been chosen to run, and also immediately before entering `arch_switch()` to effect a code-driven context switch. In the latter case, it is very likely that more data will be written to the `old_thread` stack region after this function returns but before the completion of the switch. Simply flushing naively here is not sufficient on many architectures and coordination with the `arch_switch()` implementation is likely required.

---

## Memory Management

group arch-mmio

### Functions

void `arch_mem_map`(void \*virt, uintptr\_t phys, size\_t size, uint32\_t flags)

Map physical memory into the virtual address space

This is a low-level interface to mapping pages into the address space. Behavior when providing unaligned addresses/sizes is undefined, these are assumed to be aligned to `CONFIG_MMU_PAGE_SIZE`.

The core kernel handles all management of the virtual address space; by the time we invoke this function, we know exactly where this mapping will be established. If the page tables already had mappings installed for the virtual memory region, these will be overwritten.

If the target architecture supports multiple page sizes, currently only the smallest page size will be used.

The memory range itself is never accessed by this operation.

This API must be safe to call in ISRs or exception handlers. Calls to this API are assumed to be serialized, and indeed all usage will originate from `kernel/mm.c` which handles virtual memory management.

Architectures are expected to pre-allocate page tables for the entire address space, as defined by `CONFIG_KERNEL_VM_BASE` and `CONFIG_KERNEL_VM_SIZE`. This operation should never require any kind of allocation for paging structures.

Validation of arguments should be done via assertions.

This API is part of infrastructure still under development and may change.

#### Parameters

- `virt` – Page-aligned Destination virtual address to map
- `phys` – Page-aligned Source physical address to map
- `size` – Page-aligned size of the mapped memory region in bytes
- `flags` – Caching, access and control flags, see `K_MAP_*` macros

```
void arch_mem_unmap(void *addr, size_t size)
```

Remove mappings for a provided virtual address range

This is a low-level interface for un-mapping pages from the address space. When this completes, the relevant page table entries will be updated as if no mapping was ever made for that memory range. No previous context needs to be preserved. This function must update mappings in all active page tables.

Behavior when providing unaligned addresses/sizes is undefined, these are assumed to be aligned to CONFIG\_MMU\_PAGE\_SIZE.

Behavior when providing an address range that is not already mapped is undefined.

This function should never require memory allocations for paging structures, and it is not necessary to free any paging structures. Empty page tables due to all contained entries being un-mapped may remain in place.

Implementations must invalidate TLBs as necessary.

This API is part of infrastructure still under development and may change.

#### Parameters

- `addr` – Page-aligned base virtual address to un-map
- `size` – Page-aligned region size

```
int arch_page_phys_get(void *virt, uintptr_t *phys)
```

Get the mapped physical memory address from virtual address.

The function only needs to query the current set of page tables as the information it reports must be common to all of them if multiple page tables are in use. If multiple page tables are active it is unnecessary to iterate over all of them.

Unless otherwise specified, virtual pages have the same mappings across all page tables. Calling this function on data pages that are exceptions to this rule (such as the scratch page) is undefined behavior. Just check the currently installed page tables and return the information in that.

#### Parameters

- `virt` – Page-aligned virtual address
- `phys` – **[out]** Mapped physical address (can be NULL if only checking if virtual address is mapped)

#### Return values

- 0 – if mapping is found and valid
- -EFAULT – if virtual address is not mapped

## Miscellaneous Architecture APIs

*group arch-misc*

### Functions

```
int arch_printk_char_out(int c)
```

Early boot console output hook

Definition of this function is optional. If implemented, any invocation of `printk()` (or logging calls with `CONFIG_LOG_MINIMAL` which are backed by `printk`) will default to sending characters to this function. It is useful for early boot debugging before main serial or console drivers come up.

This can be overridden at runtime with `__printk_hook_install()`.

The default `__weak` implementation of this does nothing.

#### Parameters

- `c` – Character to print

**Returns** The character printed

```
static inline void arch_kernel_init(void)
```

Architecture-specific kernel initialization hook

This function is invoked near the top of `_Cstart`, for additional architecture-specific setup before the rest of the kernel is brought up.

TODO: Deprecate, most arches are using a `prep_c()` function to do the same thing in a simpler way

```
static inline void arch_nop(void)
```

Do nothing and return. Yawn.

## 8.17.2 Board Porting Guide

To add Zephyr support for a new board, you at least need a *board directory* with various files in it. Files in the board directory inherit support for at least one SoC and all of its features. Therefore, Zephyr must support your SoC as well.

### Boards, SoCs, etc.

Zephyr's hardware support hierarchy has these layers, from most to least specific:

- Board: a particular CPU instance and its peripherals in a concrete hardware specification
- SoC: the exact system on a chip the board's CPU is part of
- SoC series: a smaller group of tightly related SoCs
- SoC family: a wider group of SoCs with similar characteristics
- CPU core: a particular CPU in an architecture
- Architecture: an instruction set architecture

You can visualize the hierarchy like this:

Here are some examples. Notice how the SoC series and family levels are not always used.

Board	SoC	SoC series	SoC family	CPU core		Architec- ture
nrf52dk_nrf52832	nRF52832	nRF52	Nordic nRF5	Arm	Cortex-M4	Arm
frdm_k64f	MK64F12	Kinetis K6x	NXP Kinetis	Arm	Cortex-M4	Arm
stm32h747i_disco	STM32H747XI	STM32H7	STMicro STM32	Arm	Cortex-M7	Arm
rv32m1_vega_riscy	RV32M1	(Not used)	(Not used)	RISCY		RISC-V

### Make sure your SoC is supported

Start by making sure your SoC is supported by Zephyr. If it is, it's time to [Create your board directory](#). If you don't know, try:

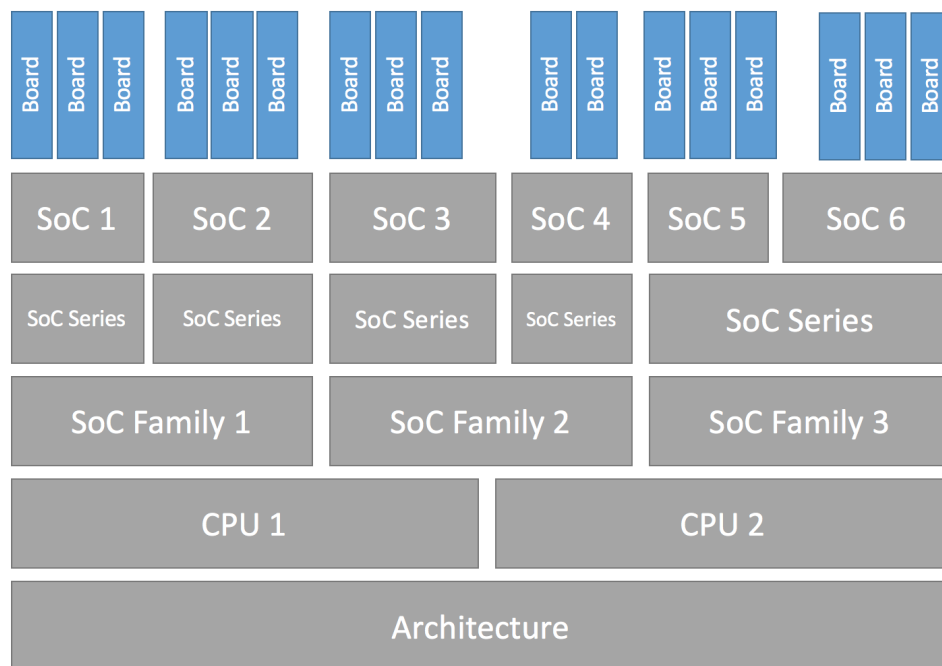

Fig. 12: Configuration Hierarchy

- checking boards for names that look relevant, and reading individual board documentation to find out for sure.
- asking your SoC vendor

If you need to add SoC, CPU core, or even architecture support, this is the wrong page, but here is some general advice.

**Architecture** See [Architecture Porting Guide](#).

**CPU Core** CPU core support files go in `core` subdirectories under `arch`, e.g. `arch/x86/core`.

See [Set Up a Toolchain](#) for information about toolchains (compiler, linker, etc.) supported by Zephyr. If you need to support a new toolchain, [Build and Configuration Systems](#) is a good place to start learning about the build system. Please reach out to the community if you are looking for advice or want to collaborate on toolchain support.

**SoC** Zephyr SoC support files are in architecture-specific subdirectories of `soc`. They are generally grouped by SoC family.

When adding a new SoC family or series for a vendor that already has SoC support within Zephyr, please try to extract common functionality into shared files to avoid duplication. If there is no support for your vendor yet, you can add it in a new directory `zephyr/soc/<YOUR-ARCH>/<YOUR-SOC>`; please use self-explanatory directory names.

### Create your board directory

Once you've found an existing board that uses your SoC, you can usually start by copy/pasting its board directory and changing its contents for your hardware.

You need to give your board a unique name. Run `west boards` for a list of names that are already taken, and pick something new. Let's say your board is called `plank` (please don't actually use that name).

Start by creating the board directory `zephyr/boards/<ARCH>/plank`, where `<ARCH>` is your SoC's architecture subdirectory. (You don't have to put your board directory in the zephyr repository, but it's the easiest way to get started. See [Custom Board, Devicetree and SOC Definitions](#) for documentation on moving your board directory to a separate repository once it's working.)

Your board directory should look like this:

```
boards/<ARCH>/plank
├── board.cmake
├── CMakeLists.txt
├── doc
│   ├── plank.png
│   └── index.rst
├── Kconfig.board
├── Kconfig.defconfig
├── plank_defconfig
├── plank.dts
└── plank.yaml
```

Replace `plank` with your board's name, of course.

The mandatory files are:

1. `plank.dts`: a hardware description in [devicetree](#) format. This declares your SoC, connectors, and any other hardware components such as LEDs, buttons, sensors, or communication peripherals (USB, BLE controller, etc).
2. `Kconfig.board`, `Kconfig.defconfig`, `plank_defconfig`: software configuration in [Configuration System \(Kconfig\)](#) formats. This provides default settings for software features and peripheral drivers.

The optional files are:

- `board.cmake`: used for [Flash and debug support](#)
- `CMakeLists.txt`: if you need to add additional source files to your build.

One common use for this file is to add a `pinmux.c` file in your board directory to the build, which configures pin controllers at boot time. In that case, `CMakeLists.txt` usually looks like this:

```
if(CONFIG_PINMUX)
    zephyr_library()
    zephyr_library_sources(pinmux.c)
endif()
```

- `doc/index.rst`, `doc/plank.png`: documentation for and a picture of your board. You only need this if you're [Contributing your board](#) to Zephyr.
- `plank.yaml`: a YAML file with miscellaneous metadata used by the [Test Runner \(Twister\)](#).

## Write your devicetree

The devicetree file `boards/<ARCH>/plank/plank.dts` describes your board hardware in the Devicetree Source (DTS) format (as usual, change `plank` to your board's name). If you're new to devicetree, see [Introduction to devicetree](#).

In general, `plank.dts` should look like this:

```
/dts-v1/;
#include <your_soc_vendor/your_soc.dtsi>

/ {
    model = "A human readable name";
    compatible = "yourcompany,plank";

    chosen {
        zephyr,console = &your_uart_console;
        zephyr,sram = &your_memory_node;
        /* other chosen settings for your hardware */
    };

    /*
     * Your board-specific hardware: buttons, LEDs, sensors, etc.
     */

    leds {
        compatible = "gpio-leds";
        led0: led_0 {
            gpios = < /* GPIO your LED is hooked up to */ >;
            label = "LED 0";
        };
        /* ... other LEDs ... */
    };

    buttons {
        compatible = "gpio-keys";
        /* ... your button definitions ... */
    };

    /* These aliases are provided for compatibility with samples */
    aliases {
        led0 = &led0; /* now you support the blinky sample! */
        /* other aliases go here */
    };
};

&some_peripheral_you_want_to_enable { /* like a GPIO or SPI controller */
    status = "okay";
};

&another_peripheral_you_want {
    status = "okay";
};
```

If you're in a hurry, simple hardware can usually be supported by copy/paste followed by trial and error. If you want to understand details, you will need to read the rest of the devicetree documentation and the devicetree specification.

**Example: FRDM-K64F and Hexiwear K64** This section contains concrete examples related to writing your board's devicetree.

The FRDM-K64F and Hexiwear K64 board devicetrees are defined in `frdm_k64fs.dts` and `hexiwear_k64.dts` respectively. Both boards have NXP SoCs from the same Kinetis SoC family, the K6X.

Common devicetree definitions for K6X are stored in `npx_k6x.dtsi`, which is included by both board `.dts` files. `npx_k6x.dtsi` in turn includes `armv7-m.dtsi`, which has common definitions for Arm v7-M cores.

Since `nxp_k6x.dtsi` is meant to be generic across K6X-based boards, it leaves many devices disabled by default using status properties. For example, there is a CAN controller defined as follows (with unimportant parts skipped):

```
can0: can@40024000 {
    ...
    status = "disabled";
    ...
};
```

It is up to the board `.dts` or application overlay files to enable these devices as desired, by setting `status = "okay"`. The board `.dts` files are also responsible for any board-specific configuration of the device, such as adding nodes for on-board sensors, LEDs, buttons, etc.

For example, FRDM-K64 (but not Hexiwear K64) `.dts` enables the CAN controller and sets the bus speed:

```
&can0 {
    status = "okay";
    bus-speed = <125000>;
};
```

The `&can0 { ... }` syntax adds/overrides properties on the node with label `can0`, i.e. the `can@40024000` node defined in the `.dtsi` file.

Other examples of board-specific customization is pointing properties in aliases and chosen to the right nodes (see [Aliases and chosen nodes](#)), and making GPIO/pinmux assignments.

## Write Kconfig files

Zephyr uses the Kconfig language to configure software features. Your board needs to provide some Kconfig settings before you can compile a Zephyr application for it.

Setting Kconfig configuration values is documented in detail in [Setting Kconfig configuration values](#).

There are three mandatory Kconfig files in the board directory for a board named `plank`:

```
boards/<ARCH>/plank
├─ Kconfig.board
├─ Kconfig.defconfig
└─ plank_defconfig
```

`Kconfig.board` Included by `boards/Kconfig` to include your board in the list of options.

This should at least contain a definition for a `BOARD_PLANK` option, which looks something like this:

```
config BOARD_PLANK
    bool "Plank board"
    depends on SOC_SERIES_YOUR_SOC_SERIES_HERE
    select SOC_PART_NUMBER_ABCDEFGH
```

`Kconfig.defconfig` Board-specific default values for Kconfig options.

The entire file should be inside an `if BOARD_PLANK / endif` pair of lines, like this:

```
if BOARD_PLANK

# Always set CONFIG_BOARD here. This isn't meant to be customized,
# but is set as a "default" due to Kconfig language restrictions.
config BOARD
    default "plank"
```

(continues on next page)

(continued from previous page)

```
# Other options you want enabled by default go next. Examples:

config FOO
    default y

if NETWORKING
config SOC_ETHERNET_DRIVER
    default y
endif # NETWORKING

endif # BOARD_PLANK
```

`plank_defconfig` A Kconfig fragment that is merged as-is into the final build directory `.config` whenever an application is compiled for your board.

You should at least select your board's SOC and do any mandatory settings for your system clock, console, etc. The results are architecture-specific, but typically look something like this:

```
CONFIG_SOC_${VENDOR_XYZ3000}=y          /* select your SoC */
CONFIG_SYS_CLOCK_HW_CYCLES_PER_SEC=120000000 /* set up your clock, etc */
CONFIG_SERIAL=y
```

`plank_x_y_z.conf` A Kconfig fragment that is merged as-is into the final build directory `.config` whenever an application is compiled for your board revision `x.y.z`.

## Build, test, and fix

Now it's time to build and test the application(s) you want to run on your board until you're satisfied.

For example:

```
west build -b plank samples/hello_world
west flash
```

For `west flash` to work, see [Flash and debug support](#) below. You can also just flash `build/zephyr/zephyr.elf`, `zephyr.hex`, or `zephyr.bin` with any other tools you prefer.

## General recommendations

For consistency and to make it easier for users to build generic applications that are not board specific for your board, please follow these guidelines while porting.

- Unless explicitly recommended otherwise by this section, leave peripherals and their drivers disabled by default.
- Configure and enable a system clock, along with a tick source.
- Provide pin and driver configuration that matches the board's valuable components such as sensors, buttons or LEDs, and communication interfaces such as USB, Ethernet connector, or Bluetooth/Wi-Fi chip.
- If your board uses a well-known connector standard (like Arduino, Mikrobús, Grove, or 96Boards connectors), add connector nodes to your DTS and configure pin muxes accordingly.
- Configure components that enable the use of these pins, such as configuring an SPI instance to use the usual Arduino SPI pins.
- If available, configure and enable a serial output for the console using the `zephyr,console` chosen node in the devicetree.

- If your board supports networking, configure a default interface.
- Enable all GPIO ports connected to peripherals or expansion connectors.
- If available, enable pinmux and interrupt controller drivers.
- It is recommended to enable the MPU by default, if there is support for it in hardware. For boards with limited memory resources it is acceptable to disable it. When the MPU is enabled, it is recommended to also enable hardware stack protection (`CONFIG_HW_STACK_PROTECTION=y`) and, thus, allow the kernel to detect stack overflows when the system is running in privileged mode.

## Flash and debug support

Zephyr supports *Building, Flashing and Debugging* via west extension commands.

To add west `flash` and west `debug` support for your board, you need to create a `board.cmake` file in your board directory. This file's job is to configure a “runner” for your board. (There's nothing special you need to do to get west `build` support for your board.)

“Runners” are Zephyr-specific Python classes that wrap *flash and debug host tools* and integrate with west and the zephyr build system to support west `flash` and related commands. Each runner supports flashing, debugging, or both. You need to configure the arguments to these Python scripts in your `board.cmake` to support those commands like this example `board.cmake`:

```
board_runner_args(jlink "--device=nrf52" "--speed=4000")
board_runner_args(pyocd "--target=nrf52" "--frequency=4000000")

include(${ZEPHYR_BASE}/boards/common/nrfjprog.board.cmake)
include(${ZEPHYR_BASE}/boards/common/jlink.board.cmake)
include(${ZEPHYR_BASE}/boards/common/pyocd.board.cmake)
```

This example configures the `nrfjprog`, `jlink`, and `pyocd` runners.

**Warning:** Runners usually have names which match the tools they wrap, so the `jlink` runner wraps Segger's J-Link tools, and so on. But the runner command line options like `--speed` etc. are specific to the Python scripts.

For more details:

- Run `west flash --context` to see a list of available runners which support flashing, and `west flash --context -r <RUNNER>` to view the specific options available for an individual runner.
- Run `west debug --context` and `west debug --context <RUNNER>` to get the same output for runners which support debugging.
- Run `west flash --help` and `west debug --help` for top-level options for flashing and debugging.
- See *Flash and debug runners* for Python APIs.
- Look for `board.cmake` files for other boards similar to your own for more examples.

To see what a west `flash` or west `debug` command is doing exactly, run it in verbose mode:

```
west --verbose flash
west --verbose debug
```

Verbose mode prints any host tool commands the runner uses.

The order of the `include()` calls in your `board.cmake` matters. The first `include` sets the default runner if it's not already set. For example, including `nrfjprog.board.cmake` first means that `nrfjprog` is the default flash runner for this board. Since `nrfjprog` does not support debugging, `jlink` is the default debug runner.

## Multiple board revisions

See [Building for a board revision](#) for basics on this feature from the user perspective.

To create a new board revision for the plank board, create these additional files in the board folder:

```
boards/<ARCH>/plank
├─ plank_<revision>.conf      # optional
├─ plank_<revision>.overlay  # optional
└─ revision.cmake
```

When the user builds for board `plank@<revision>`:

- The optional Kconfig settings specified in the file `plank_<revision>.conf` will be merged into the board's default Kconfig configuration.
- The optional devicetree overlay `plank_<revision>.overlay` will be added to the common `plank.dts` devicetree file
- The `revision.cmake` file controls how the Zephyr build system matches the `<board>@<revision>` string specified by the user when building an application for the board.

Currently, `<revision>` can be either a numeric `MAJOR.MINOR.PATCH` style revision like `1.5.0`, or single letter like `A`, `B`, etc. Zephyr provides a CMake board extension function, `board_check_revision()`, to make it easy to match either style from `revision.cmake`.

Valid board revisions may be specified as arguments to the `board_check_revision()` function, like:

```
board_check_revision(FORMAT MAJOR.MINOR.PATCH
                     VALID_REVISIONS 0.1.0 0.3.0 ...
)
```

---

**Note:** `VALID_REVISIONS` can be omitted if all valid revisions have specific Kconfig fragments, such as `<board>_0_1_0.conf`, `<board>_0_3_0.conf`. This allows you to just place Kconfig revision fragments in the board folder and not have to keep the corresponding `VALID_REVISIONS` in sync.

---

The following sections describe how to support these styles of revision numbers.

**Numeric revisions** Let's say you want to add support for revisions `0.5.0`, `1.0.0`, and `1.5.0` of the plank board with both Kconfig fragments and devicetree overlays. Create `revision.cmake` with `board_check_revision(FORMAT MAJOR.MINOR.PATCH)`, and create the following additional files in the board directory:

```
boards/<ARCH>/plank
├─ plank_0_5_0.conf
├─ plank_0_5_0.overlay
├─ plank_1_0_0.conf
├─ plank_1_0_0.overlay
├─ plank_1_5_0.conf
├─ plank_1_5_0.overlay
└─ revision.cmake
```

Notice how the board files have changed periods (“.”) in the revision number to underscores (“\_”).

**Fuzzy numeric revision matching** To support “fuzzy” `MAJOR.MINOR.PATCH` revision matching for the plank board, use the following code in `revision.cmake`:

```
board_check_revision(FORMAT MAJOR.MINOR.PATCH)
```

If the user selects a revision between those available, the closest revision number that is not larger than the user's choice is used. For example, if the user builds for `plank@0.7.0`, the build system will target revision `0.5.0`.

The build system will print this at CMake configuration time:

```
-- Board: plank, Revision: 0.7.0 (Active: 0.5.0)
```

This allows you to only create revision configuration files for board revision numbers that introduce incompatible changes.

Any revision less than the minimum defined will be treated as an error.

You may use `0.0.0` as a minimum revision to build for by creating the file `plank_0_0_0.conf` in the board directory. This will be used for any revision lower than `0.5.0`, for example if the user builds for `plank@0.1.0`.

**Exact numeric revision matching** Alternatively, the `EXACT` keyword can be given to `board_check_revision()` in `revision.cmake` to allow exact matches only, like this:

```
board_check_revision(FORMAT MAJOR.MINOR.PATCH EXACT)
```

With this `revision.cmake`, building for `plank@0.7.0` in the above example will result in the following error message:

```
Board revision `0.7.0` not found. Please specify a valid board revision.
```

**Letter revision matching** Let's say instead that you need to support revisions A, B, and C of the `plank` board. Create the following additional files in the board directory:

```
boards/<ARCH>/plank
├── plank_A.conf
├── plank_A.overlay
├── plank_B.conf
├── plank_B.overlay
├── plank_C.conf
├── plank_C.overlay
└── revision.cmake
```

And add the following to `revision.cmake`:

```
board_check_revision(FORMAT LETTER)
```

### `board_check_revision()` details

```
board_check_revision(FORMAT <LETTER | MAJOR.MINOR.PATCH>
                    [EXACT]
                    [DEFAULT_REVISION <revision>]
                    [HIGHEST_REVISION <revision>]
                    [VALID_REVISIONS <revision> [<revision> ...]]
)
```

This function supports the following arguments:

- `FORMAT LETTER`: matches single letter revisions from A to Z only
- `FORMAT MAJOR.MINOR.PATCH`: matches exactly three digits. The command line allows for loose typing, that is `-DBOARD=<board>@1` and `-DBOARD=<board>@1.0` will be handled as `-DBOARD=<board>@1.0.0`. Kconfig fragment and devicetree overlay files must use full numbering to avoid ambiguity, so only `<board>_1_0_0.conf` and `<board>_1_0_0.overlay` are allowed.

- **EXACT**: if given, the revision is required to be an exact match. Otherwise, the closest matching revision not greater than the user's choice will be selected.
- **DEFAULT\_REVISION** `<revision>`: if given, `<revision>` is the default revision to use when user has not selected a revision number. If not given, the build system prints an error when the user does not specify a board revision.
- **HIGHEST\_REVISION**: if given, specifies the highest valid revision for a board. This can be used to ensure that a newer board cannot be used with an older Zephyr. For example, if the current board directory supports revisions 0.x.0-0.99.99 and 1.0.0-1.99.99, and it is expected that the implementation will not work with board revision 2.0.0, then giving **HIGHEST\_REVISION** 1.99.99 causes an error if the user builds using `<board>@2.0.0`.
- **VALID\_REVISIONS**: if given, specifies a list of revisions that are valid for this board. If this argument is not given, then each Kconfig fragment of the form `<board>_<revision>.conf` in the board folder will be used as a valid revision for the board.

### Custom revision.cmake files

Some boards may not use board revisions supported by `board_check_revision()`. To support revisions of any type, the file `revision.cmake` can implement custom revision matching without calling `board_check_revision()`.

To signal to the build system that it should use a different revision than the one specified by the user, `revision.cmake` can set the variable `ACTIVE_BOARD_REVISION` to the revision to use instead. The corresponding Kconfig files and devicetree overlays must be named `<board>_<ACTIVE_BOARD_REVISION>.conf` and `<board>_<ACTIVE_BOARD_REVISION>.overlay`.

For example, if the user builds for `plank@zero`, `revision.cmake` can set `ACTIVE_BOARD_REVISION` to one to use the files `plank_one.conf` and `plank_one.overlay`.

### Contributing your board

If you want to contribute your board to Zephyr, first – thanks!

There are some extra things you'll need to do:

1. Make sure you've followed all the [General recommendations](#). They are requirements for boards included with Zephyr.
2. Add documentation for your board using the template file `doc/templates/board.tmpl`. See [Documentation Generation](#) for information on how to build your documentation before submitting your pull request.
3. Prepare a pull request adding your board which follows the [Contribution Guidelines](#).

## 8.17.3 Shields

Shields, also known as “add-on” or “daughter boards”, attach to a board to extend its features and services for easier and modularized prototyping. In Zephyr, the shield feature provides Zephyr-formatted shield descriptions for easier compatibility with applications.

### Shield porting and configuration

Shield configuration files are available in the board directory under `/boards/shields`:

```
boards/shields/<shield>
├── <shield>.overlay
├── Kconfig.shield
└── Kconfig.defconfig
```

These files provides shield configuration as follows:

- **<shield>.overlay**: This file provides a shield description in devicetree format that is merged with the board's [devicetree](#) before compilation.
- **Kconfig.shield**: This file defines shield Kconfig symbols that will be used for default shield configuration. To ease use with applications, the default shield configuration here should be consistent with those in the [Write your devicetree](#).
- **Kconfig.defconfig**: This file defines the default shield configuration. It is made to be consistent with the [Write your devicetree](#). Hence, shield configuration should be done by keeping in mind that features activation is application responsibility.

## Board compatibility

Hardware shield-to-board compatibility depends on the use of well-known connectors used on popular boards (such as Arduino and 96boards). For software compatibility, boards must also provide a configuration matching their supported connectors.

This should be done at two different level:

- Pinmux: Connector pins should be correctly configured to match shield pins
- Devicetree: A board [devicetree](#) file, BOARD.dts should define a node alias for each connector interface. For example, for Arduino I2C:

```
#define arduino_i2c i2c1

aliases {
    arduino,i2c = &i2c1;
};
```

Note: With support of dtc v1.4.2, above will be replaced with the recently introduced overriding node element:

```
arduino_i2c:i2c1{};
```

**Board specific shield configuration** If modifications are needed to fit a shield to a particular board or board revision, you can override a shield description for a specific board by adding board or board revision overriding files to a shield, as follows:

```
boards/shields/<shield>
├── boards
│   ├── <board>_<revision>.overlay
│   ├── <board>.overlay
│   ├── <board>.defconfig
│   ├── <board>_<revision>.conf
│   └── <board>.conf
```

## Shield activation

Activate support for one or more shields by adding the matching -DSHIELD arg to CMake command

```
# From the root of the zephyr repository
west build -b None your_app -- -DSHIELD="x_nucleo_idb05a1 x_nucleo_iks01a1"
```

Alternatively, it could be set by default in a project's CMakeLists.txt:

```
set(SHIELD x_nucleo_iks01a1)
```

## Shield variants

Some shields may support several variants or revisions. In that case, it is possible to provide multiple version of the shields description:

```
boards/shields/<shield>
├── <shield_v1>.overlay
├── <shield_v1>.defconfig
├── <shield_v2>.overlay
└── <shield_v2>.defconfig
```

In this case, a shield-particular revision name can be used:

```
# From the root of the zephyr repository
west build -b None your_app -- -DSHIELD=shield_v2
```

You can also provide a board-specific configuration to a specific shield revision:

```
boards/shields/<shield>
├── <shield_v1>.overlay
├── <shield_v1>.defconfig
├── <shield_v2>.overlay
├── <shield_v2>.defconfig
└── boards
    └── <shield_v2>
        ├── <board>.overlay
        └── <board>.defconfig
```

## GPIO nexus nodes

GPIOs accessed by the shield peripherals must be identified using the shield GPIO abstraction, for example from the `arduino-header-r3` compatible. Boards that provide the header must map the header pins to SOC-specific pins. This is accomplished by including a [nexus node](#) that looks like the following into the board devicetree file:

```
arduino_header: connector {
    compatible = "arduino-header-r3";
    #gpio-cells = <2>;
    gpio-map-mask = <0xffffffff 0xffffffffc0>;
    gpio-map-pass-thru = <0 0x3f>;
    gpio-map = <0 0 &gpioa 0 0>, /* A0 */
               <1 0 &gpioa 1 0>, /* A1 */
               <2 0 &gpioa 4 0>, /* A2 */
               <3 0 &gpiob 0 0>, /* A3 */
               <4 0 &gpioc 1 0>, /* A4 */
               <5 0 &gpioc 0 0>, /* A5 */
               <6 0 &gpioa 3 0>, /* D0 */
               <7 0 &gpioa 2 0>, /* D1 */
}
```

(continues on next page)

(continued from previous page)

```

<8 0 &gpioa 10 0>, /* D2 */
<9 0 &gpiob 3 0>, /* D3 */
<10 0 &gpiob 5 0>, /* D4 */
<11 0 &gpiob 4 0>, /* D5 */
<12 0 &gpiob 10 0>, /* D6 */
<13 0 &gpioa 8 0>, /* D7 */
<14 0 &gpioa 9 0>, /* D8 */
<15 0 &gpioc 7 0>, /* D9 */
<16 0 &gpiob 6 0>, /* D10 */
<17 0 &gpioa 7 0>, /* D11 */
<18 0 &gpioa 6 0>, /* D12 */
<19 0 &gpioa 5 0>, /* D13 */
<20 0 &gpiob 9 0>, /* D14 */
<21 0 &gpiob 8 0>; /* D15 */
};

```

This specifies how Arduino pin references like `<&arduino_header 11 0>` are converted to SOC gpio pin references like `<&gpiob 4 0>`.

In Zephyr GPIO specifiers generally have two parameters (indicated by `#gpio-cells = <2>`): the pin number and a set of flags. The low 6 bits of the flags correspond to features that can be configured in devicetree. In some cases it's necessary to use a non-zero flag value to tell the driver how a particular pin behaves, as with:

```
drdy-gpios = <&arduino_header 11 GPIO_ACTIVE_LOW>;
```

After preprocessing this becomes `<&arduino_header 11 1>`. Normally the presence of such a flag would cause the map lookup to fail, because there is no map entry with a non-zero flags value. The `gpio-map-mask` property specifies that, for lookup, all bits of the pin and all but the low 6 bits of the flags are used to identify the specifier. Then the `gpio-map-pass-thru` specifies that the low 6 bits of the flags are copied over, so the SOC GPIO reference becomes `<&gpiob 4 1>` as intended.

See [nexus node](#) for more information about this capability.

## 8.18 Testing

### 8.18.1 Test Framework

The Zephyr Test Framework (Ztest) provides a simple testing framework intended to be used during development. It provides basic assertion macros and a generic test structure.

The framework can be used in two ways, either as a generic framework for integration testing, or for unit testing specific modules.

#### Quick start - Integration testing

A simple working base is located at [samples/subsys/testsuite/integration](#). Just copy the files to `tests/` and edit them for your needs. The test will then be automatically built and run by the `twister` script. If you are testing the **bar** component of **foo**, you should copy the sample folder to `tests/foo/bar`. It can then be tested with:

```
./scripts/twister -s tests/foo/bar/test-identifier
```

In the example above `tests/foo/bar` signifies the path to the test and the `test-identifier` references a test defined in the `testcase.yaml` file.

To run all tests defined in a test project, run:

```
./scripts/twister -T tests/foo/bar/
```

The sample contains the following files:

CMakeLists.txt

```
1 # SPDX-License-Identifier: Apache-2.0
2
3 cmake_minimum_required(VERSION 3.20.0)
4 find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
5 project(integration)
6
7 FILE(GLOB app_sources src/*.c)
8 target_sources(app PRIVATE ${app_sources})
```

testcase.yaml

```
1 tests:
2   # section.subsection
3   testing.ztest:
4     build_only: true
5     platform_allow: native_posix
6     tags: testing
```

prj.conf

```
1 CONFIG_ZTEST=y
```

src/main.c (see [best practices](#))

```
1 /*
2  * Copyright (c) 2016 Intel Corporation
3  *
4  * SPDX-License-Identifier: Apache-2.0
5  */
6
7 #include <ztest.h>
8
9 /**
10  * @brief Test Asserts
11  *
12  * This test verifies various assert macros provided by ztest.
13  *
14  */
15 static void test_assert(void)
16 {
17     zassert_true(1, "1 was false");
18     zassert_false(0, "0 was true");
19     zassert_is_null(NULL, "NULL was not NULL");
20     zassert_not_null("foo", "\"foo\" was NULL");
21     zassert_equal(1, 1, "1 was not equal to 1");
22     zassert_equal_ptr(NULL, NULL, "NULL was not equal to NULL");
23 }
24
25 void test_main(void)
26 {
27     ztest_test_suite(framework_tests,
28                     ztest_unit_test(test_assert))
```

(continues on next page)

(continued from previous page)

```

29     );
30
31     ztest_run_test_suite(framework_tests);
32 }

```

- [Listing Tests](#)
- [Skipping Tests](#)

A test case project may consist of multiple sub-tests or smaller tests that either can be testing functionality or APIs. Functions implementing a test should follow the guidelines below:

- Test cases function names should be prefix with **test\_**
- Test cases should be documented using doxygen
- Test function names should be unique within the section or component being tested

An example can be seen below:

```

/**
 * @brief Test Asserts
 *
 * This test verifies the zassert_true macro.
 */
static void test_assert(void)
{
    zassert_true(1, "1 was false");
}

```

The above test is then enabled as part of the testsuite using:

```
ztest_unit_test(test_assert)
```

**Listing Tests** Tests (test projects) in the Zephyr tree consist of many testcases that run as part of a project and test similar functionality, for example an API or a feature. The `twister` script can parse the testcases in all test projects or a subset of them, and can generate reports on a granular level, i.e. if cases have passed or failed or if they were blocked or skipped.

Twister parses the source files looking for test case names, so you can list all kernel test cases, for example, by entering:

```
twister --list-tests -T tests/kernel
```

**Skipping Tests** Special- or architecture-specific tests cannot run on all platforms and architectures, however we still want to count those and report them as being skipped. Because the test inventory and the list of tests is extracted from the code, adding conditionals inside the test suite is sub-optimal. Tests that need to be skipped for a certain platform or feature need to explicitly report a skip using `ztest_test_skip()`. If the test runs, it needs to report either a pass or fail. For example:

```

#ifdef CONFIG_TEST1
void test_test1(void)
{
    zassert_true(1, "true");
}
#else

```

(continues on next page)

(continued from previous page)

```
void test_test1(void)
{
    ztest_test_skip();
}
#endif

void test_main(void)
{
    ztest_test_suite(common,
                     ztest_unit_test(test_test1),
                     ztest_unit_test(test_test2)
                     );
    ztest_run_test_suite(common);
}
```

### Quick start - Unit testing

Ztest can be used for unit testing. This means that rather than including the entire Zephyr OS for testing a single function, you can focus the testing efforts into the specific module in question. This will speed up testing since only the module will have to be compiled in, and the tested functions will be called directly.

Since you won't be including basic kernel data structures that most code depends on, you have to provide function stubs in the test. Ztest provides some helpers for mocking functions, as demonstrated below.

In a unit test, mock objects can simulate the behavior of complex real objects and are used to decide whether a test failed or passed by verifying whether an interaction with an object occurred, and if required, to assert the order of that interaction.

**Best practices for declaring the test suite** *twister* and other validation tools need to obtain the list of subcases that a Zephyr *ztest* test image will expose.

---

### Rationale

This all is for the purpose of traceability. It's not enough to have only a semaphore test project. We also need to show that we have testpoints for all APIs and functionality, and we trace back to documentation of the API, and functional requirements.

The idea is that test reports show results for every sub-testcase as passed, failed, blocked, or skipped. Reporting on only the high-level test project level, particularly when tests do too many things, is too vague.

---

Here is a generic template for a test showing the expected use of `ztest_test_suite()`:

```
#include <ztest.h>

extern void test_sometest1(void);
extern void test_sometest2(void);
#ifdef CONFIG_WHATEVER /* Conditionally skip test_sometest3 */
void test_sometest3(void)
{
    ztest_test_skip();
}
#else
```

(continues on next page)

(continued from previous page)

```

extern void test_sometest3(void);
#endif
extern void test_sometest4(void);
...

void test_main(void)
{
    ztest_test_suite(common,
                      ztest_unit_test(test_sometest1),
                      ztest_unit_test(test_sometest2),
                      ztest_unit_test(test_sometest3),
                      ztest_unit_test(test_sometest4)
    );
    ztest_run_test_suite(common);
}

```

For *twister* to parse source files and create a list of subcases, the declarations of `ztest_test_suite()` must follow a few rules:

- one declaration per line
- conditional execution by using `ztest_test_skip()`

What to avoid:

- packing multiple testcases in one source file

```

void test_main(void)
{
    #ifdef TEST_feature1
        ztest_test_suite(feature1,
                          ztest_unit_test(test_1a),
                          ztest_unit_test(test_1b),
                          ztest_unit_test(test_1c)
        );
        ztest_run_test_suite(feature1);
    #endif

    #ifdef TEST_feature2
        ztest_test_suite(feature2,
                          ztest_unit_test(test_2a),
                          ztest_unit_test(test_2b)
        );
        ztest_run_test_suite(feature2);
    #endif
}

```

- Do not use `#if`

```

        ztest_test_suite(common,
                          ztest_unit_test(test_sometest1),
                          ztest_unit_test(test_sometest2),
    #ifdef CONFIG_WHATEVER
        ztest_unit_test(test_sometest3),
    #endif
        ztest_unit_test(test_sometest4),
        ...

```

- Do not add comments on lines with a call to `ztest_unit_test()`:

```
ztest_test_suite(common,
    ztest_unit_test(test_sometest1),
    ztest_unit_test(test_sometest2) /* will fail */,
    /* will fail! */ ztest_unit_test(test_sometest3),
    ztest_unit_test(test_sometest4),
    ...
```

- Do not define multiple definitions of unit / user unit test case per line

```
ztest_test_suite(common,
    ztest_unit_test(test_sometest1), ztest_unit_test(test_
    ↪sometest2),
    ztest_unit_test(test_sometest3),
    ztest_unit_test(test_sometest4),
    ...
```

Other questions:

- Why not pre-scan with CPP and then parse? or post scan the ELF file?

If C pre-processing or building fails because of any issue, then we won't be able to tell the subcases.

- Why not declare them in the YAML testcase description?

A separate testcase description file would be harder to maintain than just keeping the information in the test source files themselves – only one file to update when changes are made eliminates duplication.

## API reference

### Running tests

*group* `ztest_test`

This module eases the testing process by providing helpful macros and other testing structures.

### Defines

`ztest_unit_test_setup_teardown(fn, setup, teardown)`

Define a test with setup and teardown functions.

This should be called as an argument to `ztest_test_suite`. The test will be run in the following order: *setup*, *fn*, *teardown*.

#### Parameters

- *fn* – Main test function
- *setup* – Setup function
- *teardown* – Teardown function

`ztest_user_unit_test_setup_teardown(fn, setup, teardown)`

Define a user mode test with setup and teardown functions.

This should be called as an argument to `ztest_test_suite`. The test will be run in the following order: *setup*, *fn*, *teardown*. ALL test functions will be run in user mode, and only if `CONFIG_USERSPACE` is enabled, otherwise this is the same as `ztest_unit_test_setup_teardown()`.

#### Parameters

- *fn* – Main test function
- *setup* – Setup function

- `teardown` – Teardown function

`ztest_unit_test(fn)`

Define a test function.

This should be called as an argument to `ztest_test_suite`.

#### Parameters

- `fn` – Test function

`ztest_user_unit_test(fn)`

Define a test function that should run as a user thread.

This should be called as an argument to `ztest_test_suite`. If `CONFIG_USERSPACE` is not enabled, this is functionally identical to [`ztest\_unit\_test\(\)`](#).

#### Parameters

- `fn` – Test function

`ztest_1cpu_unit_test(fn)`

Define a SMP-unsafe test function.

As [`ztest\_unit\_test\(\)`](#), but ensures all test code runs on only one CPU when in SMP.

#### Parameters

- `fn` – Test function

`ztest_1cpu_user_unit_test(fn)`

Define a SMP-unsafe test function that should run as a user thread.

As [`ztest\_user\_unit\_test\(\)`](#), but ensures all test code runs on only one CPU when in SMP.

#### Parameters

- `fn` – Test function

`ZTEST_DMEM`

`ZTEST_BMEM`

`ZTEST_SECTION`

`ztest_test_suite(suite, ...)`

Define a test suite.

This function should be called in the following fashion:

```
ztest_test_suite(test_suite_name,
                 ztest_unit_test(test_function),
                 ztest_unit_test(test_other_function)
);

ztest_run_test_suite(test_suite_name);
```

#### Parameters

- `suite` – Name of the testing suite

```
ztest_run_test_suite(suite)
```

Run the specified test suite.

#### Parameters

- `suite` – Test suite to run.

### Functions

```
void ztest_test_fail(void)
```

Fail the currently running test.

This is the function called from failed assertions and the like. You probably don't need to call it yourself.

```
void ztest_test_pass(void)
```

Pass the currently running test.

Normally a test passes just by returning without an assertion failure. However, if the success case for your test involves a fatal fault, you can call this function from `k_sys_fatal_error_handler` to indicate that the test passed before aborting the thread.

```
void ztest_test_skip(void)
```

Skip the current test.

```
static inline void unit_test_noop(void)
```

Do nothing, successfully.

Unit test / setup function / teardown function that does nothing, successfully. Can be used as a parameter to [ztest\\_unit\\_test\\_setup\\_teardown\(\)](#).

### Variables

```
struct k\_mem\_partition ztest_mem_partition
```

**Assertions** These macros will instantly fail the test if the related assertion fails. When an assertion fails, it will print the current file, line and function, alongside a reason for the failure and an optional message. If the config option: `CONFIG_ZTEST_ASSERT_VERBOSE` is 0, the assertions will only print the file and line numbers, reducing the binary size of the test.

Example output for a failed macro from `zassert_equal(buf->ref, 2, "Invalid refcount")`:

```
Assertion failed at main.c:62: test_get_single_buffer: Invalid refcount (buf->ref not
↪equal to 2)
Aborted at unit test function
```

```
group ztest_assert
```

This module provides assertions when using Ztest.

### Defines

```
zassert(cond, default_msg, msg, ...)
```

Fail the test, if `cond` is false.

You probably don't need to call this macro directly. You should instead use `zassert_{condition}` macros below.

Note that when `CONFIG_MULTITHREADING=n` macro returns from the function. It is then expected that in that case `ztest` asserts will be used only in the context of the test function.

**Parameters**

- `cond` – Condition to check
- `msg` – Optional, can be `NULL`. Message to print if `cond` is false.
- `default_msg` – Message to print if `cond` is false

`zassert_unreachable(msg, ...)`

Assert that this function call won't be reached.

**Parameters**

- `msg` – Optional message to print if the assertion fails

`zassert_true(cond, msg, ...)`

Assert that `cond` is true.

**Parameters**

- `cond` – Condition to check
- `msg` – Optional message to print if the assertion fails

`zassert_false(cond, msg, ...)`

Assert that `cond` is false.

**Parameters**

- `cond` – Condition to check
- `msg` – Optional message to print if the assertion fails

`zassert_ok(cond, msg, ...)`

Assert that `cond` is 0 (success)

**Parameters**

- `cond` – Condition to check
- `msg` – Optional message to print if the assertion fails

`zassert_is_null(ptr, msg, ...)`

Assert that `ptr` is `NULL`.

**Parameters**

- `ptr` – Pointer to compare
- `msg` – Optional message to print if the assertion fails

`zassert_not_null(ptr, msg, ...)`

Assert that `ptr` is not `NULL`.

**Parameters**

- `ptr` – Pointer to compare
- `msg` – Optional message to print if the assertion fails

`zassert_equal(a, b, msg, ...)`

Assert that `a` equals `b`.

`a` and `b` won't be converted and will be compared directly.

**Parameters**

- `a` – Value to compare

- `b` – Value to compare
- `msg` – Optional message to print if the assertion fails

`zassert_not_equal(a, b, msg, ...)`

Assert that *a* does not equal *b*.

*a* and *b* won't be converted and will be compared directly.

#### Parameters

- `a` – Value to compare
- `b` – Value to compare
- `msg` – Optional message to print if the assertion fails

`zassert_equal_ptr(a, b, msg, ...)`

Assert that *a* equals *b*.

*a* and *b* will be converted to `void *` before comparing.

#### Parameters

- `a` – Value to compare
- `b` – Value to compare
- `msg` – Optional message to print if the assertion fails

`zassert_within(a, b, d, msg, ...)`

Assert that *a* is within *b* with delta *d*.

#### Parameters

- `a` – Value to compare
- `b` – Value to compare
- `d` – Delta
- `msg` – Optional message to print if the assertion fails

`zassert_mem_equal(...)`

Assert that 2 memory buffers have the same contents.

This macro calls the final memory comparison assertion macro. Using double expansion allows providing some arguments by macros that would expand to more than one values (ANSI-C99 defines that all the macro arguments have to be expanded before macro call).

#### Parameters

- ... – Arguments, see [zassert\\_mem\\_equal\\_\\_](#) for real arguments accepted.

`zassert_mem_equal__(buf, exp, size, msg, ...)`

Internal assert that 2 memory buffers have the same contents.

---

**Note:** This is internal macro, to be used as a second expansion. See [zassert\\_mem\\_equal](#).

---

#### Parameters

- `buf` – Buffer to compare
- `exp` – Buffer with expected contents
- `size` – Size of buffers
- `msg` – Optional message to print if the assertion fails

**Mocking** These functions allow abstracting callbacks and related functions and controlling them from specific tests. You can enable the mocking framework by setting `:kconfig: `CONFIG_ZTEST MOCKING`` to “y” in the configuration file of the test. The amount of concurrent return values and expected parameters is limited by `:kconfig: `CONFIG_ZTEST_PARAMETER_COUNT``.

Here is an example for configuring the function `expect_two_parameters` to expect the values `a=2` and `b=3`, and telling `returns_int` to return 5:

```

1  #include <ztest.h>
2
3  static void expect_two_parameters(int a, int b)
4  {
5      ztest_check_expected_value(a);
6      ztest_check_expected_value(b);
7  }
8
9  static void parameter_tests(void)
10 {
11     ztest_expect_value(expect_two_parameters, a, 2);
12     ztest_expect_value(expect_two_parameters, b, 3);
13     expect_two_parameters(2, 3);
14 }
15
16 static int returns_int(void)
17 {
18     return ztest_get_return_value();
19 }
20
21 static void return_value_tests(void)
22 {
23     ztest_returns_value(returns_int, 5);
24     zassert_equal(returns_int(), 5, NULL);
25 }
26
27 void test_main(void)
28 {
29     ztest_test_suite(mock_framework_tests,
30                     ztest_unit_test(parameter_test),
31                     ztest_unit_test(return_value_test)
32     );
33
34     ztest_run_test_suite(mock_framework_tests);
35 }

```

#### group ztest\_mock

This module provides simple mocking functions for unit testing. These need `CONFIG_ZTEST MOCKING=y`.

#### Defines

`ztest_expect_value(func, param, value)`

Tell function *func* to expect the value *value* for *param*.

When using `ztest_check_expected_value()`, tell that the value of *param* should be *value*. The value will internally be stored as an `uintptr_t`.

#### Parameters

- `func` – Function in question
- `param` – Parameter for which the value should be set
- `value` – Value for *param*

`ztest_check_expected_value(param)`

If *param* doesn't match the value set by `ztest_expect_value()`, fail the test.

This will first check that *param* has a value to be expected, and then checks whether the value of the parameter is equal to the expected value. If either of these checks fail, the current test will fail. This must be called from the called function.

#### Parameters

- `param` – Parameter to check

`ztest_expect_data(func, param, data)`

Tell function *func* to expect the data *data* for *param*.

When using `ztest_check_expected_data()`, the data pointed to by *param* should be same *data* in this function. Only data pointer is stored by this function, so it must still be valid when `ztest_check_expected_data` is called.

#### Parameters

- `func` – Function in question
- `param` – Parameter for which the data should be set
- `data` – pointer for the data for parameter *param*

`ztest_check_expected_data(param, length)`

If data pointed by *param* don't match the data set by `ztest_expect_data()`, fail the test.

This will first check that *param* is expected to be null or non-null and then check whether the data pointed by parameter is equal to expected data. If either of these checks fail, the current test will fail. This must be called from the called function.

#### Parameters

- `param` – Parameter to check
- `length` – Length of the data to compare

`ztest_return_data(func, param, data)`

Tell function *func* to return the data *data* for *param*.

When using `ztest_return_data()`, the data pointed to by *param* should be same *data* in this function. Only data pointer is stored by this function, so it must still be valid when `ztest_copy_return_data` is called.

#### Parameters

- `func` – Function in question
- `param` – Parameter for which the data should be set
- `data` – pointer for the data for parameter *param*

`ztest_copy_return_data(param, length)`

Copy the data set by `ztest_return_data` to the memory pointed by *param*.

This will first check that *param* is not null and then copy the data. This must be called from the called function.

#### Parameters

- `param` – Parameter to return data for
- `length` – Length of the data to return

`ztest_returns_value(func, value)`

Tell *func* that it should return *value*.

#### Parameters

- *func* – Function that should return *value*
- *value* – Value to return from *func*

`ztest_get_return_value()`

Get the return value for current function.

The return value must have been set previously with `ztest_returns_value()`. If no return value exists, the current test will fail.

**Returns** The value the current function should return

`ztest_get_return_value_ptr()`

Get the return value as a pointer for current function.

The return value must have been set previously with `ztest_returns_value()`. If no return value exists, the current test will fail.

**Returns** The value the current function should return as a void \*

## Customizing Test Output

The way output is presented when running tests can be customized. An example can be found in `tests/ztest/custom_output`.

Customization is enabled by setting `:kconfig: `CONFIG_ZTEST_TC_UTIL_USER_OVERRIDE`` to “y” and adding a file `tc_util_user_override.h` with your overrides.

Add the line `zephyr_include_directories(my_folder)` to your project’s `CMakeLists.txt` to let Zephyr find your header file during builds.

See the file `subsys/testsuite/include/tc_util.h` to see which macros and/or defines can be overridden. These will be surrounded by blocks such as:

```
#ifndef SOMETHING
#define SOMETHING <default implementation>
#endif /* SOMETHING */
```

### 8.18.2 Test Runner (Twister)

This script scans for the set of unit test applications in the git repository and attempts to execute them. By default, it tries to build each test case on boards marked as default in the board definition file.

The default options will build the majority of the tests on a defined set of boards and will run in an emulated environment if available for the architecture or configuration being tested.

In normal use, twister runs a limited set of kernel tests (inside an emulator). Because of its limited test execution coverage, twister cannot guarantee local changes will succeed in the full build environment, but it does sufficient testing by building samples and tests for different boards and different configurations to help keep the complete code tree buildable.

When using (at least) one `-v` option, twister’s console output shows for every test how the test is run (`qemu`, `native_posix`, etc.) or whether the binary was just built. There are a few reasons why twister only builds a test and doesn’t run it:

- The test is marked as `build_only: true` in its `.yaml` configuration file.
- The test configuration has defined a harness but you don’t have it or haven’t set it up.

- The target device is not connected and not available for flashing
- You or some higher level automation invoked twister with `--build-only`.

These also affect the outputs of `--testcase-report` and `--detailed-report`, see their respective `--help` sections.

To run the script in the local tree, follow the steps below:

```
$ source zephyr-env.sh
$ ./scripts/twister
```

If you have a system with a large number of cores, you can build and run all possible tests using the following options:

```
$ ./scripts/twister --all --enable-slow
```

This will build for all available boards and run all applicable tests in a simulated (for example QEMU) environment.

The list of command line options supported by twister can be viewed using:

```
$ ./scripts/twister --help
```

## Board Configuration

To build tests for a specific board and to execute some of the tests on real hardware or in an emulation environment such as QEMU a board configuration file is required which is generic enough to be used for other tasks that require a board inventory with details about the board and its configuration that is only available during build time otherwise.

The board metadata file is located in the board directory and is structured using the YAML markup language. The example below shows a board with a data required for best test coverage for this specific board:

```
identifier: frdm_k64f
name: NXP FRDM-K64F
type: mcu
arch: arm
toolchain:
  - zephyr
  - gnuarmemb
  - xtools
supported:
  - arduino_gpio
  - arduino_i2c
  - netif:eth
  - adc
  - i2c
  - nvs
  - spi
  - gpio
  - usb_device
  - watchdog
  - can
  - pwm
testing:
  default: true
```

**identifier:** A string that matches how the board is defined in the build system. This same string is used when building, for example when calling `west build` or `cmake`:

```
# with west
west build -b reel_board
# with cmake
cmake -DBOARD=reel_board ..
```

**name:** The actual name of the board as it appears in marketing material.

**type:** Type of the board or configuration, currently we support 2 types: mcu, qemu

**arch:** Architecture of the board

**toolchain:** The list of supported toolchains that can build this board. This should match one of the values used for 'ZEPHYR\_TOOLCHAIN\_VARIANT' when building on the command line

**ram:** Available RAM on the board (specified in KB). This is used to match testcase requirements. If not specified we default to 128KB.

**flash:** Available FLASH on the board (specified in KB). This is used to match testcase requirements. If not specified we default to 512KB.

**supported:** A list of features this board supports. This can be specified as a single word feature or as a variant of a feature class. For example:

```
supported:
- pci
```

This indicates the board does support PCI. You can make a testcase build or run only on such boards, or:

```
supported:
- netif:eth
- sensor:bmi16
```

A testcase can both depend on 'eth' to only test ethernet or on 'netif' to run on any board with a networking interface.

**testing:** testing relating keywords to provide best coverage for the features of this board.

**default:** [True|False]: This is a default board, it will be tested with the highest priority and is covered when invoking the simplified twister without any additional arguments.

**ignore\_tags:** Do not attempt to build (and therefore run) tests marked with this list of tags.

**only\_tags:** Only execute tests with this list of tags on a specific platform.

## Test Cases

Test cases are detected by the presence of a 'testcase.yaml' or a 'sample.yaml' files in the application's project directory. This file may contain one or more entries in the test section each identifying a test scenario.

The name of each testcase needs to be unique in the context of the overall testsuite and has to follow basic rules:

1. The format of the test identifier shall be a string without any spaces or special characters (allowed characters: alphanumeric and [\_=]) consisting of multiple sections delimited with a dot (.).
2. Each test identifier shall start with a section followed by a subsection separated by a dot. For example, a test that covers semaphores in the kernel shall start with `kernel.semaphore`.
3. All test identifiers within a testcase.yaml file need to be unique. For example a testcase.yaml file covering semaphores in the kernel can have:
  - `kernel.semaphore`: For general semaphore tests

- `kernel.semaphore.stress`: Stress testing semaphores in the kernel.
4. Depending on the nature of the test, an identifier can consist of at least two sections:
- Ztest tests: The individual testcases in the ztest testsuite will be concatenated to identifier in the testcase.yaml file generating unique identifiers for every testcase in the suite.
  - Standalone tests and samples: This type of test should at least have 3 sections in the test identifier in the testcase.yaml (or sample.yaml) file. The last section of the name shall signify the test itself.

Test cases are written using the YAML syntax and share the same structure as samples. The following is an example test with a few options that are explained in this document.

```
tests:
  bluetooth.gatt:
    build_only: true
    platform_allow: qemu_cortex_m3 qemu_x86
    tags: bluetooth
  bluetooth.gatt.br:
    build_only: true
    extra_args: CONF_FILE="prj_br.conf"
    filter: not CONFIG_DEBUG
    platform_exclude: up_squared
    platform_allow: qemu_cortex_m3 qemu_x86
    tags: bluetooth
```

A sample with tests will have the same structure with additional information related to the sample and what is being demonstrated:

```
sample:
  name: hello world
  description: Hello World sample, the simplest Zephyr application
tests:
  sample.basic.hello_world:
    build_only: true
    tags: tests
    min_ram: 16
  sample.basic.hello_world.singlethread:
    build_only: true
    extra_args: CONF_FILE=prj_single.conf
    filter: not CONFIG_BT
    tags: tests
    min_ram: 16
```

The full canonical name for each test case is:

```
<path to test case>/<test entry>
```

Each test block in the testcase meta data can define the following key/value pairs:

**tags:** <list of tags> **(required)** A set of string tags for the testcase. Usually pertains to functional domains but can be anything. Command line invocations of this script can filter the set of tests to run based on tag.

**skip:** <True|False> **(default False)** skip testcase unconditionally. This can be used for broken tests.

**slow:** <True|False> **(default False)** Don't run this test case unless `--enable-slow` was passed in on the command line. Intended for time-consuming test cases that are only run under certain circumstances, like daily builds. These test cases are still compiled.

**extra\_args:** <list of extra arguments> Extra arguments to pass to Make when building or running the test case.

**extra\_configs:** <list of extra configurations> Extra configuration options to be merged with a master prj.conf when building or running the test case. For example:

```
common:
  tags: drivers adc
tests:
  test:
    depends_on: adc
  test_async:
    extra_configs:
      - CONFIG_ADC_ASYNC=y
```

**build\_only:** <True|False> (default False) If true, don't try to run the test even if the selected platform supports it.

**build\_on\_all:** <True|False> (default False) If true, attempt to build test on all available platforms.

**depends\_on:** <list of features> A board or platform can announce what features it supports, this option will enable the test only those platforms that provide this feature.

**min\_ram:** <integer> minimum amount of RAM in KB needed for this test to build and run. This is compared with information provided by the board metadata.

**min\_flash:** <integer> minimum amount of ROM in KB needed for this test to build and run. This is compared with information provided by the board metadata.

**timeout:** <number of seconds> Length of time to run test in QEMU before automatically killing it. Default to 60 seconds.

**arch\_allow:** <list of arches, such as x86, arm, arc> Set of architectures that this test case should only be run for.

**arch\_exclude:** <list of arches, such as x86, arm, arc> Set of architectures that this test case should not run on.

**platform\_allow:** <list of platforms> Set of platforms that this test case should only be run for. Do not use this option to limit testing or building in CI due to time or resource constraints, this option should only be used if the test or sample can only be run on the allowed platform and nothing else.

**integration\_platforms:** <YML list of platforms/boards> This option limits the scope to the listed platforms when twister is invoked with the `-integration` option. Use this instead of `platform_allow` if the goal is to limit scope due to timing or resource constraints.

**platform\_exclude:** <list of platforms> Set of platforms that this test case should not run on.

**extra\_sections:** <list of extra binary sections> When computing sizes, twister will report errors if it finds extra, unexpected sections in the Zephyr binary unless they are named here. They will not be included in the size calculation.

**harness:** <string> A harness string needed to run the tests successfully. This can be as simple as a loopback wiring or a complete hardware test setup for sensor and IO testing. Usually pertains to external dependency domains but can be anything such as console, sensor, net, keyboard, Bluetooth or pytest.

**harness\_config:** <harness configuration options> Extra harness configuration options to be used to select a board and/or for handling generic Console with regex matching. Config can announce what features it supports. This option will enable the test to run on only those platforms that fulfill this external dependency.

The following options are currently supported:

**type:** <one\_line|multi\_line> (required) Depends on the regex string to be matched

**record:** <recording options>

**regex:** <expression> (required) Any string that the particular test case prints to record test results.

**regex:** <expression> (required) Any string that the particular test case prints to confirm test runs as expected.

**ordered:** <True|False> (default False) Check the regular expression strings in orderly or randomly fashion

**repeat:** <integer> Number of times to validate the repeated regex expression

**fixture:** <expression> Specify a test case dependency on an external device(e.g., sensor), and identify setups that fulfill this dependency. It depends on specific test setup and board selection logic to pick the particular board(s) out of multiple boards that fulfill the dependency in an automation setup based on “fixture” keyword. Some sample fixture names are i2c\_hts221, i2c\_bme280, i2c\_FRAM, ble\_fw and gpio\_loop.

Only one fixture can be defined per testcase.

**pytest\_root:** <pytest directory> (default pytest) Specify a pytest directory which need to excute when test case begin to running, default pytest directory name is pytest, after pytest finished, twister will check if this case pass or fail according the pytest report.

The following is an example yaml file with a few harness\_config options.

```
sample:
  name: HTS221 Temperature and Humidity Monitor
common:
  tags: sensor
  harness: console
  harness_config:
    type: multi_line
    ordered: false
    regex:
      - "Temperature:(.*)C"
      - "Relative Humidity:(.*)%"
    fixture: i2c_hts221
tests:
  test:
    tags: sensors
    depends_on: i2c
```

The following is an example yaml file with pytest harness\_config options, default pytest\_root name “pytest” will be used if pytest\_root not specified. please refer the example in samples/subsys/testsuite/pytest/.

```
tests:
  pytest.example:
    harness: pytest
    harness_config:
      pytest_root: [pytest directory name]
```

**filter:** <expression> Filter whether the testcase should be run by evaluating an expression against an environment containing the following values:

```
{ ARCH : <architecture>,
  PLATFORM : <platform>,
  <all CONFIG_* key/value pairs in the test's generated defconfig>,
  *<env>: any environment variable available
}
```

The grammar for the expression language is as follows:

**expression ::= expression “and” expression**

expression “or” expression

“not” expression  
“(” expression “)”  
symbol “=” constant  
symbol “!” constant  
symbol “<” number  
symbol “>” number  
symbol “>=” number  
symbol “<=” number  
symbol “in” list  
symbol “:” string  
symbol

list ::= “[” list\_contents “]”

**list\_contents ::= constant**

list\_contents “,” constant

**constant ::= number**

string

For the case where expression ::= symbol, it evaluates to true if the symbol is defined to a non-empty string.

Operator precedence, starting from lowest to highest:

or (left associative) and (left associative) not (right associative) all comparison operators  
(non-associative)

arch\_allow, arch\_exclude, platform\_allow, platform\_exclude are all syntactic sugar for these expressions. For instance

arch\_exclude = x86 arc

Is the same as:

filter = not ARCH in [“x86”, “arc”]

The ‘:’ operator compiles the string argument as a regular expression, and then returns a true value only if the symbol’s value in the environment matches. For example, if CONFIG\_SOC=”stm32f107xc” then

filter = CONFIG\_SOC : “stm.\*”

Would match it.

The set of test cases that actually run depends on directives in the testcase file and options passed in on the command line. If there is any confusion, running with -v or examining the discard report (twister\_discard.csv) can help show why particular test cases were skipped.

Metrics (such as pass/fail state and binary size) for the last code release are stored in scripts/release/twister\_last\_release.csv. To update this, pass the -all -release options.

To load arguments from a file, write ‘+’ before the file name, e.g., +file\_name. File content must be one or more valid arguments separated by line break instead of white spaces.

Most everyday users will run with no arguments.

## Running in Integration Mode

This mode is used in continuous integration (CI) and other automated environments used to give developers fast feedback on changes. The mode can be activated using the -integration option of twister and narrows down the scope of builds and tests if applicable to platforms defined under the integration keyword in the testcase definition file (testcase.yaml and sample.yaml).

## Running Tests on Hardware

Beside being able to run tests in QEMU and other simulated environments, twister supports running most of the tests on real devices and produces reports for each run with detailed FAIL/PASS results.

**Executing tests on a single device** To use this feature on a single connected device, run twister with the following new options:

```
scripts/twister --device-testing --device-serial /dev/ttyACM0 -p \
frdm_k64f -T tests/kernel
```

The `--device-serial` option denotes the serial device the board is connected to. This needs to be accessible by the user running twister. You can run this on only one board at a time, specified using the `--platform` option.

**Executing tests on multiple devices** To build and execute tests on multiple devices connected to the host PC, a hardware map needs to be created with all connected devices and their details such as the serial device and their IDs if available. Run the following command to produce the hardware map:

```
./scripts/twister --generate-hardware-map map.yml
```

The generated hardware map file (`map.yml`) will have the list of connected devices, for example:

```
- connected: true
  id: OSHW000032254e4500128002ab98002784d1000097969900
  platform: unknown
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: /dev/cu.usbmodem146114202
- connected: true
  id: 000683759358
  platform: unknown
  product: J-Link
  runner: unknown
  serial: /dev/cu.usbmodem0006837593581
```

Any options marked as ‘unknown’ need to be changed and set with the correct values, in the above example both the platform names and the runners need to be replaced with the correct values corresponding to the connected hardware. In this example we are using a `reel_board` and an `nrf52840dk_nrf52840`:

```
- connected: true
  id: OSHW000032254e4500128002ab98002784d1000097969900
  platform: reel_board
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: /dev/cu.usbmodem146114202
- connected: true
  id: 000683759358
  platform: nrf52840dk_nrf52840
  product: J-Link
  runner: nrfjprog
  serial: /dev/cu.usbmodem0006837593581
```

If the map file already exists, then new entries are added and existing entries will be updated. This way you can use one single master hardware map and update it for every run to get the correct serial devices and status of the devices.

With the hardware map ready, you can run any tests by pointing to the map file:

```
./scripts/twister --device-testing --hardware-map map.yml -T samples/hello_world/
```

The above command will result in twister building tests for the platforms defined in the hardware map and subsequently flashing and running the tests on those platforms.

---

**Note:** Currently only boards with support for both pyocd and nrfjprog are supported with the hardware map features. Boards that require other runners to flash the Zephyr binary are still work in progress.

---

**Fixtures** Some tests require additional setup or special wiring specific to the test. Running the tests without this setup or test fixture may fail. A testcase can specify the fixture it needs which can then be matched with hardware capability of a board and the fixtures it supports via the command line or using the hardware map file.

Fixtures are defined in the hardware map file as a list:

```
- connected: true
  fixtures:
    - gpio_loopback
    id: 0240000026334e450015400f5e0e000b4eb1000097969900
    platform: frdm_k64f
    product: DAPLink CMSIS-DAP
    runner: pyocd
    serial: /dev/ttyACM9
```

When running *Test Runner (Twister)* with `--device-testing`, the configured fixture in the hardware map file will be matched to testcases requesting the same fixtures and these tests will be executed on the boards that provide this fixture.

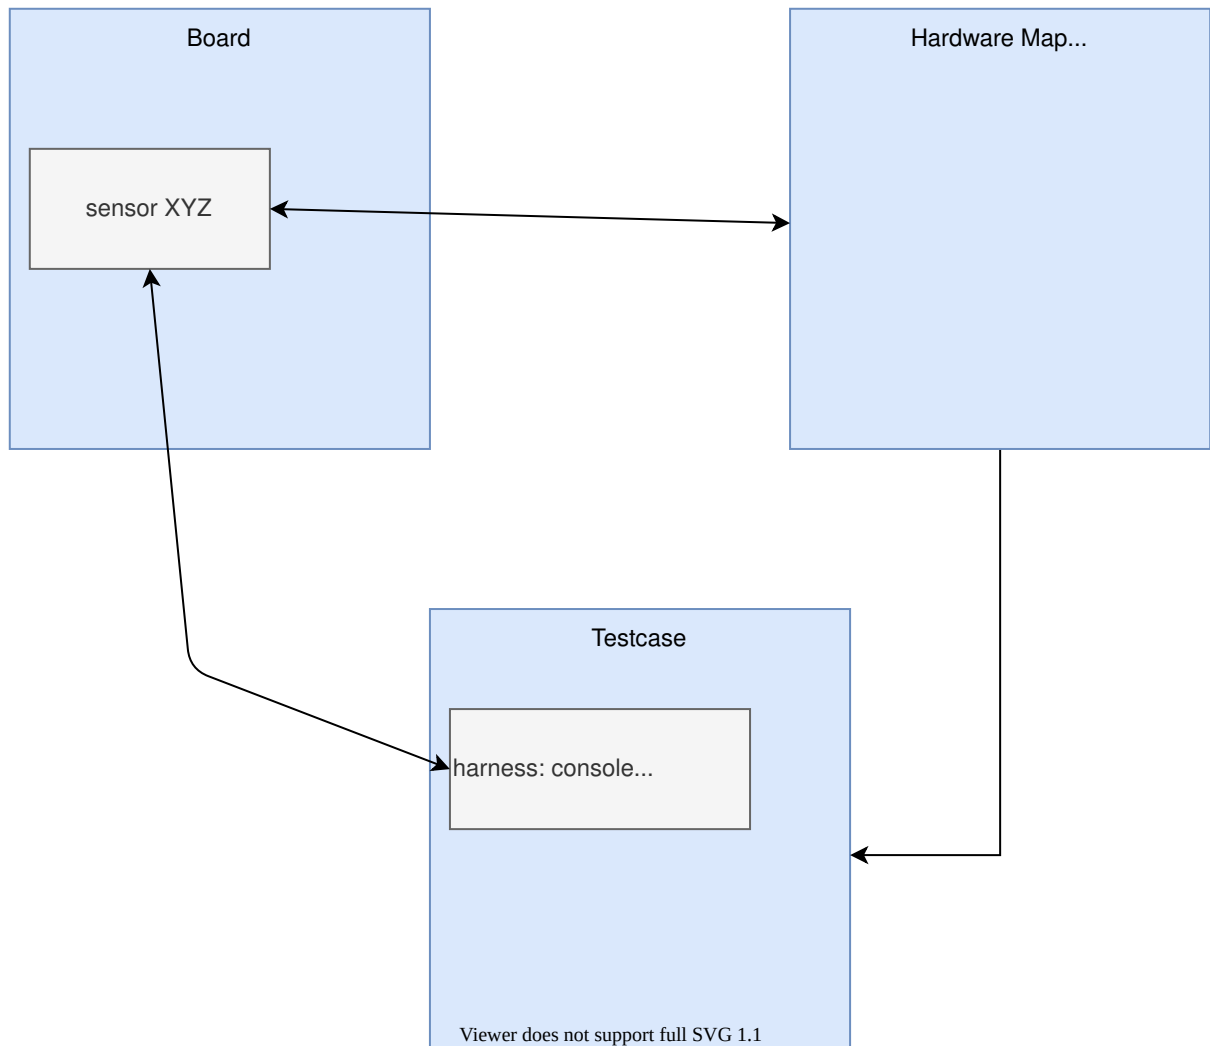

**Notes** It may be useful to annotate board descriptions in the hardware map file with additional information. Use the “notes” keyword to do this. For example:

```
- connected: false
  fixtures:
    - gpio_loopback
    id: 000683290670
  notes: An nrf5340dk_nrf5340 is detected as an nrf52840dk_nrf52840 with no serial
        port, and three serial ports with an unknown platform. The board id of the serial
        ports is not the same as the board id of the the development kit. If you
        ↪regenerate
        this file you will need to update serial to reference the third port, and platform
        to nrf5340dk_nrf5340_cpuapp or another supported board target.
  platform: nrf52840dk_nrf52840
  product: J-Link
  runner: jlink
  serial: null
```

**Overriding Board Identifier** When (re-)generated the hardware map file will contain an “id” keyword that serves as the argument to `--board-id` when flashing. In some cases the detected ID is not the correct one to use, for example when using an external J-Link probe. The “probe\_id” keyword overrides the “id” keyword for this purpose. For example:

```
- connected: false
  id: 0229000005d9ebc60000000000000000000000000000097969905
  platform: mimxrt1060_evk
```

(continues on next page)

(continued from previous page)

```
probe_id: 000609301751
product: DAPLink CMSIS-DAP
runner: jlink
serial: null
```

**Quarantine** Twister allows using user-defined yaml files defining the list of tests to be put under quarantine. Such tests will be skipped and marked accordingly in the output reports. This feature is especially useful when running larger test suits, where a failure of one test can affect the execution of other tests (e.g. putting the physical board in a corrupted state).

To use the quarantine feature one has to add the argument `--quarantine-list <PATH_TO_QUARANTINE_YAML>` to a twister call. The current status of tests on the quarantine list can also be verified by adding `--quarantine-verify` to the above argument. This will make twister skip all tests which are not on the given list.

A quarantine yaml has to be a sequence of dictionaries. Each dictionary has to have “scenarios” and “platforms” entries listing combinations of scenarios and platforms to put under quarantine. In addition, an optional entry “comment” can be used, where some more details can be given (e.g. link to a reported issue). These comments will also be added to the output reports.

An example of entries in a quarantine yaml:

```
- scenarios:
  - sample.basic.helloworld
  platforms:
  - all
  comment: "Link to the issue: https://github.com/zephyrproject-rtos/zephyr/pull/33287
↪"

- scenarios:
  - kernel.common
  - kernel.common.misra
  - kernel.common.nano64
  platforms:
  - qemu_cortex_m3
  - native_posix
```

### 8.18.3 Generating coverage reports

With Zephyr, you can generate code coverage reports to analyze which parts of the code are covered by a given test or application.

You can do this in two ways:

- In a real embedded target or QEMU, using Zephyr’s gcov integration
- Directly in your host computer, by compiling your application targeting the POSIX architecture

#### Test coverage reports in embedded devices or QEMU

**Overview** **GCC GCOV** is a test coverage program used together with the GCC compiler to analyze and create test coverage reports for your programs, helping you create more efficient, faster running code and discovering untested code paths

In Zephyr, gcov collects coverage profiling data in RAM (and not to a file system) while your application is running. Support for gcov collection and reporting is limited by available RAM size and so is currently enabled only for QEMU emulation of embedded targets.

**Details** There are 2 parts to enable this feature. The first is to enable the coverage for the device and the second to enable in the test application. As explained earlier the code coverage with gcov is a function of RAM available. Therefore ensure that the device has enough RAM when enabling the coverage for it. For example a small device like frdm\_k64f can run a simple test application but the more complex test cases which consume more RAM will crash when coverage is enabled.

To enable the device for coverage, select **:kconfig: `CONFIG\_HAS\_COVERAGE\_SUPPORT`** in the Kconfig.board file.

To report the coverage for the particular test application set **:kconfig: `CONFIG\_COVERAGE`**.

**Steps to generate code coverage reports** These steps will produce an HTML coverage report for a single application.

1. Build the code with CONFIG\_COVERAGE=y.

```
west build -b mps2_an385 -- -DCONFIG_COVERAGE=y
```

2. Capture the emulator output into a log file. You may need to terminate the emulator with Ctrl-A X for this to complete after the coverage dump has been printed:

```
ninja -Cbuild run | tee log.log
```

or

```
ninja -Cbuild run | tee log.log
```

3. Generate the gcov .gcda and .gcno files from the log file that was saved:

```
$ python3 scripts/gen_gcov_files.py -i log.log
```

4. Find the gcov binary placed in the SDK. You will need to pass the path to the gcov binary for the appropriate architecture when you later invoke gcovr:

```
$ find $ZEPHYR_SDK_INSTALL_DIR -iregex ".*gcov"
```

5. Create an output directory for the reports:

```
$ mkdir -p gcov_report
```

6. Run gcovr to get the reports:

```
$ gcovr -r $ZEPHYR_BASE . --html -o gcov_report/coverage.html --html-details --  
→gcov-executable <gcov_path_in_SDK>
```

## Coverage reports using the POSIX architecture

When compiling for the POSIX architecture, you utilize your host native tooling to build a native executable which contains your application, the Zephyr OS, and some basic HW emulation.

That means you can use the same tools you would while developing any other desktop application.

To build your application with gcc's gcov, simply set **:kconfig: `CONFIG\_COVERAGE`** before compiling it. When you run your application, gcov coverage data will be dumped into the respective gcda and gcno files. You may postprocess these with your preferred tools. For example:

```
west build -b native_posix samples/hello_world -- -DCONFIG_COVERAGE=y
```

```
$ ./build/zephyr/zephyr.exe
# Press Ctrl+C to exit
lcov --capture --directory ./ --output-file lcov.info -q --rc lcov_branch_coverage=1
genhtml lcov.info --output-directory lcov_html -q --ignore-errors source --branch-
↳ coverage --highlight --legend
```

**Note:** You need a recent version of `lcov` (at least 1.14) with support for intermediate text format. Such packages exist in recent Linux distributions.

Alternatively, you can use `gcovr` (at least version 4.2).

## Coverage reports using Twister

Zephyr's *twister script* can automatically generate a coverage report from the tests which were executed. You just need to invoke it with the `--coverage` command line option.

For example, you may invoke:

```
$ twister --coverage -p qemu_x86 -T tests/kernel
```

or:

```
$ twister --coverage -p native_posix -T tests/bluetooth
```

which will produce `twister-out/coverage/index.html` with the report.

The process differs for unit tests, which are built with the host toolchain and require a different board:

```
$ twister --coverage -p unit_testing -T tests/unit
```

which produces a report in the same location as non-unit testing.

## 8.19 Trusted Firmware-M

### 8.19.1 Trusted Firmware-M Overview

**Trusted Firmware-M (TF-M)** is a reference implementation of the Platform Security Architecture (PSA) **IoT Security Framework**. It defines and implements an architecture and a set of software components that aim to address some of the main security concerns in IoT products.

Zephyr RTOS has been PSA Certified since Zephyr 2.0.0 with TF-M 1.0, and is currently integrated with TF-M 1.3.0.

#### What Does TF-M Offer?

Through a set of secure services and by design, TF-M provides:

- Isolation of secure and non-secure resources
- Embedded-appropriate crypto
- Management of device secrets (keys, etc.)
- Firmware verification (and encryption)
- Protected off-chip data storage and retrieval
- Proof of device identity (device attestation)

- Audit logging

## Build System Integration

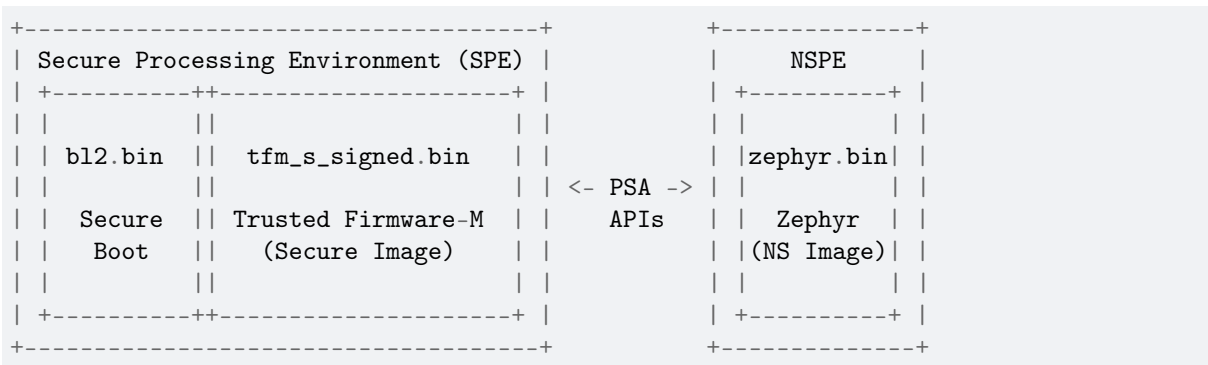

When using TF-M with a supported platform, TF-M will be automatically built and link in the background as part of the standard Zephyr build process. This build process makes a number of assumptions about how TF-M is being used, and has certain implications about what the Zephyr application image can and can not do:

- The secure processing environment (secure boot and TF-M) starts first
- Resource allocation for Zephyr relies on choices made in the secure image.

## Architecture Overview

A TF-M application will, generally, have the following three parts, from most to least trusted, left-to-right, with code execution happening in the same order (secure boot > secure image > ns image).

While the secure bootloader is optional, it is enabled by default, and secure boot is an important part of providing a secure solution:

Communication between the (Zephyr) Non-Secure Processing Environment (NSPE) and the (TF-M) Secure Processing Environment image happens based on a set of PSA APIs, and normally makes use of an IPC mechanism that is included as part of the TF-M build, and implemented in Zephyr (see [modules/trusted-firmware-m/interface](#)).

**Root of Trust (RoT) Architecture** TF-M is based upon a **Root of Trust (RoT)** architecture. This allows for hierarchies of trust from most, to less, to least trusted, providing a sound foundation upon which to build or access trusted services and resources.

The benefit of this approach is that less trusted components are prevented from accessing or compromising more critical parts of the system, and error conditions in less trusted environments won't corrupt more trusted, isolated resources.

The following RoT hierarchy is defined for TF-M, from most to least trusted:

- PSA Root of Trust (**PRoT**), which consists of:
  - PSA Immutable Root of Trust: secure boot
  - PSA Updateable Root of Trust: most trusted secure services
- Application Root of Trust (**ARoT**): isolated secure services

The **PSA Immutable Root of Trust** is the most trusted piece of code in the system, to which subsequent Roots of Trust are anchored. In TF-M, this is the secure boot image, which verifies that the secure and non-secure images are valid, have not been tampered with, and come from a reliable source. The secure bootloader also verifies new images during the firmware update process, thanks to the public signing key(s) built into it. As the name implies, this image is **immutable**.

The **PSA Updateable Root of Trust** implements the most trusted secure services and components in TF-M, such as the Secure Partition Manager (SPM), and shared secure services like PSA Crypto, Internal Trusted Storage (ITS), etc. Services in the PSA Updateable Root of Trust have access to other resources in the same Root of Trust.

The **Application Root of Trust** is a reduced-privilege area in the secure processing environment which, depending on the isolation level chosen when building TF-M, has limited access to the PProT, or even other ARoT services at the highest isolation levels. Some standard services exist in the ARoT, such as Protected Storage (PS), and generally custom secure services that you implement should be placed in the ARoT, unless a compelling reason is present to place them in the PProT.

These divisions are distinct from the **untrusted code**, which runs in the non-secure environment, and has the least privilege in the system. This is the Zephyr application image in this case.

**Isolation Levels** At present, there are three distinct **isolation levels** defined in TF-M, with increasingly rigid boundaries between regions. The isolation level used will depend on your security requirements, and the system resources available to you.

- **Isolation Level 1** is the lowest isolation level, and the only major boundary is between the secure and non-secure processing environment, usually by means of Arm TrustZone on Armv8-M processors. There is no distinction here between the PSA Updateable Root of Trust (PProT) and the Application Root of Trust (ARoT). They execute at the same privilege level. This isolation level will lead to the smallest combined application images.
- **Isolation Level 2** builds upon level one by introducing a distinction between the PSA Updateable Root of Trust and the Application Root of Trust, where ARoT services have limited access to PProT services, and can only communicate with them through public APIs exposed by the PProT services. ARoT services, however, are not strictly isolated from one another.
- **Isolation Level 3** is the highest isolation level, and builds upon level 2 by isolating ARoT services from each other, so that each ARoT is essentially silo'ed from other services. This provides the highest level of isolation, but also comes at the cost of additional overhead and code duplication between services.

The current isolation level can be checked via `:kconfig: 'CONFIG_TFM_ISOLATION_LEVEL'`.

**Secure Boot** The default secure bootloader in TF-M is based on **MCUBoot**, and is referred to as BL2 in TF-M (for the second-stage bootloader, potentially after a HW-based bootloader on the secure MCU, etc.).

All images in TF-M are hashed and signed, with the hash and signature verified by MCUBoot during the firmware update process.

Some key features of MCUBoot as used in TF-M are:

- Public signing key(s) are baked into the bootloader
- S and NS images can be signed using different keys
- Firmware images can optionally be encrypted
- Client software is responsible for writing a new image to the secondary slot
- By default, uses static flash layout of two identically-sized memory regions
- Optional security counter for rollback protection

When dealing with (optionally) encrypted images:

- Only the payload is encrypted (header, TLVs are plain text)
- Hashing and signing are applied over the un-encrypted data
- Uses AES-CTR-128 or AES-CTR-256 for encryption
- Encryption key randomized every encryption cycle (via `imgtool`)

- The AES-CTR key is included in the image and can be encrypted using:
  - RSA-OAEP
  - AES-KW (128 or 256 bits depending on the AES-CTR key length)
  - ECIES-P256
  - ECIES-X25519

Key config properties to control secure boot in Zephyr are:

- `:kconfig: `CONFIG_TFM_BL2`` toggles the bootloader (default = y).
- `:kconfig: `CONFIG_TFM_KEY_FILE_S`` overrides the secure signing key.
- `:kconfig: `CONFIG_TFM_KEY_FILE_NS`` overrides the non-secure signing key.

**Secure Processing Environment** Once the secure bootloader has finished executing, a TF-M based secure image will begin execution in the **secure processing environment**. This is where our device will be initially configured, and any secure services will be initialised.

Note that the starting state of our device is controlled by the secure firmware, meaning that when the non-secure Zephyr application starts, peripherals may not be in the HW-default reset state. In case of doubts, be sure to consult the board support packages in TF-M, available in the `platform/ext/target/` folder of the TF-M module (which is in `modules/tee/tfm/trusted-firmware-m/` within a default Zephyr west workspace.)

**Secure Services** As of TF-M 1.3.0, the following secure services are available:

- Audit Logging (Audit)
- Crypto (Crypto)
- Firmware Update (FWU)
- Initial Attestation (IAS)
- Secure Storage, which has two parts:
  - Internal Trusted Storage (ITS)
  - Protected Storage (PS)

A template also exists for creating your own custom services.

For full details on these services, and their exposed APIs, please consult the [TF-M Documentation](#).

**Key Management and Derivation** Key and secret management is a critical part of any secure device. You need to ensure that key material is available to regions that require it, but not to anything else, and that it is stored securely in a way that makes it difficult to tamper with or maliciously access.

The **Internal Trusted Storage** service in TF-M is used by the **PSA Crypto** service (which itself makes use of mbedtls) to store keys, and ensure that private keys are only ever accessible to the secure processing environment. Crypto operations that make use of key material, such as when signing payloads or when decrypting sensitive data, all take place via key handles. At no point should the key material ever be exposed to the NS environment.

One exception is that private keys can be provisioned into the secure processing environment as a one-way operation, such as during a factory provisioning process, but even this should be avoided where possible, and a request should be made to the SPE (via the PSA Crypto service) to generate a new private key itself, and the public key for that can be requested during provisioning and logged in the factory. This ensures the private key material is never exposed, or even known during the provisioning phase.

TF-M also makes extensive use of the **Hardware Unique Key (HUK)**, which every TF-M device must provide. This device-unique key is used by the **Protected Storage** service, for example, to encrypt

information stored in external memory. For example, this ensures that the contents of flash memory can't be decrypted if they are removed and placed on a new device, since each device has its own unique HUK used while encrypting the memory contents the first time.

HUKs provide an additional advantage for developers, in that they can be used to derive new keys, and the **derived keys** don't need to be stored since they can be regenerated from the HUK at startup, using an additional salt/seed value (depending on the key derivation algorithm used). This removes the storage issue and a frequent attack vector. The HUK itself is usually highly protected in secure devices, and inaccessible directly by users.

TFM\_CRYPTO\_ALG\_HUK\_DERIVATION identifies the default key derivation algorithm used if a software implementation is used. The current default algorithm is HKDF (RFC 5869) with a SHA-256 hash. Other hardware implementations may be available on some platforms.

**Non-Secure Processing Environment** Zephyr is used for the NSPE, using a board that is supported by TF-M where the `:kconfig: CONFIG_BUILD_WITH_TFM` flag has been enabled.

Generally, you simply need to select the \*\_ns variant of a valid target (for example mps2\_an521\_ns), which will configure your Zephyr application to run in the NSPE, correctly build and link it with the TF-M secure images, sign the secure and non-secure images, and merge the three binaries into a single `tfm_merged.hex` file. The `west flash` command will flash `tfm_merged.hex` by default in this configuration.

At present, Zephyr can not be configured to be used as the secure processing environment.

### 8.19.2 TF-M Requirements

The following are some of the boards that can be used with TF-M:

Board	NSPE board name
mps2_an521_board	mps2_an521_ns (qemu supported)
bl5340_dvk	bl5340_dvk_cpuapp_ns
lpcxpresso55s69	lpcxpresso55s69_ns
nrf9160dk_nrf9160	nrf9160dk_nrf9160_ns
nrf5340dk_nrf5340	nrf5340dk_nrf5340_cpuapp_ns
nucleo_l552ze_q_board	nucleo_l552ze_q_ns
stm32l562e_dk_board	stm32l562e_dk_ns
v2m_musca_b1_board	v2m_musca_b1_ns
v2m_musca_s1_board	v2m_musca_s1_ns

You can run `west boards -n _ns$` to search for non-secure variants of different board targets. To make sure TF-M is supported for a board in its output, check that `:kconfig: CONFIG_TRUSTED_EXECUTION_NONSECURE` is set to y in that board's default configuration.

### Software Requirements

The following Python modules are required when building TF-M binaries:

- cryptography
- pyasn1
- pyyaml
- cbor >= 1.0.0
- imgtool >= 1.6.0
- jinja2

- click

You can install them via:

```
$ pip3 install --user cryptography pyasn1 pyyaml cbor>=1.0.0 imgtool>=1.6.0
→jinja2 click
```

They are used by TF-M's signing utility to prepare firmware images for validation by the bootloader.

Part of the process of generating binaries for QEMU and merging signed secure and non-secure binaries on certain platforms also requires the use of the `srec_cat` utility.

This can be installed on Linux via:

```
$ sudo apt-get install srecord
```

And on OS X via:

```
$ brew install srecord
```

For Windows-based systems, please make sure you have a copy of the utility available on your system path. See, for example: [SRecord for Windows](#)

### 8.19.3 TF-M Build System

When building a valid `_ns` board target, TF-M will be built in the background, and linked with the Zephyr non-secure application. No knowledge of TF-M's build system is required in most cases, and the following will build a TF-M and Zephyr image pair, and run it in qemu with no additional steps required:

```
$ west build -p auto -t mps2_an521_ns samples/tfm_integration/psa_crypto/ -
→t run
```

The outputs and certain key steps in this build process are described here, however, since you will need to understand and interact with the outputs, and deal with signing the secure and non-secure images before deploying them.

#### Images Created by the TF-M Build

The TF-M build system creates the following executable files:

- `tfm_s` - the secure firmware
- `tfm_ns` - a nonsecure app which is discarded in favor of the Zephyr app
- `bl2` - mcuboot, if enabled

For each of these, it creates `.bin`, `.hex`, `.elf`, and `.axf` files.

The TF-M build system also creates signed variants of `tfm_s` and `tfm_ns`, and a file which combines them:

- `tfm_s_signed`
- `tfm_ns_signed`
- `tfm_s_ns_signed`

For each of these, only `.bin` files are created.

The Zephyr build system usually signs both `tfm_s` and the Zephyr ns app itself. See below for details.

The 'tfm' target contains properties for all these paths. For example, the following will resolve to `<path>/tfm_s.hex`:

```
$<TARGET_PROPERTY:tfm,TFM_S_HEX_FILE>
```

See the top level CMakeLists.txt file in the tfm module for an overview of all the properties.

## Signing Images

When `:kconfig:CONFIG_TFM_BL2` is set to y, TF-M uses a secure bootloader (BL2) and firmware images must be signed with a private key. The firmware image is validated by the bootloader during updates using the corresponding public key, which is stored inside the secure bootloader firmware image.

By default, `tfm/bl2/ext/mcuboot/root-rsa-3072.pem` is used to sign secure images, and `tfm/bl2/ext/mcuboot/root-rsa-3072_1.pem` is used to sign non-secure images. These default .pem keys can (and **should**) be overridden using the `:kconfig:CONFIG_TFM_KEY_FILE_S` and `:kconfig:CONFIG_TFM_KEY_FILE_NS` config flags.

To satisfy [PSA Certified Level 1](#) requirements, **You MUST replace the default .pem file with a new key pair!**

To generate a new public/private key pair, run the following commands:

```
$ imgtool keygen -k root-rsa-3072_s.pem -t rsa-3072
$ imgtool keygen -k root-rsa-3072_ns.pem -t rsa-3072
```

You can then place the new .pem files in an alternate location, such as your Zephyr application folder, and reference them in the `prj.conf` file via the `:kconfig:CONFIG_TFM_KEY_FILE_S` and `:kconfig:CONFIG_TFM_KEY_FILE_NS` config flags.

**Warning:** Be sure to keep your private key file in a safe, reliable location! If you lose this key file, you will be unable to sign any future firmware images, and it will no longer be possible to update your devices in the field!

After the built-in signing script has run, it creates a `tfm_merged.hex` file that contains all three binaries: `bl2`, `tfm_s`, and the `zephyr` app. This hex file can then be flashed to your development board or run in QEMU.

**Custom CMake arguments** When building a Zephyr application with TF-M it might be necessary to control the CMake arguments passed to the TF-M build.

Zephyr TF-M build offers several Kconfig options for controlling the build, but doesn't cover every CMake argument supported by the TF-M build system.

The `TFM_CMAKE_OPTIONS` property on the `zephyr_property_target` can be used to pass custom CMake arguments to the TF-M build system.

To pass the CMake argument `-DF00=bar` to the TF-M build system, place the following CMake snippet in your CMakeLists.txt file.

```
set_property(TARGET zephyr_property_target
             APPEND PROPERTY TFM_CMAKE_OPTIONS
             -DF00=bar
)
```

**Note:** The `TFM_CMAKE_OPTIONS` is a list so it is possible to append multiple options. Also CMake generator expressions are supported, such as `$<1:-DF00=bar>`

### 8.19.4 Trusted Firmware-M Integration

The Trusted Firmware-M (TF-M) section contains information about the integration between TF-M and Zephyr RTOS. Use this information to help understand how to integrate TF-M with Zephyr for Cortex-M platforms and make use of its secure run-time services in Zephyr applications.

#### Board Definitions

TF-M will be built for the secure processing environment along with Zephyr if the `:kconfig: `CONFIG_BUILD_WITH_TFM`` flag is set to `y`.

Generally, this value should never be set at the application level, however, and all config flags required for TF-M should be set in a board variant with the `_ns` suffix.

This board variant must define an appropriate flash, SRAM and peripheral configuration that takes into account the initialisation process in the secure processing environment. `:kconfig: `CONFIG_TFM_BOARD`` must also be set via `modules/trusted-firmware-m/Kconfig.tfm` to the board name that TF-M expects for this target, so that it knows which target to build for the secure processing environment.

**Example:** `mps2_an521_ns` The `mps2_an521` target is a dual-core Arm Cortex-M33 evaluation board that, when using the default board variant, would generate a secure Zephyr binary.

The optional `mps2_an521_ns` target, however, sets these additional kconfig flags that indicate that Zephyr should be built as a non-secure image, linked with TF-M as an external project, and optionally the secure bootloader:

- `:kconfig: `CONFIG_TRUSTED_EXECUTION_NONSECURE`` `y`
- `:kconfig: `CONFIG_ARM_TRUSTZONE_M`` `y`

Comparing the `mps2_an521.dts` and `mps2_an521_ns.dts` files, we can see that the `_ns` version defines offsets in flash and SRAM memory, which leave the required space for TF-M and the secure bootloader:

```
reserved-memory {
    #address-cells = <1>;
    #size-cells = <1>;
    ranges;

    /* The memory regions defined below must match what the TF-M
     * project has defined for that board - a single image boot is
     * assumed. Please see the memory layout in:
     * https://git.trustedfirmware.org/TF-M/trusted-firmware-m.git/tree/
     * platform/ext/target/mps2/an521/partition/flash_layout.h
     */

    code: memory@100000 {
        reg = <0x00100000 DT_SIZE_K(512)>;
    };

    ram: memory@28100000 {
        reg = <0x28100000 DT_SIZE_M(1)>;
    };
};
```

This reserves 1 MB of code memory and 1 MB of RAM for secure boot and TF-M, such that our non-secure Zephyr application code will start at 0x10000, with RAM at 0x28100000. 512 KB code memory is available for the NS zephyr image, along with 1 MB of RAM.

This matches the flash memory layout we see in `flash_layout.h` in TF-M:

```
* 0x0000_0000 BL2 - MCUBoot (0.5 MB)
* 0x0008_0000 Secure image      primary slot (0.5 MB)
* 0x0010_0000 Non-secure image primary slot (0.5 MB)
* 0x0018_0000 Secure image      secondary slot (0.5 MB)
* 0x0020_0000 Non-secure image secondary slot (0.5 MB)
* 0x0028_0000 Scratch area (0.5 MB)
* 0x0030_0000 Protected Storage Area (20 KB)
* 0x0030_5000 Internal Trusted Storage Area (16 KB)
* 0x0030_9000 NV counters area (4 KB)
* 0x0030_A000 Unused (984 KB)
```

mps2/an521 will be passed in to Tf-M as the board target, specified via `:kconfig: CONFIG_TFM_BOARD`.

## 8.20 West (Zephyr’s meta-tool)

The Zephyr project includes a swiss-army knife command line tool named `west`<sup>1</sup>. West is developed in its own [repository](#).

West’s built-in commands provide a multiple repository management system with features inspired by Google’s Repo tool and Git submodules. West is also “pluggable”: you can write your own west extension commands which add additional features to west. Zephyr uses this to provide conveniences for building applications, flashing and debugging them, and more.

Like git and docker, the top-level west command takes some common options, a sub-command to run, and then options and arguments for that sub-command:

```
west [common-opts] <command> [opts] <args>
```

Since west v0.8, you can also run west like this:

```
python3 -m west [common-opts] <command> [opts] <args>
```

You can run `west --help` (or `west -h` for short) to get top-level help for available west commands, and `west <command> -h` for detailed help on each command.

The following pages document west’s v0.11.x releases, and provide additional context about the tool.

### 8.20.1 Installing west

West is written in Python 3 and distributed through [PyPI](#). Use `pip3` to install or upgrade west:

On Linux:

```
pip3 install --user -U west
```

On Windows and macOS:

```
pip3 install -U west
```

---

**Note:** See [Python and pip](#) for additional clarification on using the `--user` switch.

---

Afterwards, you can run `pip3 show -f west` for information on where the west binary and related files were installed.

Once west is installed, you can use it to [clone the Zephyr repositories](#).

---

<sup>1</sup> Zephyr is an English name for the Latin [Zephyrus](#), the ancient Greek god of the west wind.

## Structure

West's code is distributed via PyPI in a Python package named `west`. This distribution includes a launcher executable, which is also named `west` (or `west.exe` on Windows).

When `west` is installed, the launcher is placed by `pip3` somewhere in the user's filesystem (exactly where depends on the operating system, but should be on the `PATH` [environment variable](#)). This launcher is the command-line entry point to running both built-in commands like `west init`, `west update`, along with any extensions discovered in the workspace.

In addition to its command-line interface, you can also use `west`'s Python APIs directly. See `west-apis` for details.

## Enabling shell completion

West currently supports shell completion in the following combinations of platform and shell:

- Linux: `bash`
- macOS: `bash`
- Windows: not available

In order to enable shell completion, you will need to obtain the corresponding completion script and have it sourced every time you enter a new shell session.

To obtain the completion script you can use the `west completion` command:

```
cd /path/to/zephyr/  
west completion bash > ~/west-completion.bash
```

---

**Note:** Remember to update your local copy of the completion script using `west completion` when you update Zephyr.

---

Next, you need to import `west-completion.bash` into your `bash` shell.

On Linux, you have the following options:

- Copy `west-completion.bash` to `/etc/bash_completion.d/`.
- Copy `west-completion.bash` to `/usr/share/bash-completion/completions/`.
- Copy `west-completion.bash` to a local folder and source it from your `~/.bashrc`.

On macOS, you have the following options:

- Copy `west-completion.bash` to a local folder and source it from your `~/.bash_profile`
- Install the `bash-completion` package with `brew`:

```
brew install bash-completion
```

then source the main `bash` completion script in your `~/.bash_profile`:

```
source /usr/local/etc/profile.d/bash_completion.sh
```

and finally copy `west-completion.bash` to `/usr/local/etc/bash_completion.d/`.

## 8.20.2 West Release Notes

### v0.11.1

#### New features:

- `west status` now only prints output for projects which have a nonempty status.

#### Bug fixes:

- The manifest file parser was incorrectly allowing project names which contain the path separator characters `/` and `\`. These invalid characters are now rejected.

Note: if you need to place a project within a subdirectory of the workspace `topdir`, use the `path:` key. If you need to customize a project's fetch URL relative to its remote `url-base:`, use `repo-path:.` See [Projects](#) for examples.

- The changes made in west v0.10.1 to the `west init --manifest-rev` option which selected the default branch name were leaving the manifest repository in a detached HEAD state. This has been fixed by using `git clone` internally instead of `git init` and `git fetch`. See [issue #522](#) for details.
- The `WEST_CONFIG_LOCAL` environment variable now correctly overrides the default location, `<workspace topdir>/.west/config`.
- `west update --fetch=smart` (`smart` is the default) now correctly skips fetches for project revisions which are [lightweight tags](#) (it already worked correctly for annotated tags; only lightweight tags were unnecessarily fetched).

#### Other changes:

- The fix for [issue #522](#) mentioned above introduces a new restriction. The `west init --manifest-rev` option value, if given, must now be either a branch or a tag. In particular, “pseudo-branches” like GitHub's `pull/1234/head` references which could previously be used to fetch a pull request can no longer be passed to `--manifest-rev`. Users must now fetch and check out such revisions manually after running `west init`.

#### API changes:

- `west.manifest.Manifest.get_projects()` avoids incorrect results in some edge cases described in [issue #523](#).
- `west.manifest.Project.sha()` now works correctly for tag revisions. (This applies to both lightweight and annotated tags.)

### v0.11.0

#### New features:

- `west update` now supports `--narrow`, `--name-cache`, and `--path-cache` options. These can be influenced by the `update.narrow`, `update.name-cache`, and `update.path-cache` [Configuration](#) options. These can be used to optimize the speed of the update.
- `west update` now supports a `--fetch-opt` option that will be passed to the `git fetch` command used to fetch remote revisions when updating each project.

#### Bug fixes:

- `west update` now synchronizes Git submodules in projects by default. This avoids issues if the URL changes in the manifest file from when the submodule was first initialized. This behavior can be disabled by setting the `update.sync-submodules` configuration option to `false`.

#### Other changes:

- the `west-apis-manifest` module has fixed docstrings for the `Project` class

### v0.10.1

New features:

- The `west init` command's `--manifest-rev` (`--mr`) option no longer defaults to `master`. Instead, the command will query the repository for its default branch name and use that instead. This allows users to move from `master` to `main` without breaking scripts that do not provide this option.

### v0.10.0

New features:

- The name key in a project's `submodules list` is now optional.

Bug fixes:

- West now checks that the manifest schema version is one of the explicitly allowed values documented in [Version](#). The old behavior was just to check that the schema version was newer than the west version where the `manifest: version:` key was introduced. This incorrectly allowed invalid schema versions, like `0.8.2`.

Other changes:

- A manifest file's `group-filter` is now propagated through an `import`. This is a change from how west v0.9.x handled this. In west v0.9.x, only the top level manifest file's `group-filter` had any effect; the group filter lists from any imported manifests were ignored.

Starting with west v0.10.0, the group filter lists from imported manifests are also imported. For details, see [Group Filters and Imports](#).

The new behavior will take effect if `manifest: version:` is not given or is at least `0.10`. The old behavior is still available in the top level manifest file only with an explicit `manifest: version: 0.9`. See [Version](#) for more information on schema versions.

See [west pull request #482](#) for the motivation for this change and additional context.

### v0.9.1

Bug fixes:

- Commands like `west manifest --resolve` now correctly include group and group filter information.

Other changes:

- West now warns if you combine `import` with `group-filter`. Semantics for this combination have changed starting with v0.10.x. See the v0.10.0 release notes above for more information.

### v0.9.0

**Warning:** The `west config` fix described below comes at a cost: any comments or other manual edits in configuration files will be removed when setting a configuration option via that command or the `west.configuration` API.

**Warning:** Combining the `group-filter` feature introduced in this release with manifest imports is discouraged. The resulting behavior has changed in west v0.10.

New features:

- West manifests now support [Git Submodules in Projects](#). This allows you to clone [Git submodules](#) into a west project repository in addition to the project repository itself.
  - West manifests now support [Project Groups and Active Projects](#). Project groups can be enabled and disabled to determine what projects are “active”, and therefore will be acted upon by the following commands: `west update`, `west list`, `west diff`, `west status`, `west forall`.
  - `west update` no longer updates inactive projects by default. It now supports a `--group-filter` option which allows for one-time modifications to the set of enabled and disabled project groups.
  - Running `west list`, `west diff`, `west status`, or `west forall` with no arguments does not print information for inactive projects by default. If the user specifies a list of projects explicitly at the command line, output for them is included regardless of whether they are active.
- These commands also now support `--all` arguments to include all projects, even inactive ones.
- `west list` now supports a `{groups}` format string key in its `--format` argument.

#### Bug fixes:

- The `west config` command and `west.configuration` API did not correctly store some configuration values, such as strings which contain commas. This has been fixed; see [commit 36f3f91e](#) for details.
- A manifest file with an empty `manifest: self: path: value` is invalid, but west used to let it pass silently. West now rejects such manifests.
- A bug affecting the behavior of the `west init -l .` command was fixed; see [issue #435](#).

#### API changes:

- added `west.manifest.Manifest.is_active()`
- added `west.manifest.Manifest.group_filter`
- added `submodules` attribute to `west.manifest.Project`, which has newly added type `west.manifest.Submodule`

#### Other changes:

- The [Manifest Imports](#) feature now supports the terms `allowlist` and `blocklist` instead of `whitelist` and `blacklist`, respectively.

The old terms are still supported for compatibility, but the documentation has been updated to use the new ones exclusively.

## v0.8.0

This is a feature release which changes the manifest schema by adding support for a `path-prefix:` key in an `import:` mapping, along with some other features and fixes.

- Manifest import mappings now support a `path-prefix:` key, which places the project and its imported repositories in a subdirectory of the workspace. See [Example 3.4: Import into a subdirectory](#) for an example.
- The west command line application can now also be run using `python3 -m west`. This makes it easier to run west under a particular Python interpreter without modifying the `PATH` environment variable.
- `west manifest -path` prints the absolute path to `west.yml`
- `west init` now supports an `--mf foo.yml` option, which initializes the workspace using `foo.yml` instead of `west.yml`.
- `west list` now prints the manifest repository’s path using the `manifest.path` [configuration option](#), which may differ from the `self: path: value` in the manifest data. The old behavior is still available, but requires passing a new `--manifest-path-from-yaml` option.

- Various Python API changes; see west-apis for details.

### v0.7.3

This is a bugfix release.

- Fix an error where a failed import could leave the workspace in an unusable state (see [PR #415](https://github.com/zephyrproject-rtos/west/pull/415) for details)

### v0.7.2

This is a bugfix and minor feature release.

- Filter out duplicate extension commands brought in by manifest imports
- Fix `west.Manifest.get_projects()` when finding the manifest repository by path

### v0.7.1

This is a bugfix and minor feature release.

- `west update --stats` now prints timing for operations which invoke a subprocess, time spent in west's Python process for each project, and total time updating each project.
- `west topdir` always prints a POSIX style path
- minor console output changes

### v0.7.0

The main user-visible feature in west 0.7 is the *Manifest Imports* feature. This allows users to load west manifest data from multiple different files, resolving the results into a single logical manifest.

Additional user-visible changes:

- The idea of a “west installation” has been renamed to “west workspace” in this documentation and in the west API documentation. The new term seems to be easier for most people to work with than the old one.
- West manifests now support a *schema version*.
- The “west config” command can now be run outside of a workspace, e.g. to run `west config --global section.key value` to set a configuration option's value globally.
- There is a new *west topdir* command, which prints the root directory of the current west workspace.
- The `west -vv init` command now prints the git operations being performed, and their results.
- The restriction that no project can be named “manifest” is now enforced; the name “manifest” is reserved for the manifest repository, and is usable as such in commands like `west list manifest`, instead of `west list path-to-manifest-repository` being the only way to say that
- It's no longer an error if there is no project named “zephyr”. This is part of an effort to make west generally usable for non-Zephyr use cases.
- Various bug fixes.

The developer-visible changes to the west-apis are:

- `west.build` and `west.cmake`: deprecated; this is Zephyr-specific functionality and should never have been part of west. Since Zephyr v1.14 LTS relies on it, it will continue to be included in the distribution, but will be removed when that version of Zephyr is obsoleted.

- `west.commands:`
  - `WestCommand.requires_installation:` deprecated; use `requires_workspace` instead
  - `WestCommand.requires_workspace:` new
  - `WestCommand.has_manifest:` new
  - `WestCommand.manifest:` this is now settable
- `west.configuration:` callers can now identify the workspace directory when reading and writing configuration files
- `west.log:`
  - `msg():` new
- `west.manifest:`
  - The module now uses the standard logging module instead of `west.log`
  - `QUAL_REFS_WEST:` new
  - `SCHEMA_VERSION:` new
  - Defaults: removed
  - `Manifest.as_dict():` new
  - `Manifest.as_frozen_yaml():` new
  - `Manifest.as_yaml():` new
  - `Manifest.from_file()` and `from_data():` these factory methods are more flexible to use and less reliant on global state
  - `Manifest.validate():` new
  - `ManifestImportFailed:` new
  - `ManifestProject:` semi-deprecated and will likely be removed later.
  - `Project:` the constructor now takes a `topdir` argument
  - `Project.format()` and its callers are removed. Use f-strings instead.
  - `Project.name_and_path:` new
  - `Project.remote_name:` new
  - `Project.sha()` now captures `stderr`
  - Remote: removed

West now requires Python 3.6 or later. Additionally, some features may rely on Python dictionaries being insertion-ordered; this is only an implementation detail in CPython 3.6, but is part of the language specification as of Python 3.7.

### v0.6.3

This point release fixes an error in the behavior of the deprecated `west.cmake` module.

### v0.6.2

This point release fixes an error in the behavior of `west update --fetch=smart`, introduced in v0.6.1. All v0.6.1 users must upgrade.

## v0.6.1

**Warning:** Do not use this point release. Make sure to use v0.6.2 instead.

The user-visible features in this point release are:

- The `west update` command has a new `--fetch` command line flag and `update.fetch` [configuration option](#). The default value, “smart”, skips fetching SHAs and tags which are available locally.
- Better and more consistent error-handling in the `west diff`, `west status`, `west forall`, and `west update` commands. Each of these commands can operate on multiple projects; if a subprocess related to one project fails, these commands now continue to operate on the rest of the projects. All of them also now report a nonzero error code from the west process if any of these subprocesses fails (this was previously not true of `west forall` in particular).
- The `west manifest` command also handles errors better.
- The `west list` command now works even when the projects are not cloned, as long as its format string only requires information which can be read from the manifest file. It still fails if the format string requires data stored in the project repository, e.g. if it includes the `{sha}` format string key.
- Commands and options which operate on git revisions now accept abbreviated SHAs. For example, `west init --mr SHA_PREFIX` now works. Previously, the `--mr` argument needed to be the entire 40 character SHA if it wasn't a branch or a tag.

The developer-visible changes to the west-apis are:

- `west.log.banner()`: new
- `west.log.small_banner()`: new
- `west.manifest.Manifest.get_projects()`: new
- `west.manifest.Project.is_cloned()`: new
- `west.commands.WestCommand` instances can now access the parsed `Manifest` object via a new `self.manifest` property during the `do_run()` call. If read, it returns the `Manifest` object or aborts the command if it could not be parsed.
- `west.manifest.Project.git()` now has a `capture_stderr` kwarg

## v0.6.0

- No separate bootstrapper

In west v0.5.x, the program was split into two components, a bootstrapper and a per-installation clone. See [Multiple Repository Management in the v1.14 documentation](#) for more details.

This is similar to how Google's Repo tool works, and lets west iterate quickly at first. It caused confusion, however, and west is now stable enough to be distributed entirely as one piece via PyPI.

From v0.6.x onwards, all of the core west commands and helper classes are part of the west package distributed via PyPI. This eliminates complexity and makes it possible to import west modules from anywhere in the system, not just extension commands.

- The `selfupdate` command still exists for backwards compatibility, but now simply exits after printing an error message.
- Manifest syntax changes
  - A west manifest file's `projects` elements can now specify their fetch URLs directly, like so:

```
manifest:
  projects:
    - name: example-project-name
      url: https://github.com/example/example-project
```

Project elements with `url` attributes set in this way may not also have `remote` attributes.

- Project names must be unique: this restriction is needed to support future work, but was not possible in west v0.5.x because distinct projects may have URLs with the same final pathname component, like so:

```
manifest:
  remotes:
    - name: remote-1
      url-base: https://github.com/remote-1
    - name: remote-2
      url-base: https://github.com/remote-2
  projects:
    - name: project
      remote: remote-1
      path: remote-1-project
    - name: project
      remote: remote-2
      path: remote-2-project
```

These manifests can now be written with projects that use `url` instead of `remote`, like so:

```
manifest:
  projects:
    - name: remote-1-project
      url: https://github.com/remote-1/project
    - name: remote-2-project
      url: https://github.com/remote-2/project
```

- The `west list` command now supports a `{sha}` format string key
- The default format string for `west list` was changed to `"{name:12} {path:28} {revision:40} {url}"`.
- The command `west manifest --validate` can now be run to load and validate the current manifest file, among other error-handling fixes related to manifest parsing.
- Incompatible API changes were made to west's APIs. Further changes are expected until API stability is declared in west v1.0.
  - The `west.manifest.Project` constructor's `remote` and `defaults` positional arguments are now kwargs. A new `url` kwarg was also added; if given, the `Project` URL is set to that value, and the `remote` kwarg is ignored.
  - `west.manifest.MANIFEST_SECTIONS` was removed. There is only one section now, namely `manifest`. The `sections` kwargs in the `west.manifest.Manifest` factory methods and constructor were also removed.
  - The `west.manifest.SpecialProject` class was removed. Use `west.manifest.ManifestProject` instead.

## v0.5.x

West v0.5.x is the first version used widely by the Zephyr Project as part of its v1.14 Long-Term Support (LTS) release. The [west v0.5.x documentation](#) is available as part of the Zephyr's v1.14 documentation.

West's main features in v0.5.x are:

- Multiple repository management using Git repositories, including self-update of west itself
- Hierarchical configuration files
- Extension commands

### Versions Before v0.5.x

Tags in the west repository before v0.5.x are prototypes which are of historical interest only.

## 8.20.3 Troubleshooting West

This page covers common issues with west and how to solve them.

### west update fetching failures

One good way to troubleshoot fetching issues is to run `west update` in verbose mode, like this:

```
west -v update
```

The output includes Git commands run by west and their outputs. Look for something like this:

```
=== updating your_project (path/to/your/project):  
west.manifest: your_project: checking if cloned  
[...other west.manifest logs...]  
--- your_project: fetching, need revision SOME_SHA  
west.manifest: running 'git fetch ... https://github.com/your-username/your_project ..  
↪ .' in /some/directory
```

The `git fetch` command example in the last line above is what needs to succeed.

One strategy is to go to `/some/directory`, copy/paste and run the entire `git fetch` command, then debug from there using the documentation for your credential storage helper.

If you're behind a corporate firewall and may have proxy or other issues, `curl -v FETCH_URL` (for HTTPS URLs) or `ssh -v FETCH_URL` (for SSH URLs) may be helpful.

If you can get the `git fetch` command to run successfully without prompting for a password when you run it directly, you will be able to run `west update` without entering your password in that same shell.

### “west’ is not recognized as an internal or external command, operable program or batch file.’

On Windows, this means that either west is not installed, or your PATH environment variable does not contain the directory where pip installed `west.exe`.

First, make sure you've installed west; see [Installing west](#). Then try running `west` from a new `cmd.exe` window. If that still doesn't work, keep reading.

You need to find the directory containing `west.exe`, then add it to your PATH. (This PATH change should have been done for you when you installed Python and pip, so ordinarily you should not need to follow these steps.)

Run this command in `cmd.exe`:

```
pip3 show west
```

Then:

1. Look for a line in the output that looks like `Location: C:\foo\python\python38\lib\site-packages`. The exact location will be different on your computer.
2. Look for a file named `west.exe` in the `scripts` directory `C:\foo\python\python38\scripts`.

---

**Important:** Notice how `lib\site-packages` in the `pip3 show` output was changed to `scripts`!

---

3. If you see `west.exe` in the `scripts` directory, add the full path to `scripts` to your `PATH` using a command like this:

```
setx PATH "%PATH%;C:\foo\python\python38\scripts"
```

**Do not just copy/paste this command.** The `scripts` directory location will be different on your system.

4. Close your `cmd.exe` window and open a new one. You should be able to run `west`.

### “Error: unexpected keyword argument ‘requires\_workspace’”

This error occurs on some Linux distributions after upgrading to `west` 0.7.0 or later from 0.6.x. For example:

```
$ west update
[... stack trace ...]
TypeError: __init__() got an unexpected keyword argument 'requires_workspace'
```

This appears to be a problem with the distribution’s `pip`; see [this comment in west issue 373](#) for details. Some versions of **Ubuntu** and **Linux Mint** are known to have this problem. Some users report issues on Fedora as well.

Neither macOS nor Windows users have reported this issue. There have been no reports of this issue on other Linux distributions, like Arch Linux, either.

**Workaround 1:** remove the old version, then upgrade:

```
$ pip3 show west | grep Location: | cut -f 2 -d ' '
/home/foo/.local/lib/python3.6/site-packages
$ rm -r /home/foo/.local/lib/python3.6/site-packages/west
$ pip3 install --user west==0.7.0
```

**Workaround 2:** install `west` in a Python virtual environment

One option is to use the [venv module](#) that’s part of the Python 3 standard library. Some distributions remove this module from their base Python 3 packages, so you may need to do some additional work to get it installed on your system.

### “invalid choice: ‘build’” (or ‘flash’, etc.)

If you see an unexpected error like this when trying to run a Zephyr extension command (like [west flash](#), [west build](#), etc.):

```
$ west build [...]
west: error: argument <command>: invalid choice: 'build' (choose from 'init', [...])

$ west flash [...]
west: error: argument <command>: invalid choice: 'flash' (choose from 'init', [...])
```

The most likely cause is that you’re running the command outside of a *west workspace*. West needs to know where your workspace is to find *Extensions*.

To fix this, you have two choices:

1. Run the command from inside a workspace (e.g. the `zephyrproject` directory you created when you *got started*).

For example, create your build directory inside the workspace, or run `west flash --build-dir YOUR_BUILD_DIR` from inside the workspace.

2. Set the `ZEPHYR_BASE` *environment variable* and re-run the west extension command. If set, west will use `ZEPHYR_BASE` to find your workspace.

If you’re unsure whether a command is built-in or an extension, run `west help` from inside your workspace. The output prints extension commands separately, and looks like this for mainline Zephyr:

```
$ west help

built-in commands for managing git repositories:
  init:                create a west workspace
  [...]

other built-in commands:
  help:                get help for west or a command
  [...]

extension commands from project manifest (path: zephyr):
  build:               compile a Zephyr application
  flash:               flash and run a binary on a board
  [...]
```

### “invalid choice: ‘post-init’”

If you see this error when running `west init`:

```
west: error: argument <command>: invalid choice: 'post-init'
(choose from 'init', 'update', 'list', 'manifest', 'diff',
'status', 'forall', 'config', 'selfupdate', 'help')
```

Then you have an old version of west installed, and are trying to use it in a workspace that requires a more recent version.

The easiest way to resolve this issue is to upgrade west and retry as follows:

1. Install the latest west with the `-U` option for `pip3 install` as shown in *Installing west*.
2. Back up any contents of `zephyrproject/.west/config` that you want to save. (If you don’t have any configuration options set, it’s safe to skip this step.)
3. Completely remove the `zephyrproject/.west` directory (if you don’t, you will get the “already in a workspace” error message discussed next).
4. Run `west init` again.

### “already in an installation”

You may see this error when running `west init` with west 0.6:

```
FATAL ERROR: already in an installation (<some directory>), aborting
```

If this is unexpected and you're really trying to create a new west workspace, then it's likely that west is using the ZEPHYR\_BASE [environment variable](#) to locate a workspace elsewhere on your system.

This is intentional; it allows you to put your Zephyr applications in any directory and still use west to build, flash, and debug them, for example.

To resolve this issue, unset ZEPHYR\_BASE and try again.

## 8.20.4 Basics

This page introduces west's basic concepts and provides references to further reading.

West's built-in commands allow you to work with *projects* (Git repositories) under a common *workspace* directory.

### Example workspace

If you've followed the upstream Zephyr getting started guide, your workspace looks like this:

```

zephyrproject/           # west topdir
├── .west/                # marks the location of the topdir
│   └── config             # per-workspace local configuration file
│
│   # The manifest repository, never modified by west after creation:
├── zephyr/               # .git/ repo
│   ├── west.yml           # manifest file
│   └── [... other files ...]
│
│   # Projects managed by west:
├── modules/
│   └── lib/
│       └── tinycbor/       # .git/ project
├── net-tools/            # .git/ project
└── [... other projects ...]
```

### Workspace concepts

Here are the basic concepts you should understand about this structure. Additional details are in [Workspaces](#).

**topdir** Above, zephyrproject is the name of the workspace's top level directory, or *topdir*. (The name zephyrproject is just an example – it could be anything, like z, my-zephyr-workspace, etc.)

You'll typically create the topdir and a few other files and directories using [west init](#).

**.west directory** The topdir contains the .west directory. When west needs to find the topdir, it searches for .west, and uses its parent directory. The search starts from the current working directory (and starts again from the location in the ZEPHYR\_BASE environment variable as a fallback if that fails).

**configuration file** The file .west/config is the workspace's [local configuration file](#).

**manifest repository** Every west workspace contains exactly one *manifest repository*, which is a Git repository containing a *manifest file*. The location of the manifest repository is given by the [manifest.path configuration option](#) in the local configuration file.

For upstream Zephyr, zephyr is the manifest repository, but you can configure west to use any Git repository in the workspace as the manifest repository. The only requirement is that it contains a valid manifest file. See [Topologies supported](#) for information on other options, and [West Manifests](#) for details on the manifest file format.

**manifest file** The manifest file is a YAML file that defines *projects*, which are the additional Git repositories in the workspace managed by west. The manifest file is named `west.yml` by default; this can be overridden using the `manifest.file` local configuration option.

You use the [west update](#) command to update the workspace's projects based on the contents of the manifest file.

**projects** Projects are Git repositories managed by west. Projects are defined in the manifest file and can be located anywhere inside the workspace. In the above example workspace, `tinycbor` and `net-tools` are projects.

By default, the Zephyr [build system](#) uses west to get the locations of all the projects in the workspace, so any code they contain can be used as [Modules \(External projects\)](#).

**extensions** Any repository known to west (either the manifest repository or any project repository) can define [Extensions](#). Extensions are extra west commands you can run when using that workspace.

The zephyr repository uses this feature to provide Zephyr-specific commands like [west build](#). Defining these as extensions keeps west's core agnostic to the specifics of any workspace's Zephyr version, etc.

**ignored files** A workspace can contain additional Git repositories or other files and directories not managed by west. West basically ignores anything in the workspace except `.west`, the manifest repository, and the projects specified in the manifest file.

## west init and west update

The two most important workspace-related commands are `west init` and `west update`.

`west init` **basics** This command creates a west workspace.

---

**Important:** West doesn't change your manifest repository contents after `west init` is run. Use ordinary Git commands to pull new versions, etc.

---

You will typically run it once, like this:

```
west init -m https://github.com/zephyrproject-rtos/zephyr --mr v2.5.0 zephyrproject
```

This will:

1. Create the `topdir`, `zephyrproject`, along with `.west` and `.west/config` inside it
2. Clone the manifest repository from <https://github.com/zephyrproject-rtos/zephyr>, placing it into `zephyrproject/zephyr`
3. Check out the `v2.5.0` git tag in your local zephyr clone
4. Set `manifest.path` to `zephyr` in `.west/config`
5. Set `manifest.file` to `west.yml`

Your workspace is now almost ready to use; you just need to run `west update` to clone the rest of the projects into the workspace to finish.

For more details, see [west init](#).

`west update` **basics** This command makes sure your workspace contains Git repositories matching the projects in the manifest file.

---

**Important:** Whenever you check out a different revision in your manifest repository, you should run `west update` to make sure your workspace contains the project repositories the new revision expects.

---

The `west update` command reads the manifest file's contents by:

1. Finding the topdir. In the `west init` example above, that means finding `zephyrproject`.
2. Loading `.west/config` in the topdir to read the `manifest.path` (e.g. `zephyr`) and `manifest.file` (e.g. `west.yml`) options.
3. Loading the manifest file given by these options (e.g. `zephyrproject/zephyr/west.yml`).

It then uses the manifest file to decide where missing projects should be placed within the workspace, what URLs to clone them from, and what Git revisions should be checked out locally. Project repositories which already exist are updated in place by fetching and checking out their respective Git revisions in the manifest file.

For more details, see [west update](#).

## Other built-in commands

See [Built-in commands](#).

## Zephyr Extensions

See the following pages for information on Zephyr's extension commands:

- [Building, Flashing and Debugging](#)
- [Signing Binaries](#)
- [Additional Zephyr extension commands](#)
- [Enabling shell completion](#)

## Troubleshooting

See [Troubleshooting West](#).

### 8.20.5 Built-in commands

This page describes `west`'s built-in commands, some of which were introduced in [Basics](#), in more detail.

Some commands are related to Git commands with the same name, but operate on the entire workspace. For example, `west diff` shows local changes in multiple Git repositories in the workspace.

Some commands take projects as arguments. These arguments can be project names as specified in the manifest file, or (as a fallback) paths to them on the local file system. Omitting project arguments to commands which accept them (such as `west list`, `west forall`, etc.) usually defaults to using all projects in the manifest file plus the manifest repository itself.

For additional help, run `west <command> -h` (e.g. `west init -h`).

## west init

This command creates a west workspace. It can be used in two ways:

1. Cloning a new manifest repository from a remote URL
2. Creating a workspace around an existing local manifest repository

**Option 1:** to clone a new manifest repository from a remote URL, use:

```
west init [-m URL] [--mr REVISION] [--mf FILE] [directory]
```

The new workspace is created in the given directory, creating a new `.west` inside this directory. You can give the manifest URL using the `-m` switch, the initial revision to check out using `--mr`, and the location of the manifest file within the repository using `--mf`.

For example, running:

```
west init -m https://github.com/zephyrproject-rtos/zephyr --mr v1.14.0 zp
```

would clone the upstream official zephyr repository into `zp/zephyr`, and check out the `v1.14.0` release. This command creates `zp/.west`, and set the `manifest.path` [configuration option](#) to `zephyr` to record the location of the manifest repository in the workspace. The default manifest file location is used.

The `-m` option defaults to `https://github.com/zephyrproject-rtos/zephyr`. The `--mf` option defaults to `west.yml`. Since west v0.10.1, west will use the default branch in the manifest repository unless the `--mr` option is used to override it. (In prior versions, `--mr` defaulted to `master`.)

If no directory is given, the current working directory is used.

**Option 2:** to create a workspace around an existing local manifest repository, use:

```
west init -l [--mf FILE] directory
```

This creates `.west` **next to** `directory` in the file system, and sets `manifest.path` to `directory`.

As above, `--mf` defaults to `west.yml`.

### Reconfiguring the workspace:

If you change your mind later, you are free to change `manifest.path` and `manifest.file` using [west config](#) after running `west init`. Just be sure to run `west update` afterwards to update your workspace to match the new manifest file.

## west update

```
west update [-f {always,smart}] [-k] [-r]
            [--group-filter FILTER] [--stats] [PROJECT ...]
```

### Which projects are updated:

By default, this command parses the manifest file, usually `west.yml`, and updates each project specified there. If your manifest uses [project groups](#), then only the active projects are updated.

To operate on a subset of projects only, give `PROJECT` argument(s). Each `PROJECT` is either a project name as given in the manifest file, or a path that points to the project within the workspace. If you specify projects explicitly, they are updated regardless of whether they are active.

### Project update procedure:

For each project that is updated, this command:

1. Initializes a local Git repository for the project in the workspace, if it does not already exist
2. Inspects the project's revision field in the manifest, and fetches it from the remote if it is not already available locally

3. Sets the project's `manifest-rev` branch to the commit specified by the revision in the previous step
4. Checks out `manifest-rev` in the local working copy as a `detached HEAD`
5. If the manifest file specifies a `submodules` key for the project, recursively updates the project's submodules as described below.

To avoid unnecessary fetches, `west update` will not fetch project revision values which are Git SHAs or tags that are already available locally. This is the behavior when the `-f` (`--fetch`) option has its default value, `smart`. To force this command to fetch from project remotes even if the revisions appear to be available locally, either use `-f always` or set the `update.fetch` [configuration option](#) to `always`. SHAs may be given as unique prefixes as long as they are acceptable to Git<sup>1</sup>.

If the project revision is a Git ref that is neither a tag nor a SHA (i.e. if the project is tracking a branch), `west update` always fetches, regardless of `-f` and `update.fetch`.

Some branch names might look like short SHAs, like `deadbeef`. West treats these like SHAs. You can disambiguate by prefixing the revision value with `refs/heads/`, e.g. `revision: refs/heads/deadbeef`.

For safety, `west update` uses `git checkout --detach` to check out a detached HEAD at the manifest revision for each updated project, leaving behind any branches which were already checked out. This is typically a safe operation that will not modify any of your local branches.

However, if you had added some local commits onto a previously detached HEAD checked out by `west`, then `git` will warn you that you've left behind some commits which are no longer referred to by any branch. These may be garbage-collected and lost at some point in the future. To avoid this if you have local commits in the project, make sure you have a local branch checked out before running `west update`.

If you would rather rebase any locally checked out branches instead, use the `-r` (`--rebase`) option.

If you would like `west update` to keep local branches checked out as long as they point to commits that are descendants of the new `manifest-rev`, use the `-k` (`--keep-descendants`) option.

---

**Note:** `west update --rebase` will fail in projects that have git conflicts between your branch and new commits brought in by the manifest. You should immediately resolve these conflicts as you usually do with `git`, or you can use `git -C <project_path> rebase --abort` to ignore incoming changes for the moment.

With a clean working tree, a plain `west update` never fails because it does not try to hold on to your commits and simply leaves them aside.

`west update --keep-descendants` offers an intermediate option that never fails either but does not treat all projects the same:

- in projects where your branch diverged from the incoming commits, it does not even try to rebase and leaves your branches behind just like a plain `west update` does;
  - in all other projects where no rebase or merge is needed it keeps your branches in place.
- 

### One-time project group manipulation:

The `--group-filter` option can be used to change which project groups are enabled or disabled for the duration of a single `west update` command. See [Project Groups and Active Projects](#) for details on the project group feature.

The `west update` command behaves as if the `--group-filter` option's value were appended to the `manifest.group-filter` [configuration option](#).

For example, running `west update --group-filter=+foo,-bar` would behave the same way as if you had temporarily appended the string `" +foo,-bar"` to the value of `manifest.group-filter`, run `west update`, then restored `manifest.group-filter` to its original value.

---

<sup>1</sup> West may fetch all refs from the Git server when given a SHA as a revision. This is because some Git servers have historically not allowed fetching SHAs directly.

Note that using the syntax `--group-filter=VALUE` instead of `--group-filter VALUE` avoids issues parsing command line options if you just want to disable a single group, e.g. `--group-filter=-bar`.

### Submodule update procedure:

If a project in the manifest has a `submodules` key, the submodules are updated as follows, depending on the value of the `submodules` key.

If the project has `submodules: true`, west first synchronizes the project's submodules with:

```
git submodule sync --recursive
```

West then runs one of the following in the project repository, depending on whether you run `west update` with the `--rebase` option or without it:

```
# without --rebase, e.g. "west update":
git submodule update --init --checkout --recursive

# with --rebase, e.g. "west update --rebase":
git submodule update --init --rebase --recursive
```

Otherwise, the project has `submodules: <list-of-submodules>`. In this case, west synchronizes the project's submodules with:

```
git submodule sync --recursive -- <submodule-path>
```

Then it updates each submodule in the list as follows, depending on whether you run `west update` with the `--rebase` option or without it:

```
# without --rebase, e.g. "west update":
git submodule update --init --checkout --recursive <submodule-path>

# with --rebase, e.g. "west update --rebase":
git submodule update --init --rebase --recursive <submodule-path>
```

The `git submodule sync` commands are skipped if the `update.sync-submodules` [Configuration](#) option is false.

### Other project commands

West has a few more commands for managing the projects in the workspace, which are summarized here. Run `west <command> -h` for detailed help.

- `west list`: print a line of information about each project in the manifest, according to a format string
- `west manifest`: manage the manifest file. See [Manifest Command](#).
- `west diff`: run `git diff` in local project repositories
- `west status`: run `git status` in local project repositories
- `west forall`: run an arbitrary command in local project repositories

### Other built-in commands

Finally, here is a summary of other built-in commands.

- `west config`: get or set [configuration options](#)
- `west topdir`: print the top level directory of the west workspace

- `west help`: get help about a command, or print information about all commands in the workspace, including [Extensions](#)

## 8.20.6 Workspaces

This page describes the *west workspace* concept introduced in [Basics](#) in more detail.

### The `manifest-rev` branch

West creates and controls a Git branch named `manifest-rev` in each project. This branch points to the revision that the manifest file specified for the project at the time `west update` was last run. Other workspace management commands may use `manifest-rev` as a reference point for the upstream revision as of this latest update. Among other purposes, the `manifest-rev` branch allows the manifest file to use SHAs as project revisions.

Although `manifest-rev` is a normal Git branch, west will recreate and/or reset it on the next update. For this reason, it is **dangerous** to check it out or otherwise modify it yourself. For instance, any commits you manually add to this branch may be lost the next time you run `west update`. Instead, check out a local branch with another name, and either rebase it on top of a new `manifest-rev`, or merge `manifest-rev` into it.

---

**Note:** West does not create a `manifest-rev` branch in the manifest repository, since west does not manage the manifest repository's branches or revisions.

---

### The `refs/west/*` Git refs

West also reserves all Git refs that begin with `refs/west/` (such as `refs/west/foo`) for itself in local project repositories. Unlike `manifest-rev`, these refs are not regular branches. West's behavior here is an implementation detail; users should not rely on these refs' existence or behavior.

### Private repositories

You can use west to fetch from private repositories. There is nothing west-specific about this.

The `west update` command essentially runs `git fetch YOUR_PROJECT_URL` when a project's `manifest-rev` branch must be updated to a newly fetched commit. It's up to your environment to make sure the fetch succeeds.

You can either enter the password manually or use any of the [credential helpers built in to Git](#). Since Git has credential storage built in, there is no need for a west-specific feature.

The following sections cover common cases for running `west update` without having to enter your password, as well as how to troubleshoot issues.

**Fetching via HTTPS** On Windows when fetching from GitHub, recent versions of Git prompt you for your GitHub password in a graphical window once, then store it for future use (in a default installation). Passwordless fetching from GitHub should therefore work “out of the box” on Windows after you have done it once.

In general, you can store your credentials on disk using the “store” git credential helper. See the [git-credential-store](#) manual page for details.

To use this helper for all the repositories in your workspace, run:

```
west forall -c "git config credential.helper store"
```

To use this helper on just the projects `foo` and `bar`, run:

```
west forall -c "git config credential.helper store" foo bar
```

To use this helper by default on your computer, run:

```
git config --global credential.helper store
```

On GitHub, you can set up a [personal access token](#) to use in place of your account password. (This may be required if your account has two-factor authentication enabled, and may be preferable to storing your account password in plain text even if two-factor authentication is disabled.)

If you don't want to store any credentials on the file system, you can store them in memory temporarily using [git-credential-cache](#) instead.

**Fetching via SSH** If your SSH key has no password, fetching should just work. If it does have a password, you can avoid entering it manually every time using [ssh-agent](#).

On GitHub, see [Connecting to GitHub with SSH](#) for details on configuration and key creation.

## Project locations

Projects can be located anywhere inside the workspace, but they may not “escape” it.

In other words, project repositories need not be located in subdirectories of the manifest repository or as immediate subdirectories of the `topdir`. However, projects must have paths inside the workspace.

You may replace a project's repository directory within the workspace with a symbolic link to elsewhere on your computer, but `west` will not do this for you.

## Topologies supported

The following are example source code topologies supported by `west`.

- T1: star topology, `zephyr` is the manifest repository
- T2: star topology, a Zephyr application is the manifest repository
- T3: forest topology, freestanding manifest repository

### T1: Star topology, `zephyr` is the manifest repository

- The `zephyr` repository acts as the central repository and specifies its [Modules \(External projects\)](#) in its `west.yml`
- Analogy with existing mechanisms: Git submodules with `zephyr` as the super-project

This is the default. See [Workspace concepts](#) for how mainline Zephyr is an example of this topology.

### T2: Star topology, application is the manifest repository

- Useful for those focused on a single application
- A repository containing a Zephyr application acts as the central repository and names other projects required to build it in its `west.yml`. This includes the `zephyr` repository and any modules.
- Analogy with existing mechanisms: Git submodules with the application as the super-project, `zephyr` and other projects as submodules

A workspace using this topology looks like this:

```

west-workspace/
├── application/           # .git/
│   ├── CMakeLists.txt
│   ├── prj.conf          never modified by west
│   ├── src/
│   │   └── main.c
│   └── west.yml          # main manifest with optional import(s) and override(s)
├── modules/
│   └── lib/
│       └── tinycbor/     # .git/ project from either the main manifest or some import.
└── zephyr/              # .git/ project
    └── west.yml          # This can be partially imported with lower precedence or
                           ↳ ignored.
                           # Only the 'manifest-rev' version can be imported.

```

Here is an example `application/west.yml` which uses [Manifest Imports](#), available since west 0.7, to import Zephyr v2.5.0 and its modules into the application manifest file:

```

# Example T2 west.yml, using manifest imports.
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v2.5.0
      import: true
  self:
    path: application

```

You can still selectively “override” individual Zephyr modules if you use `import:` in this way; see [Example 1.3: Downstream of a Zephyr release, with module fork](#) for an example.

Another way to do the same thing is to copy/paste `zephyr/west.yml` to `application/west.yml`, adding an entry for the zephyr project itself, like this:

```

# Equivalent to the above, but with manually maintained Zephyr modules.
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  defaults:
    remote: zephyrproject-rtos
  projects:
    - name: zephyr
      revision: v2.5.0
      west-commands: scripts/west-commands.yml
    - name: net-tools
      revision: some-sha-goes-here
      path: tools/net-tools
      # ... other Zephyr modules go here ...
  self:
    path: application

```

(The `west`-commands is there for *Building, Flashing and Debugging* and other Zephyr-specific *Extensions*. It's not necessary when using `import`.)

The main advantage to using `import` is not having to track the revisions of imported projects separately. In the above example, using `import` means Zephyr's *module* versions are automatically determined from the `zephyr/west.yml` revision, instead of having to be copy/pasted (and maintained) on their own.

### T3: Forest topology

- Useful for those supporting multiple independent applications or downstream distributions with no “central” repository
- A dedicated manifest repository which contains no Zephyr source code, and specifies a list of projects all at the same “level”
- Analogy with existing mechanisms: Google repo-based source distribution

A workspace using this topology looks like this:

```
west-workspace/
├── app1/                # .git/ project
│   ├── CMakeLists.txt
│   ├── prj.conf
│   └── src/
│       └── main.c
├── app2/                # .git/ project
│   ├── CMakeLists.txt
│   ├── prj.conf
│   └── src/
│       └── main.c
├── manifest-repo/      # .git/ never modified by west
│   └── west.yml         # main manifest with optional import(s) and override(s)
├── modules/
│   └── lib/
│       └── tynycbor/    # .git/ project from either the main manifest or
                        # from some import
└── zephyr/             # .git/ project
    └── west.yml         # This can be partially imported with lower precedence or
                        ↪ ignored.
                        # Only the 'manifest-rev' version can be imported.
```

Here is an example T3 `manifest-repo/west.yml` which uses *Manifest Imports*, available since `west` 0.7, to import Zephyr v2.5.0 and its modules, then add the `app1` and `app2` projects:

```
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
    - name: your-git-server
      url-base: https://git.example.com/your-company
  defaults:
    remote: your-git-server
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v2.5.0
      import: true
    - name: app1
      revision: SOME_SHA_OR_BRANCH_OR_TAG
```

(continues on next page)

(continued from previous page)

```

- name: app2
  revision: ANOTHER_SHA_OR_BRANCH_OR_TAG
self:
  path: manifest-repo

```

You can also do this “by hand” by copy/pasting `zephyr/west.yml` as shown [above](#) for the T2 topology, with the same caveats.

## 8.20.7 West Manifests

This page contains detailed information about west’s multiple repository model, manifest files, and the `west manifest` command. For API documentation on the `west.manifest` module, see `west-apis-manifest`. For a more general introduction and command overview, see [Basics](#).

### Multiple Repository Model

West’s view of the repositories in a west workspace, and their history, looks like the following figure (though some parts of this example are specific to upstream Zephyr’s use of west):

Fig. 13: West multi-repo history

The history of the manifest repository is the line of Git commits which is “floating” on top of the gray plane. Parent commits point to child commits using solid arrows. The plane below contains the Git commit history of the repositories in the workspace, with each project repository boxed in by a rectangle. Parent/child commit relationships in each repository are also shown with solid arrows.

The commits in the manifest repository (again, for upstream Zephyr this is the `zephyr` repository itself) each have a manifest file. The manifest file in each commit specifies the corresponding commits which it expects in each of the project repositories. This relationship is shown using dotted line arrows in the diagram. Each dotted line arrow points from a commit in the manifest repository to a corresponding commit in a project repository.

Notice the following important details:

- Projects can be added (like P1 between manifest repository commits D and E) and removed (P2 between the same manifest repository commits)
- Project and manifest repository histories don't have to move forwards or backwards together:
  - P2 stays the same from A → B, as do P1 and P3 from F → G.
  - P3 moves forward from A → B.
  - P3 moves backward from C → D.

One use for moving backward in project history is to “revert” a regression by going back to a revision before it was introduced.

- Project repository commits can be “skipped”: P3 moves forward multiple commits in its history from B → C.
- In the above diagram, no project repository has two revisions “at the same time”: every manifest file refers to exactly one commit in the projects it cares about. This can be relaxed by using a branch name as a manifest revision, at the cost of being able to bisect manifest repository history.

## Manifest Files

West manifests are YAML files. Manifests have a top-level `manifest` section with some subsections, like this:

```
manifest:
  remotes:
    # short names for project URLs
  projects:
    # a list of projects managed by west
  defaults:
    # default project attributes
  self:
    # configuration related to the manifest repository itself,
    # i.e. the repository containing west.yml
  version: "<schema-version>"
  group-filter:
    # a list of project groups to enable or disable
```

In YAML terms, the manifest file contains a mapping, with a `manifest` key. Any other keys and their contents are ignored (west v0.5 also required a `west` key, but this is ignored starting with v0.6).

The manifest contains subsections, like `defaults`, `remotes`, `projects`, and `self`. In YAML terms, the value of the `manifest` key is also a mapping, with these “subsections” as keys. As of west v0.10, all of these “subsection” keys are optional.

The `projects` value is a list of repositories managed by west and associated metadata. We'll discuss it soon, but first we will describe the `remotes` section, which can be used to save typing in the `projects` list.

**Remotes** The `remotes` subsection contains a sequence which specifies the base URLs where projects can be fetched from.

Each `remotes` element has a name and a “URL base”. These are used to form the complete Git fetch URL for each project. A project's fetch URL can be set by appending a project-specific path onto a remote URL base. (As we'll see below, projects can also specify their complete fetch URLs.)

For example:

```
manifest:
# ...
remotes:
- name: remote1
  url-base: https://git.example.com/base1
- name: remote2
  url-base: https://git.example.com/base2
```

The remotes keys and their usage are in the following table.

Table 16: remotes keys

Key	Description
name	Mandatory; a unique name for the remote.
url-base	A prefix that is prepended to the fetch URL for each project with this remote.

Above, two remotes are given, with names `remote1` and `remote2`. Their URL bases are respectively `https://git.example.com/base1` and `https://git.example.com/base2`. You can use SSH URL bases as well; for example, you might use `git@example.com:base1` if `remote1` supported Git over SSH as well. Anything acceptable to Git will work.

**Projects** The `projects` subsection contains a sequence describing the project repositories in the west workspace. Every project has a unique name. You can specify what Git remote URLs to use when cloning and fetching the projects, what revisions to track, and where the project should be stored on the local file system.

Here is an example. We'll assume the `remotes` given above.

```
manifest:
# [... same remotes as above...]
projects:
- name: proj1
  remote: remote1
  path: extra/project-1
- name: proj2
  repo-path: my-path
  remote: remote2
  revision: v1.3
- name: proj3
  url: https://github.com/user/project-three
  revision: abcde413a111
```

In this manifest:

- `proj1` has remote `remote1`, so its Git fetch URL is `https://git.example.com/base1/proj1`. The remote `url-base` is appended with a `/` and the project name to form the URL.

Locally, this project will be cloned at path `extra/project-1` relative to the west workspace's root directory, since it has an explicit `path` attribute with this value.

Since the project has no revision specified, `master` is used by default. The current tip of this branch will be fetched and checked out as a detached HEAD when west next updates this project.

- `proj2` has a remote and a `repo-path`, so its fetch URL is `https://git.example.com/base2/my-path`. The `repo-path` attribute, if present, overrides the default name when forming the fetch URL.

Since the project has no `path` attribute, its name is used by default. It will be cloned into a directory named `proj2`. The commit pointed to by the `v1.3` tag will be checked out when west updates the project.

- proj3 has an explicit url, so it will be fetched from `https://github.com/user/project-three`.

Its local path defaults to its name, proj3. Commit abcde413a111 will be checked out when it is next updated.

The available project keys and their usage are in the following table. Sometimes we'll refer to the defaults subsection; it will be described next.

Table 17: projects elements keys

Key(s)	Description
name	Mandatory; a unique name for the project. The name cannot be one of the reserved values “west” or “manifest”. The name must be unique in the manifest file.
remote, url	Mandatory (one of the two, but not both). If the project has a remote, that remote's url-base will be combined with the project's name (or repo-path, if it has one) to form the fetch URL instead. If the project has a url, that's the complete fetch URL for the remote Git repository. If the project has neither, the defaults section must specify a remote, which will be used as the the project's remote. Otherwise, the manifest is invalid.
repo-path	Optional. If given, this is concatenated on to the remote's url-base instead of the project's name to form its fetch URL. Projects may not have both url and repo-path attributes.
revision	Optional. The Git revision that west update should check out. This will be checked out as a detached HEAD by default, to avoid conflicting with local branch names. If not given, the revision value from the defaults subsection will be used if present. A project revision can be a branch, tag, or SHA. The default revision is master if not otherwise specified.
path	Optional. Relative path specifying where to clone the repository locally, relative to the top directory in the west workspace. If missing, the project's name is used as a directory name.
clone-depth	Optional. If given, a positive integer which creates a shallow history in the cloned repository limited to the given number of commits. This can only be used if the revision is a branch or tag.
west-commands	Optional. If given, a relative path to a YAML file within the project which describes additional west commands provided by that project. This file is named west-commands.yml by convention. See <a href="#">Extensions</a> for details.
import	Optional. If true, imports projects from manifest files in the given repository into the current manifest. See <a href="#">Manifest Imports</a> for details.
groups	Optional, a list of groups the project belongs to. See <a href="#">Project Groups and Active Projects</a> for details.
submodules	Optional. You can use this to make west update also update Git submodules defined by the project. See <a href="#">Git Submodules in Projects</a> for details.

**Defaults** The defaults subsection can provide default values for project attributes. In particular, the default remote name and revision can be specified here. Another way to write the same manifest we have been describing so far using defaults is:

```
manifest:
  defaults:
    remote: remotel
    revision: v1.3

  remotes:
    - name: remotel
      url-base: https://git.example.com/base1
    - name: remote2
      url-base: https://git.example.com/base2
```

(continues on next page)

(continued from previous page)

```

projects:
- name: proj1
  path: extra/project-1
  revision: master
- name: proj2
  repo-path: my-path
  remote: remote2
- name: proj3
  url: https://github.com/user/project-three
  revision: abcde413a111

```

The available defaults keys and their usage are in the following table.

Table 18: defaults keys

Key	Description
remote	Optional. This will be used for a project's remote if it does not have a url or remote key set.
revision	Optional. This will be used for a project's revision if it does not have one set. If not given, the default is master.

**Self** The `self` subsection can be used to control the manifest repository itself.

As an example, let's consider this snippet from the zephyr repository's `west.yml`:

```

manifest:
# ...
self:
  path: zephyr
  west-commands: scripts/west-commands.yml

```

This ensures that the zephyr repository is cloned into path `zephyr`, though as explained above that would have happened anyway if cloning from the default manifest URL, `https://github.com/zephyrproject-rtos/zephyr`. Since the zephyr repository does contain extension commands, its `self` entry declares the location of the corresponding `west-commands.yml` relative to the repository root.

The available `self` keys and their usage are in the following table.

Table 19: self keys

Key	Description
path	Optional. The path <code>west init</code> should clone the manifest repository into, relative to the west workspace topdir. If not given, the basename of the path component in the manifest repository URL will be used by default. For example, if the URL is <code>https://git.example.com/project-repo</code> , the manifest repository would be cloned to the directory <code>project-repo</code> .
west-commands	Optional. This is analogous to the same key in a project sequence element.
import	Optional. This is also analogous to the <code>projects</code> key, but allows importing projects from other files in the manifest repository. See <a href="#">Manifest Imports</a> .

**Version** The `version` subsection can be used to mark the lowest version of the manifest file schema that can parse this file's data:

```

manifest:
  version: "0.10"

```

(continues on next page)

(continued from previous page)

```
# marks that this file uses version 0.10 of the west manifest
# file format.
```

The pykwalify schema `manifest-schema.yml` in the west source code repository is used to validate the manifest section. The current manifest version is 0.10, which is supported by west version v0.10.x.

The version value may be "0.7", "0.8", "0.9", or "0.10". West v0.10.x can load manifests with any of these version values, while west v0.9.x can only load versions up to "0.9", and so on.

West halts with an error if you ask it to load a manifest file written in a version it cannot handle.

Quoting the version value as shown above forces the YAML parser to treat it as a string. Without quotes, 0.10 in YAML is just the floating point value 0.1. You can omit the quotes if the value is the same when cast to string, but it's best to include them. Always use quotes if you're not sure.

**Group-filter** See [Project Groups and Active Projects](#).

## Project Groups and Active Projects

You can use the `groups` and `group-filter` keys briefly described [above](#) to place projects into groups, and filter which groups are enabled. These keys appear in the manifest like this:

```
manifest:
  projects:
    - name: some-project
      groups: ...
  group-filter: ...
```

You can enable or disable project groups using `group-filter`. Projects whose groups are all disabled are *inactive*; west essentially ignores inactive projects unless explicitly requested not to.

The next section introduces project groups; the following sections describe [Enabled and Disabled Project Groups](#) and [Active and Inactive Projects](#). There are some basic examples in [Project Group Examples](#).

Finally, [Group Filters and Imports](#) provides a simplified overview of how `group-filter` interacts with the [Manifest Imports](#) feature.

**Project Groups** Inside `manifest: projects:`, you can add a project to one or more groups. The `groups` key is a list of group names. Group names are strings.

For example, in this manifest fragment:

```
manifest:
  projects:
    - name: project-1
      groups:
        - groupA
    - name: project-2
      groups:
        - groupB
        - groupC
    - name: project-3
```

The projects are in these groups:

- project-1: one group, named groupA
- project-2: two groups, named groupB and groupC

- `project-3`: no groups

Project group names must not contain commas (,), colons (:), or whitespace.

Group names must not begin with a dash (-) or the plus sign (+), but they may contain these characters elsewhere in their names. For example, `foo-bar` and `foo+bar` are valid groups, but `-foobar` and `+foobar` are not.

Group names are otherwise arbitrary strings. Group names are case sensitive.

As a restriction, no project may use both `import:` and `groups:`. (This avoids some edge cases whose semantics are difficult to specify.)

**Enabled and Disabled Project Groups** All project groups are enabled by default. You can enable or disable groups in both your manifest file and [Configuration](#).

Within a manifest file, `manifest: group-filter:` is a YAML list of groups to enable and disable.

To enable a group, prefix its name with a plus sign (+). For example, `groupA` is enabled in this manifest fragment:

```
manifest:
  group-filter: [+groupA]
```

Although this is redundant for groups that are already enabled by default, it can be used to override settings in an imported manifest file. See [Group Filters and Imports](#) for more information.

To disable a group, prefix its name with a dash (-). For example, `groupA` and `groupB` are disabled in this manifest fragment:

```
manifest:
  group-filter: [-groupA, -groupB]
```

---

**Note:** Since `group-filter` is a YAML list, you could have written this fragment as follows:

```
manifest:
  group-filter:
    - -groupA
    - -groupB
```

However, this syntax is harder to read and therefore discouraged.

---

In addition to the manifest file, you can control which groups are enabled and disabled using the `manifest.group-filter` configuration option. This option is a comma-separated list of groups to enable and/or disable.

To enable a group, add its name to the list prefixed with +. To disable a group, add its name prefixed with -. For example, setting `manifest.group-filter` to `+groupA, -groupB` enables `groupA`, and disables `groupB`.

The value of the configuration option overrides any data in the manifest file. You can think of this as if the `manifest.group-filter` configuration option is appended to the `manifest: group-filter:` list from YAML, with “last entry wins” semantics.

**Active and Inactive Projects** All projects are *active* by default. Projects with no groups are always active. A project is *inactive* if all of its groups are disabled. This is the only way to make a project inactive.

Most west commands that operate on projects will ignore inactive projects by default. For example, [west update](#) when run without arguments will not update inactive projects. As another example, running `west list` without arguments will not print information for inactive projects.

**Project Group Examples** This section contains example situations involving project groups and active projects. The examples use both `manifest: group-filter:` YAML lists and `manifest.group-filter` configuration lists, to show how they work together.

Note that the `defaults` and `remotes` data in the following manifests isn't relevant except to make the examples complete and self-contained.

**Example 1: no disabled groups** The entire manifest file is:

```
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB
    - name: baz

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is not set (you can ensure this by running `west config -D manifest.group-filter`).

No groups are disabled, because all groups are enabled by default. Therefore, all three projects (`foo`, `bar`, and `baz`) are active. Note that there is no way to make project `baz` inactive, since it has no groups.

**Example 2: Disabling one group via manifest** The entire manifest file is:

```
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB

  group-filter: [-groupA]

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is not set (you can ensure this by running `west config -D manifest.group-filter`).

Since `groupA` is disabled, project `foo` is inactive. Project `bar` is active, because `groupB` is enabled.

**Example 3: Disabling multiple groups via manifest** The entire manifest file is:

```
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB

  group-filter: [-groupA,-groupB]

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is not set (you can ensure this by running `west config -D manifest.group-filter`).

Both `foo` and `bar` are inactive, because all of their groups are disabled.

**Example 4: Disabling a group via configuration** The entire manifest file is:

```
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is set to `-groupA` (you can ensure this by running `west config manifest.group-filter -- -groupA`; the extra `--` is required so the argument parser does not treat `-groupA` as a command line option `-g` with value `roupA`).

Project `foo` is inactive because `groupA` has been disabled by the `manifest.group-filter` configuration option. Project `bar` is active because `groupB` is enabled.

**Example 5: Overriding a disabled group via configuration** The entire manifest file is:

```
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
    - name: baz
```

(continues on next page)

(continued from previous page)

```
groups:
  - groupA
  - groupB

group-filter: [-groupA]

defaults:
  remote: example-remote
remotes:
  - name: example-remote
    url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is set to `+groupA` (you can ensure this by running `west config manifest.group-filter +groupA`).

In this case, `groupA` is enabled: the `manifest.group-filter` configuration option has higher precedence than the `manifest: group-filter: [-groupA]` content in the manifest file.

Therefore, projects `foo` and `bar` are both active.

**Example 6: Overriding multiple disabled groups via configuration** The entire manifest file is:

```
manifest:
  projects:
    - name: foo
    - name: bar
    groups:
      - groupA
    - name: baz
    groups:
      - groupA
      - groupB

  group-filter: [-groupA,-groupB]

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is set to `+groupA,+groupB` (you can ensure this by running `west config manifest.group-filter "+groupA,+groupB"`).

In this case, both `groupA` and `groupB` are enabled, because the configuration value overrides the manifest file for both groups.

Therefore, projects `foo` and `bar` are both active.

**Example 7: Disabling multiple groups via configuration** The entire manifest file is:

```
manifest:
  projects:
    - name: foo
    - name: bar
    groups:
      - groupA
```

(continues on next page)

(continued from previous page)

```

- name: baz
  groups:
    - groupA
    - groupB

defaults:
  remote: example-remote
remotes:
- name: example-remote
  url-base: https://git.example.com

```

The `manifest.group-filter` configuration option is set to `-groupA,-groupB` (you can ensure this by running `west config manifest.group-filter -- "-groupA,-groupB"`).

In this case, both `groupA` and `groupB` are disabled.

Therefore, projects `foo` and `bar` are both inactive.

**Group Filters and Imports** This section provides a simplified description of how the `manifest:group-filter:` value behaves when combined with [Manifest Imports](#). For complete details, see [Manifest Import Details](#).

**Warning:** The below semantics apply to west v0.10.0 and later. West v0.9.x semantics are different, and combining `group-filter` with `import` in west v0.9.x is discouraged.

In short:

- if you only import one manifest, any groups it disables in its `group-filter` are also disabled in your manifest
- you can override this in your manifest file's `manifest:group-filter:` value, your workspace's `manifest.group-filter` configuration option, or both

Here are some examples.

**Example 1: no overrides** You are using this parent/`west.yml` manifest:

```

# parent/west.yml:
manifest:
  projects:
    - name: child
      url: https://git.example.com/child
      import: true
    - name: project-1
      url: https://git.example.com/project-1
      groups:
        - unstable

```

And `child/west.yml` contains:

```

# child/west.yml:
manifest:
  group-filter: [-unstable]
  projects:
    - name: project-2
      url: https://git.example.com/project-2

```

(continues on next page)

(continued from previous page)

```
- name: project-3
  url: https://git.example.com/project-3
  groups:
    - unstable
```

Only child and project-2 are active in the resolved manifest.

The unstable group is disabled in child/west.yml, and that is not overridden in parent/west.yml. Therefore, the final group-filter for the resolved manifest is [-unstable].

Since project-1 and project-3 are in the unstable group and are not in any other group, they are inactive.

**Example 2: overriding an imported group-filter via manifest** You are using this parent/west.yml manifest:

```
# parent/west.yml:
manifest:
  group-filter: [+unstable,-optional]
  projects:
    - name: child
      url: https://git.example.com/child
      import: true
    - name: project-1
      url: https://git.example.com/project-1
      groups:
        - unstable
```

And child/west.yml contains:

```
# child/west.yml:
manifest:
  group-filter: [-unstable]
  projects:
    - name: project-2
      url: https://git.example.com/project-2
      groups:
        - optional
    - name: project-3
      url: https://git.example.com/project-3
      groups:
        - unstable
```

Only the child, project-1, and project-3 projects are active.

The [-unstable] group filter in child/west.yml is overridden in parent/west.yml, so the unstable group is enabled. Since project-1 and project-3 are in the unstable group, they are active.

The same parent/west.yml file disables the optional group, so project-2 is inactive.

The final group filter specified by parent/west.yml is [+unstable,-optional].

**Example 3: overriding an imported group-filter via configuration** You are using this parent/west.yml manifest:

```
# parent/west.yml:
manifest:
  projects:
```

(continues on next page)

(continued from previous page)

```
- name: child
  url: https://git.example.com/child
  import: true
- name: project-1
  url: https://git.example.com/project-1
  groups:
    - unstable
```

And child/west.yml contains:

```
# child/west.yml:
manifest:
  group-filter: [-unstable]
  projects:
    - name: project-2
      url: https://git.example.com/project-2
      groups:
        - optional
    - name: project-3
      url: https://git.example.com/project-3
      groups:
        - unstable
```

If you run:

```
west config manifest.group-filter +unstable,-optional
```

Then only the child, project-1, and project-3 projects are active.

The -unstable group filter in child/west.yml is overridden in the manifest.group-filter configuration option, so the unstable group is enabled. Since project-1 and project-3 are in the unstable group, they are active.

The same configuration option disables the optional group, so project-2 is inactive.

The final group filter specified by parent/west.yml and the manifest.group-filter configuration option is [+unstable,-optional].

## Git Submodules in Projects

You can use the submodules keys briefly described [above](#) to force west update to also handle any [Git submodules](#) configured in project's git repository. The submodules key can appear inside projects, like this:

```
manifest:
  projects:
    - name: some-project
      submodules: ...
```

The submodules key can be a boolean or a list of mappings. We'll describe these in order.

**Option 1: Boolean** This is the easiest way to use submodules.

If submodules is true as a projects attribute, west update will recursively update the project's Git submodules whenever it updates the project itself. If it's false or missing, it has no effect.

For example, let's say you have a source code repository foo, which has some submodules, and you want west update to keep all of them in sync, along with another project named bar in the same workspace.

You can do that with this manifest file:

```
manifest:
  projects:
    - name: foo
      submodules: true
    - name: bar
```

Here, `west update` will initialize and update all submodules in `foo`. If `bar` has any submodules, they are ignored, because `bar` does not have a `submodules` value.

**Option 2: List of mappings** The `submodules` key may be a list of mappings, one list element for each desired submodule. Each submodule listed is updated recursively. You can still track and update unlisted submodules with `git` commands manually; present or not they will be completely ignored by `west`.

The `path` key must match exactly the path of one submodule relative to its parent `west` project, as shown in the output of `git submodule status`. The `name` key is optional and not used by `west` for now; it's not passed to `git submodule` commands either. The `name` key was briefly mandatory in `west` version 0.9.0, but was made optional in 0.9.1.

For example, let's say you have a source code repository `foo`, which has many submodules, and you want `west update` to keep some but not all of them in sync, along with another project named `bar` in the same workspace.

You can do that with this manifest file:

```
manifest:
  projects:
    - name: foo
      submodules:
        - path: path/to/foo-first-sub
        - name: foo-second-sub
          path: path/to/foo-second-sub
    - name: bar
```

Here, `west update` will recursively initialize and update just the submodules in `foo` with paths `path/to/foo-first-sub` and `path/to/foo-second-sub`. Any submodules in `bar` are still ignored.

## Manifest Imports

You can use the `import` key briefly described above to include projects from other manifest files in your `west.yml`. This key can be either a `project` or `self` section attribute:

```
manifest:
  projects:
    - name: some-project
      import: ...
  self:
    import: ...
```

You can use a “`self: import:`” to load additional files from the repository containing your `west.yml`. You can use a “`project: ... import:`” to load additional files defined in that project's Git history.

West resolves the final manifest from individual manifest files in this order:

1. imported files in `self`
2. your `west.yml` file
3. imported files in `projects`

During resolution, west ignores projects which have already been defined in other files. For example, a project named `foo` in your `west.yml` makes west ignore other projects named `foo` imported from your projects list.

The `import` key can be a boolean, path, mapping, or sequence. We'll describe these in order, using examples:

- **Boolean**
  - *Example 1.1: Downstream of a Zephyr release*
  - *Example 1.2: “Rolling release” Zephyr downstream*
  - *Example 1.3: Downstream of a Zephyr release, with module fork*
- **Relative path**
  - *Example 2.1: Downstream of a Zephyr release with explicit path*
  - *Example 2.2: Downstream with directory of manifest files*
  - *Example 2.3: Continuous Integration overrides*
- **Mapping with additional configuration**
  - *Example 3.1: Downstream with name allowlist*
  - *Example 3.2: Downstream with path allowlist*
  - *Example 3.3: Downstream with path blocklist*
  - *Example 3.4: Import into a subdirectory*
- **Sequence of paths and mappings**
  - *Example 4.1: Downstream with sequence of manifest files*
  - *Example 4.2: Import order illustration*

A more [formal description](#) of how this works is last, after the examples.

**Troubleshooting Note** If you're using this feature and find west's behavior confusing, try [resolving your manifest](#) to see the final results after imports are done.

**Option 1: Boolean** This is the easiest way to use `import`.

If `import` is `true` as a projects attribute, west imports projects from the `west.yml` file in that project's root directory. If it's `false` or missing, it has no effect. For example, this manifest would import `west.yml` from the `p1` git repository at revision `v1.0`:

```
manifest:
# ...
projects:
- name: p1
  revision: v1.0
  import: true      # Import west.yml from p1's v1.0 git tag
- name: p2
  import: false     # Nothing is imported from p2.
- name: p3
  # Nothing is imported from p3 either.
```

It's an error to set `import` to either `true` or `false` inside `self`, like this:

```
manifest:
# ...
self:
  import: true      # Error
```

**Example 1.1: Downstream of a Zephyr release** You have a source code repository you want to use with Zephyr v1.14.1 LTS. You want to maintain the whole thing using west. You don't want to modify any of the mainline repositories.

In other words, the west workspace you want looks like this:

```
my-downstream/
├── .west/                # west directory
├── zephyr/               # mainline zephyr repository
│   └── west.yml          # the v1.14.1 version of this file is imported
├── modules/             # modules from mainline zephyr
│   ├── hal/
│   └── [...other directories...]
├── [ ... other projects ...] # other mainline repositories
├── my-repo/             # your downstream repository
│   ├── west.yml          # main manifest importing zephyr/west.yml v1.14.1
│   └── [...other files...]
```

You can do this with the following my-repo/west.yml:

```
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v1.14.1
      import: true
```

You can then create the workspace on your computer like this, assuming my-repo is hosted at `https://git.example.com/my-repo`:

```
west init -m https://git.example.com/my-repo my-downstream
cd my-downstream
west update
```

After `west init`, my-downstream/my-repo will be cloned.

After `west update`, all of the projects defined in the zephyr repository's `west.yml` at revision `v1.14.1` will be cloned into my-downstream as well.

You can add and commit any code to my-repo you please at this point, including your own Zephyr applications, drivers, etc. See [Application Development](#).

**Example 1.2: “Rolling release” Zephyr downstream** This is similar to [Example 1.1: Downstream of a Zephyr release](#), except we'll use revision: `main` for the zephyr repository:

```
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: main
      import: true
```

You can create the workspace in the same way:

```
west init -m https://git.example.com/my-repo my-downstream
cd my-downstream
west update
```

This time, whenever you run `west update`, the special [manifest-rev](#) branch in the zephyr repository will be updated to point at a newly fetched main branch tip from the URL <https://github.com/zephyrproject-rtos/zephyr>.

The contents of `zephyr/west.yml` at the new `manifest-rev` will then be used to import projects from Zephyr. This lets you stay up to date with the latest changes in the Zephyr project. The cost is that running `west update` will not produce reproducible results, since the remote main branch can change every time you run it.

It's also important to understand that `west` **ignores your working tree's** `zephyr/west.yml` entirely when resolving imports. `West` always uses the contents of imported manifests as they were committed to the latest `manifest-rev` when importing from a project.

You can only import manifest from the file system if they are in your manifest repository's working tree. See [Example 2.2: Downstream with directory of manifest files](#) for an example.

**Example 1.3: Downstream of a Zephyr release, with module fork** This manifest is similar to the one in [Example 1.1: Downstream of a Zephyr release](#), except it:

- is a downstream of Zephyr 2.0
- includes a downstream fork of the `modules/hal/nordic` [module](#) which was included in that release

```
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
    - name: my-remote
      url-base: https://git.example.com
  projects:
    - name: hal_nordic          # higher precedence
      remote: my-remote
      revision: my-sha
      path: modules/hal/nordic
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v2.0.0
      import: true              # imported projects have lower precedence

# subset of zephyr/west.yml contents at v2.0.0:
manifest:
  defaults:
    remote: zephyrproject-rtos
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    # ...
    - name: hal_nordic          # lower precedence, values ignored
      path: modules/hal/nordic
      revision: another-sha
```

With this manifest file, the project named `hal_nordic`:

- is cloned from `https://git.example.com/hal_nordic` instead of `https://github.com/zephyrproject-rtos/hal_nordic`.
- is updated to commit `my-sha` by `west update`, instead of the mainline commit `another-sha`

In other words, when your top-level manifest defines a project, like `hal_nordic`, `west` will ignore any other definition it finds later on while resolving imports.

This does mean you have to copy the path: `modules/hal/nordic` value into `my-repo/west.yml` when defining `hal_nordic` there. The value from `zephyr/west.yml` is ignored entirely. See [Resolving Manifests](#) for troubleshooting advice if this gets confusing in practice.

When you run `west update`, `west` will:

- update `zephyr's` `manifest-rev` to point at the `v2.0.0` tag
- import `zephyr/west.yml` at that `manifest-rev`
- locally check out the `v2.0.0` revisions for all `zephyr` projects except `hal_nordic`
- update `hal_nordic` to `my-sha` instead of `another-sha`

**Option 2: Relative path** The `import` value can also be a relative path to a manifest file or a directory containing manifest files. The path is relative to the root directory of the projects or `self` repository the `import` key appears in.

Here is an example:

```
manifest:
  projects:
    - name: project-1
      revision: v1.0
      import: west.yml
    - name: project-2
      revision: main
      import: p2-manifests
  self:
    import: submanifests
```

This will import the following:

- the contents of `project-1/west.yml` at `manifest-rev`, which points at tag `v1.0` after running `west update`
- any YAML files in the directory tree `project-2/p2-manifests` at the latest commit in the main branch, as fetched by `west update`, sorted by file name
- YAML files in `submanifests` in your manifest repository, as they appear on your file system, sorted by file name

Notice how `projects` imports get data from Git using `manifest-rev`, while `self` imports get data from your file system. This is because as usual, `west` leaves version control for your manifest repository up to you.

**Example 2.1: Downstream of a Zephyr release with explicit path** This is an explicit way to write an equivalent manifest to the one in [Example 1.1: Downstream of a Zephyr release](#).

```
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
```

(continues on next page)

(continued from previous page)

```
remote: zephyrproject-rtos
revision: v1.14.1
import: west.yml
```

The setting `import: west.yml` means to use the file `west.yml` inside the zephyr project. This example is contrived, but shows the idea.

This can be useful in practice when the name of the manifest file you want to import is not `west.yml`.

**Example 2.2: Downstream with directory of manifest files** Your Zephyr downstream has a lot of additional repositories. So many, in fact, that you want to split them up into multiple manifest files, but keep track of them all in a single manifest repository, like this:

```
my-repo/
├── submanifests
│   ├── 01-libraries.yml
│   ├── 02-vendor-hals.yml
│   └── 03-applications.yml
└── west.yml
```

You want to add all the files in `my-repo/submanifests` to the main manifest file, `my-repo/west.yml`, in addition to projects in `zephyr/west.yml`. You want to track the latest development code in the Zephyr repository's main branch instead of using a fixed revision.

Here's how:

```
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: main
      import: true
  self:
    import: submanifests
```

Manifest files are imported in this order during resolution:

1. `my-repo/submanifests/01-libraries.yml`
2. `my-repo/submanifests/02-vendor-hals.yml`
3. `my-repo/submanifests/03-applications.yml`
4. `my-repo/west.yml`
5. `zephyr/west.yml`

**Note:** The `.yml` file names are prefixed with numbers in this example to make sure they are imported in the specified order.

You can pick arbitrary names. West sorts files in a directory by name before importing.

Notice how the manifests in `submanifests` are imported *before* `my-repo/west.yml` and `zephyr/west.yml`. In general, an `import` in the `self` section is processed before the manifest files in `projects` and the main manifest file.

This means projects defined in `my-repo/submanifests` take highest precedence. For example, if `01-libraries.yml` defines `hal_nordic`, the project by the same name in `zephyr/west.yml` is simply ignored. As usual, see [Resolving Manifests](#) for troubleshooting advice.

This may seem strange, but it allows you to redefine projects “after the fact”, as we’ll see in the next example.

**Example 2.3: Continuous Integration overrides** Your continuous integration system needs to fetch and test multiple repositories in your west workspace from a developer’s forks instead of your mainline development trees, to see if the changes all work well together.

Starting with [Example 2.2: Downstream with directory of manifest files](#), the CI scripts add a file `00-ci.yml` in `my-repo/submanifests`, with these contents:

```
# my-repo/submanifests/00-ci.yml:
manifest:
  projects:
    - name: a-vendor-hal
      url: https://github.com/a-developer/hal
      revision: a-pull-request-branch
    - name: an-application
      url: https://github.com/a-developer/application
      revision: another-pull-request-branch
```

The CI scripts run `west update` after generating this file in `my-repo/submanifests`. The projects defined in `00-ci.yml` have higher precedence than other definitions in `my-repo/submanifests`, because the name `00-ci.yml` comes before the other file names.

Thus, `west update` always checks out the developer’s branches in the projects named `a-vendor-hal` and `an-application`, even if those same projects are also defined elsewhere.

**Option 3: Mapping** The `import` key can also contain a mapping with the following keys:

- `file`: Optional. The name of the manifest file or directory to import. This defaults to `west.yml` if not present.
- `name-allowlist`: Optional. If present, a name or sequence of project names to include.
- `path-allowlist`: Optional. If present, a path or sequence of project paths to match against. This is a shell-style globbing pattern, currently implemented with [pathlib](#). Note that this means case sensitivity is platform specific.
- `name-blocklist`: Optional. Like `name-allowlist`, but contains project names to exclude rather than include.
- `path-blocklist`: Optional. Like `path-allowlist`, but contains project paths to exclude rather than include.
- `path-prefix`: Optional (new in v0.8.0). If given, this will be prepended to the project’s path in the workspace, as well as the paths of any imported projects. This can be used to place these projects in a subdirectory of the workspace.

Allowlists override blocklists if both are given. For example, if a project is blocked by path, then allowed by name, it will still be imported.

**Example 3.1: Downstream with name allowlist** Here is a pair of manifest files, representing a mainline and a downstream. The downstream doesn’t want to use all the mainline projects, however. We’ll assume the mainline `west.yml` is hosted at `https://git.example.com/mainline/manifest`.

```
# mainline west.yml:
manifest:
  projects:
    - name: mainline-app          # included
      path: examples/app
      url: https://git.example.com/mainline/app
    - name: lib
      path: libraries/lib
      url: https://git.example.com/mainline/lib
    - name: lib2                  # included
      path: libraries/lib2
      url: https://git.example.com/mainline/lib2

# downstream west.yml:
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
    import:
      name-allowlist:
        - mainline-app
        - lib2
    - name: downstream-app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
```

An equivalent manifest in a single file would be:

```
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
    - name: downstream-app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
    - name: mainline-app          # imported
      path: examples/app
      url: https://git.example.com/mainline/app
    - name: lib2                  # imported
      path: libraries/lib2
      url: https://git.example.com/mainline/lib2
```

If an allowlist had not been used, the `lib` project from the mainline manifest would have been imported.

**Example 3.2: Downstream with path allowlist** Here is an example showing how to allowlist mainline’s libraries only, using `path-allowlist`.

```
# mainline west.yml:
manifest:
  projects:
    - name: app
      path: examples/app
      url: https://git.example.com/mainline/app
```

(continues on next page)

(continued from previous page)

```
- name: lib
  path: libraries/lib          # included
  url: https://git.example.com/mainline/lib
- name: lib2
  path: libraries/lib2        # included
  url: https://git.example.com/mainline/lib2

# downstream west.yml:
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
      import:
        path-allowlist: libraries/*
    - name: app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
```

An equivalent manifest in a single file would be:

```
manifest:
  projects:
    - name: lib          # imported
      path: libraries/lib
      url: https://git.example.com/mainline/lib
    - name: lib2        # imported
      path: libraries/lib2
      url: https://git.example.com/mainline/lib2
    - name: mainline
      url: https://git.example.com/mainline/manifest
    - name: app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
```

**Example 3.3: Downstream with path blocklist** Here’s an example showing how to block all vendor HALs from mainline by common path prefix in the workspace, add your own version for the chip you’re targeting, and keep everything else.

```
# mainline west.yml:
manifest:
  defaults:
    remote: mainline
  remotes:
    - name: mainline
      url-base: https://git.example.com/mainline
  projects:
    - name: app
    - name: lib
      path: libraries/lib
    - name: lib2
      path: libraries/lib2
```

(continues on next page)

(continued from previous page)

```

- name: hal_foo
  path: modules/hals/foo      # excluded
- name: hal_bar
  path: modules/hals/bar      # excluded
- name: hal_baz
  path: modules/hals/baz      # excluded

# downstream west.yml:
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
      import:
        path-blocklist: modules/hals/*
    - name: hal_foo
      path: modules/hals/foo
      url: https://git.example.com/downstream/hal_foo

```

An equivalent manifest in a single file would be:

```

manifest:
  defaults:
    remote: mainline
  remotes:
    - name: mainline
      url-base: https://git.example.com/mainline
  projects:
    - name: app                # imported
    - name: lib                # imported
      path: libraries/lib
    - name: lib2               # imported
      path: libraries/lib2
    - name: mainline
      repo-path: https://git.example.com/mainline/manifest
    - name: hal_foo
      path: modules/hals/foo
      url: https://git.example.com/downstream/hal_foo

```

**Example 3.4: Import into a subdirectory** You want to import a manifest and its projects, placing everything into a subdirectory of your west workspace.

For example, suppose you want to import this manifest from project foo, adding this project and its projects bar and baz to your workspace:

```

# foo/west.yml:
manifest:
  defaults:
    remote: example
  remotes:
    - name: example
      url-base: https://git.example.com
  projects:
    - name: bar
    - name: baz

```

Instead of importing these into the top level workspace, you want to place all three project repositories in an external-code subdirectory, like this:

```
workspace/
├─ external-code/
│   ├── foo/
│   ├── bar/
│   └─ baz/
```

You can do this using this manifest:

```
manifest:
  projects:
    - name: foo
      url: https://git.example.com/foo
      import:
        path-prefix: external-code
```

An equivalent manifest in a single file would be:

```
# foo/west.yml:
manifest:
  defaults:
    remote: example
  remotes:
    - name: example
      url-base: https://git.example.com
  projects:
    - name: foo
      path: external-code/foo
    - name: bar
      path: external-code/bar
    - name: baz
      path: external-code/baz
```

**Option 4: Sequence** The `import` key can also contain a sequence of files, directories, and mappings.

**Example 4.1: Downstream with sequence of manifest files** This example manifest is equivalent to the manifest in [Example 2.2: Downstream with directory of manifest files](#), with a sequence of explicitly named files.

```
# my-repo/west.yml:
manifest:
  projects:
    - name: zephyr
      url: https://github.com/zephyrproject-rtos/zephyr
      import: west.yml
  self:
    import:
      - submanifests/01-libraries.yml
      - submanifests/02-vendor-hals.yml
      - submanifests/03-applications.yml
```

**Example 4.2: Import order illustration** This more complicated example shows the order that west imports manifest files:

```
# my-repo/west.yml
manifest:
  # ...
  projects:
    - name: my-library
    - name: my-app
    - name: zephyr
      import: true
    - name: another-manifest-repo
      import: submanifests
  self:
    import:
      - submanifests/libraries.yml
      - submanifests/vendor-hals.yml
      - submanifests/applications.yml
  defaults:
    remote: my-remote
```

For this example, west resolves imports in this order:

1. the listed files in `my-repo/submanifests` are first, in the order they occur (e.g. `libraries.yml` comes before `applications.yml`, since this is a sequence of files), since the `self: import:` is always imported first
2. `my-repo/west.yml` is next (with projects `my-library` etc. as long as they weren't already defined somewhere in submanifests)
3. `zephyr/west.yml` is after that, since that's the first `import` key in the projects list in `my-repo/west.yml`
4. files in `another-manifest-repo/submanifests` are last (sorted by file name), since that's the final project import

**Manifest Import Details** This section describes how west resolves a manifest file that uses `import` a bit more formally.

**Overview** The `import` key can appear in a west manifest's `projects` and `self` sections. The general case looks like this:

```
# Top-level manifest file.
manifest:
  projects:
    - name: foo
      import: import-1
    - name: bar
      import: import-2
    # ...
    - name: baz
      import: import-N
  self:
    import: self-import
```

Import keys are optional. If any of `import-1`, ..., `import-N` are missing, west will not import additional manifest data from that project. If `self-import` is missing, no additional files in the manifest repository (beyond the top-level file) are imported.

The ultimate outcomes of resolving manifest imports are:

- a `projects` list, which is produced by combining the projects defined in the top-level file with those defined in imported files
- a set of extension commands, which are drawn from the `west-commands` keys in the top-level file and any imported files
- a `group-filter` list, which is produced by combining the top-level and any imported filters

Importing is done in this order:

1. Manifests from `self-import` are imported first.
2. The top-level manifest file's definitions are handled next.
3. Manifests from `import-1`, ..., `import-N`, are imported in that order.

When an individual `import` key refers to multiple manifest files, they are processed in this order:

- If the value is a relative path naming a directory (or a map whose `file` is a directory), the manifest files it contains are processed in lexicographic order – i.e., sorted by file name.
- If the value is a sequence, its elements are recursively imported in the order they appear.

This process recurses if necessary. E.g., if `import-1` produces a manifest file that contains an `import` key, it is resolved recursively using the same rules before its contents are processed further.

**Projects** This section describes how the final `projects` list is created.

Projects are identified by name. If the same name occurs in multiple manifests, the first definition is used, and subsequent definitions are ignored. For example, if `import-1` contains a project named `bar`, that is ignored, because the top-level `west.yml` has already defined a project by that name.

The contents of files named by `import-1` through `import-N` are imported from Git at the latest `manifest-rev` revisions in their projects. These revisions can be updated to the values `rev-1` through `rev-N` by running `west update`. If any `manifest-rev` reference is missing or out of date, `west update` also fetches project data from the remote fetch URL and updates the reference.

Also note that all imported manifests, from the root manifest to the repository which defines a project `P`, must be up to date in order for `west` to update `P` itself. For example, this means `west update P` would update `manifest-rev` in the `baz` project if `baz/west.yml` defines `P`, as well as updating the `manifest-rev` branch in the local git clone of `P`. Confusingly, updating `baz` may result in the removal of `P` from `baz/west.yml`, which “should” cause `west update P` to fail with an unrecognized project!

For this reason, it's not possible to run `west update P` if `P` is defined in an imported manifest; you must update this project along with all the others with a plain `west update`.

By default, `west` won't fetch any project data over the network if a project's revision is a SHA or tag which is already available locally, so updating the extra projects shouldn't take too much time unless it's really needed. See the documentation for the [update.fetch](#) configuration option for more information.

**Extensions** All extension commands defined using `west-commands` keys discovered while handling imports are available in the resolved manifest.

If an imported manifest file has a `west-commands:` definition in its `self:` section, the extension commands defined there are added to the set of available extensions at the time the manifest is imported. They will thus take precedence over any extension commands with the same names added later on.

**Group filters** The resolved manifest has a `group-filter` value which is the result of concatenating the `group-filter` values in the top-level manifest and any imported manifests.

Manifest files which appear earlier in the import order have higher precedence and are therefore concatenated later into the final `group-filter`.

In other words, let:

- the submanifest resolved from `self-import` have group filter `self-filter`
- the top-level manifest file have group filter `top-filter`
- the submanifests resolved from `import-1` through `import-N` have group filters `filter-1` through `filter-N` respectively

The final resolved `group-filter` value is then `filter1 + filter-2 + ... + filter-N + top-filter + self-filter`, where `+` here refers to list concatenation.

---

**Important:** The order that filters appear in the above list matters.

The last filter element in the final concatenated list “wins” and determines if the group is enabled or disabled.

---

For example, in `[-foo] + [+foo]`, group `foo` is *enabled*. However, in `[+foo] + [-foo]`, group `foo` is *disabled*.

For simplicity, west and this documentation may elide concatenated group filter elements which are redundant using these rules. For example, `[+foo] + [-foo]` could be written more simply as `[-foo]`, for the reasons given above. As another example, `[-foo] + [+foo]` could be written as the empty list `[]`, since all groups are enabled by default.

## Manifest Command

The `west manifest` command can be used to manipulate manifest files. It takes an action, and action-specific arguments.

The following sections describe each action and provides a basic signature for simple uses. Run `west manifest --help` for full details on all options.

**Resolving Manifests** The `--resolve` action outputs a single manifest file equivalent to your current manifest and all its *imported manifests*:

```
west manifest --resolve [-o outfile]
```

The main use for this action is to see the “final” manifest contents after performing any imports.

To print detailed information about each imported manifest file and how projects are handled during manifest resolution, set the maximum verbosity level using `-v`:

```
west -v manifest --resolve
```

**Freezing Manifests** The `--freeze` action outputs a frozen manifest:

```
west manifest --freeze [-o outfile]
```

A “frozen” manifest is a manifest file where every project’s revision is a SHA. You can use `--freeze` to produce a frozen manifest that’s equivalent to your current manifest file. The `-o` option specifies an output file; if not given, standard output is used.

**Validating Manifests** The `--validate` action either succeeds if the current manifest file is valid, or fails with an error:

```
west manifest --validate
```

The error message can help diagnose errors.

**Get the manifest path** The `--path` action prints the path to the top level manifest file:

```
west manifest --path
```

The output is something like `/path/to/workspace/west.yml`. The path format depends on your operating system.

## 8.20.8 Configuration

This page documents west's configuration file system, the `west config` command, and configuration options used by built-in commands. For API documentation on the `west.configuration` module, see [west-apis-configuration](#).

### West Configuration Files

West's configuration file syntax is INI-like; here is an example file:

```
[manifest]
path = zephyr

[zephyr]
base = zephyr
```

Above, the `manifest` section has option `path` set to `zephyr`. Another way to say the same thing is that `manifest.path` is `zephyr` in this file.

There are three types of configuration file:

1. **System:** Settings in this file affect west's behavior for every user logged in to the computer. Its location depends on the platform:
  - Linux: `/etc/westconfig`
  - macOS: `/usr/local/etc/westconfig`
  - Windows: `%PROGRAMDATA%\west\config`
2. **Global** (per user): Settings in this file affect how west behaves when run by a particular user on the computer.
  - All platforms: the default is `.westconfig` in the user's home directory.
  - Linux note: if the environment variable `XDG_CONFIG_HOME` is set, then `$XDG_CONFIG_HOME/west/config` is used.
  - Windows note: the following environment variables are tested to find the home directory: `%HOME%`, then `%USERPROFILE%`, then a combination of `%HOMEDRIVE%` and `%HOMEPATH%`.
3. **Local:** Settings in this file affect west's behavior for the current west workspace. The file is `.west/config`, relative to the workspace's root directory.

A setting in a file which appears lower down on this list overrides an earlier setting. For example, if `color.ui` is `true` in the system's configuration file, but `false` in the workspace's, then the final value is `false`. Similarly, settings in the user configuration file override system settings, and so on.

### west config

The built-in `config` command can be used to get and set configuration values. You can pass `west config` the options `--system`, `--global`, or `--local` to specify which configuration file to use. Only one of these can be used at a time. If none is given, then writes default to `--local`, and reads show the final value after applying overrides.

Some examples for common uses follow; run `west config -h` for detailed help, and see [Built-in Configuration Options](#) for more details on built-in options.

To set `manifest.path` to `some-other-manifest`:

```
west config manifest.path some-other-manifest
```

Doing the above means that commands like `west update` will look for the west manifest inside the `some-other-manifest` directory (relative to the workspace root directory) instead of the directory given to `west init`, so be careful!

To read `zephyr.base`, the value which will be used as `ZEPHYR_BASE` if it is unset in the calling environment (also relative to the workspace root):

```
west config zephyr.base
```

You can switch to another zephyr repository without changing `manifest.path` – and thus the behavior of commands like `west update` – using:

```
west config zephyr.base some-other-zephyr
```

This can be useful if you use commands like `git worktree` to create your own zephyr directories, and want commands like `west build` to use them instead of the zephyr repository specified in the manifest. (You can go back to using the directory in the upstream manifest by running `west config zephyr.base zephyr.`)

To set `color.ui` to `false` in the global (user-wide) configuration file, so that west will no longer print colored output for that user when run in any workspace:

```
west config --global color.ui false
```

To undo the above change:

```
west config --global color.ui true
```

## Built-in Configuration Options

The following table documents configuration options supported by west's built-in commands. Configuration options supported by Zephyr's extension commands are documented in the pages for those commands.

Option	Description
<code>color.ui</code>	Boolean. If true (the default), then west output is colorized when stdout is a terminal.
<code>commands.allow_extensions</code>	Boolean, default true, disables <a href="#">Extensions</a> if false
<code>manifest.file</code>	String, default <code>west.yml</code> . Relative path from the manifest repository root directory to the manifest file used by <code>west init</code> and other commands which parse the manifest.
<code>manifest.group-filter</code>	String, default empty. A comma-separated list of project groups to enable and disable within the workspace. Prefix enabled groups with + and disabled groups with -. For example, the value <code>"+foo,-bar"</code> enables group <code>foo</code> and disables <code>bar</code> . See <a href="#">Project Groups and Active Projects</a> .
<code>manifest.path</code>	String, relative path from the west workspace root directory to the manifest repository used by <code>west update</code> and other commands which parse the manifest. Set locally by <code>west init</code> .
<code>update.fetch</code>	String, one of "smart" (the default behavior starting in v0.6.1) or "always" (the previous behavior). If set to "smart", the <a href="#">west update</a> command will skip fetching from project remotes when those projects' revisions in the manifest file are SHAs or tags which are already available locally. The "always" behavior is to unconditionally fetch from the remote.
<code>update.name-cache</code>	String. If non-empty, west update will use its value as the <code>--name-cache</code> option's value if not given on the command line.
<code>update.narrow</code>	Boolean. If true, west update behaves as if <code>--narrow</code> was given on the command line. The default is false.
<code>update.path-cache</code>	String. If non-empty, west update will use its value as the <code>--path-cache</code> option's value if not given on the command line.
<code>update.sync-submodules</code>	Boolean. If true (the default), <a href="#">west update</a> will synchronize Git submodules before updating them.
<code>zephyr.base</code>	String, default value to set for the <code>ZEPHYR_BASE</code> environment variable while the west command is running. By default, this is set to the path to the manifest project with path <code>zephyr</code> (if there is one) during <code>west init</code> . If the variable is already set, then this setting is ignored unless <code>zephyr.base-prefer</code> is "configfile".
<code>zephyr.base-prefer</code>	String, one the values "env" and "configfile". If set to "env" (the default), setting <code>ZEPHYR_BASE</code> in the calling environment overrides the value of the <code>zephyr.base</code> configuration option. If set to "configfile", the configuration option wins instead.

### 8.20.9 Extensions

West is “pluggable”: you can add your own commands to west without editing its source code. These are called **west extension commands**, or just “extensions” for short. Extensions show up in the `west --help` output in a special section for the project which defines them. This page provides general information on west extension commands, and has a tutorial for writing your own.

Some commands you can run when using west with Zephyr, like the ones used to [build, flash, and debug](#) and the [ones described here](#), are extensions. That's why help for them shows up like this in `west --help`:

```
commands from project at "zephyr":
  completion:    display shell completion scripts
  boards:        display information about supported boards
  build:         compile a Zephyr application
  sign:          sign a Zephyr binary for bootloader chain-loading
  flash:         flash and run a binary on a board
  debug:         flash and interactively debug a Zephyr application
```

(continues on next page)

(continued from previous page)

```
debugserver:      connect to board and launch a debug server
attach:           interactively debug a board
```

See `zephyr/scripts/west-commands.yml` and the `zephyr/scripts/west_commands` directory for the implementation details.

### Disabling Extension Commands

To disable support for extension commands, set the `commands.allow_extensions` [configuration](#) option to `false`. To set this globally for whenever you run `west`, use:

```
west config --global commands.allow_extensions false
```

If you want to, you can then re-enable them in a particular `west` workspace with:

```
west config --local commands.allow_extensions true
```

Note that the files containing extension commands are not imported by `west` unless the commands are explicitly run. See below for details.

### Adding a West Extension

There are three steps to adding your own extension:

1. Write the code implementing the command.
2. Add information about it to a `west-commands.yml` file.
3. Make sure the `west-commands.yml` file is referenced in the west manifest.

Note that `west` ignores extension commands whose names are the same as a built-in command.

**Step 1: Implement Your Command** Create a Python file to contain your command implementation (see the “Meta > Requires” information on the [west PyPI page](#) for details on the currently supported versions of Python). You can put it in anywhere in any project tracked by your west manifest, or the manifest repository itself. This file must contain a subclass of the `west.commands.WestCommand` class; this class will be instantiated and used when your extension is run.

Here is a basic skeleton you can use to get started. It contains a subclass of `WestCommand`, with implementations for all the abstract methods. For more details on the `west` APIs you can use, see `west-apis`.

```
'''my_west_extension.py

Basic example of a west extension.'''

from textwrap import dedent          # just for nicer code indentation

from west.commands import WestCommand # your extension must subclass this
from west import log                 # use this for user output

class MyCommand(WestCommand):

    def __init__(self):
        super().__init__(
            'my-command-name', # gets stored as self.name
            'one-line help for what my-command-name does', # self.help
            # self.description:
```

(continues on next page)

(continued from previous page)

```

    dedent('''
    A multi-line description of my-command.

    You can split this up into multiple paragraphs and they'll get
    reflowed for you. You can also pass
    formatter_class=argparse.RawDescriptionHelpFormatter when calling
    parser_adder.add_parser() below if you want to keep your line
    endings.''))

def do_add_parser(self, parser_adder):
    # This is a bit of boilerplate, which allows you full control over the
    # type of argparse handling you want. The "parser_adder" argument is
    # the return value of an argparse.ArgumentParser.add_subparsers() call.
    parser = parser_adder.add_parser(self.name,
                                     help=self.help,
                                     description=self.description)

    # Add some example options using the standard argparse module API.
    parser.add_argument('-o', '--optional', help='an optional argument')
    parser.add_argument('required', help='a required argument')

    return parser          # gets stored as self.parser

def do_run(self, args, unknown_args):
    # This gets called when the user runs the command, e.g.:
    #
    # $ west my-command-name -o FOO BAR
    # --optional is FOO
    # required is BAR
    log.info('--optional is', args.optional)
    log.info('required is', args.required)

```

You can ignore the second argument to `do_run()` (`unknown_args` above), as `WestCommand` will reject unknown arguments by default. If you want to be passed a list of unknown arguments instead, add `accepts_unknown_args=True` to the `super().__init__()` arguments.

**Step 2: Add or Update Your `west-commands.yml`** You now need to add a `west-commands.yml` file to your project which describes your extension to west.

Here is an example for the above class definition, assuming it's in `my_west_extension.py` at the project root directory:

```

west-commands:
- file: my_west_extension.py
  commands:
  - name: my-command-name
    class: MyCommand
    help: one-line help for what my-command-name does

```

The top level of this YAML file is a map with a `west-commands` key. The key's value is a sequence of "command descriptors". Each command descriptor gives the location of a file implementing west extensions, along with the names of those extensions, and optionally the names of the classes which define them (if not given, the `class` value defaults to the same thing as `name`).

Some information in this file is redundant with definitions in the Python code. This is because west won't import `my_west_extension.py` until the user runs `west my-command-name`, since:

- It allows users to run `west update` with a manifest from an untrusted source, then use other west

commands without your code being imported along the way. Since importing a Python module is shell-equivalent, this provides some peace of mind.

- It's a small optimization, since your code will only be imported if it is needed.

So, unless your command is explicitly run, west will just load the `west-commands.yml` file to get the basic information it needs to display information about your extension to the user in `west --help` output, etc.

If you have multiple extensions, or want to split your extensions across multiple files, your `west-commands.yml` will look something like this:

```
west-commands:
- file: my_west_extension.py
  commands:
    - name: my-command-name
      class: MyCommand
      help: one-line help for what my-command-name does
- file: another_file.py
  commands:
    - name: command2
      help: another cool west extension
    - name: a-third-command
      class: ThirdCommand
      help: a third command in the same file as command2
```

Above:

- `my_west_extension.py` defines extension `my-command-name` with class `MyCommand`
- `another_file.py` defines two extensions:
  1. `command2` with class `command2`
  2. `a-third-command` with class `ThirdCommand`

See the file `west-commands-schema.yml` in the [west repository](#) for a schema describing the contents of a `west-commands.yml`.

**Step 3: Update Your Manifest** Finally, you need to specify the location of the `west-commands.yml` you just edited in your west manifest. If your extension is in a project, add it like this:

```
manifest:
  # [... other contents ...]

  projects:
    - name: your-project
      west-commands: path/to/west-commands.yml
  # [... other projects ...]
```

Where `path/to/west-commands.yml` is relative to the root of the project. Note that the name `west-commands.yml`, while encouraged, is just a convention; you can name the file something else if you need to.

Alternatively, if your extension is in the manifest repository, just do the same thing in the manifest's `self` section, like this:

```
manifest:
  # [... other contents ...]

  self:
    west-commands: path/to/west-commands.yml
```

That's it; you can now run `west my-command-name`. Your command's name, help, and the project which contains its code will now also show up in the `west --help` output. If you share the updated repositories with others, they'll be able to use it, too.

### 8.20.10 Building, Flashing and Debugging

Zephyr provides several [west extension commands](#) for building, flashing, and interacting with Zephyr programs running on a board: `build`, `flash`, `debug`, `debugserver` and `attach`.

For information on adding board support for the flashing and debugging commands, see [Flash and debug support](#) in the board porting guide.

**Building:** `west build`

---

**Tip:** Run `west build -h` for a quick overview.

---

The `build` command helps you build Zephyr applications from source. You can use [west config](#) to configure its behavior.

Its default behavior tries to “do what you mean”:

- If there is a Zephyr build directory named `build` in your current working directory, it is incrementally re-compiled. The same is true if you run `west build` from a Zephyr build directory.
- Otherwise, if you run `west build` from a Zephyr application's source directory and no build directory is found, a new one is created and the application is compiled in it.

**Basics** The easiest way to use `west build` is to go to an application's root directory (i.e. the folder containing the application's `CMakeLists.txt`) and then run:

```
west build -b <BOARD>
```

Where `<BOARD>` is the name of the board you want to build for. This is exactly the same name you would supply to CMake if you were to invoke it with: `cmake -DBOARD=<BOARD>`.

---

**Tip:** You can use the [west boards](#) command to list all supported boards.

---

A build directory named `build` will be created, and the application will be compiled there after `west build` runs CMake to create a build system in that directory. If `west build` finds an existing build directory, the application is incrementally re-compiled there without re-running CMake. You can force CMake to run again with `--cmake`.

You don't need to use the `--board` option if you've already got an existing build directory; `west build` can figure out the board from the CMake cache. For new builds, the `--board` option, `BOARD` environment variable, or `build.board` configuration option are checked (in that order).

**Examples** Here are some `west build` usage examples, grouped by area.

**Forcing CMake to Run Again** To force a CMake re-run, use the `--cmake` (or `--c`) option:

```
west build -c
```

**Setting a Default Board** To configure `west build` to build for the `reel_board` by default:

```
west config build.board reel_board
```

(You can use any other board supported by Zephyr here; it doesn't have to be `reel_board`.)

**Setting Source and Build Directories** To set the application source directory explicitly, give its path as a positional argument:

```
west build -b <BOARD> path/to/source/directory
```

To set the build directory explicitly, use `--build-dir` (or `-d`):

```
west build -b <BOARD> --build-dir path/to/build/directory
```

To change the default build directory from `build`, use the `build.dir-fmt` configuration option. This lets you name build directories using format strings, like this:

```
west config build.dir-fmt "build/{board}/{app}"
```

With the above, running `west build -b reel_board samples/hello_world` will use build directory `build/reel_board/hello_world`. See [Configuration Options](#) for more details on this option.

**Setting the Build System Target** To specify the build system target to run, use `--target` (or `-t`).

For example, on host platforms with QEMU, you can use the `run` target to build and run the `hello_world` sample for the emulated `qemu_x86` board in one command:

```
west build -b qemu_x86 -t run samples/hello_world
```

As another example, to use `-t` to list all build system targets:

```
west build -t help
```

As a final example, to use `-t` to run the `pristine` target, which deletes all the files in the build directory:

```
west build -t pristine
```

**Pristine Builds** A *pristine* build directory is essentially a new build directory. All byproducts from previous builds have been removed.

To force `west build` make the build directory pristine before re-running CMake to generate a build system, use the `--pristine=always` (or `-p=always`) option.

Giving `--pristine` or `-p` without a value has the same effect as giving it the value `always`. For example, these commands are equivalent:

```
west build -p -b reel_board samples/hello_world
west build -p=always -b reel_board samples/hello_world
```

By default, `west build` applies a heuristic to detect if the build directory needs to be made pristine. This is the same as using `--pristine=auto`.

---

**Tip:** You can run `west config build.pristine always` to always do a pristine build, or `west config build.pristine never` to disable the heuristic. See the `west build` [Configuration Options](#) for details.

---

**Verbose Builds** To print the CMake and compiler commands run by `west build`, use the global `west` verbosity option, `-v`:

```
west -v build -b reel_board samples/hello_world
```

**One-Time CMake Arguments** To pass additional arguments to the CMake invocation performed by `west build`, pass them after a `--` at the end of the command line.

---

**Important:** Passing additional CMake arguments like this forces `west build` to re-run CMake, even if a build system has already been generated.

After using `--` once to generate the build directory, use `west build -d <build-dir>` on subsequent runs to do incremental builds.

---

For example, to use the Unix Makefiles CMake generator instead of Ninja (which `west build` uses by default), run:

```
west build -b reel_board -- -G'Unix Makefiles'
```

To use Unix Makefiles and set `CMAKE_VERBOSE_MAKEFILE` to ON:

```
west build -b reel_board -- -G'Unix Makefiles' -DCMAKE_VERBOSE_MAKEFILE=ON
```

Notice how the `--` only appears once, even though multiple CMake arguments are given. All command-line arguments to `west build` after a `--` are passed to CMake.

To set `DTC_OVERLAY_FILE` to `enable-modem.overlay`, using that file as a [devicetree overlay](#):

```
west build -b reel_board -- -DDTC_OVERLAY_FILE=enable-modem.overlay
```

To merge the `file.conf` Kconfig fragment into your build's `.config`:

```
west build -- -DOVERLAY_CONFIG=file.conf
```

**Permanent CMake Arguments** The previous section describes how to add CMake arguments for a single `west build` command. If you want to save CMake arguments for `west build` to use every time it generates a new build system instead, you should use the `build.cmake-args` configuration option. Whenever `west build` runs CMake to generate a build system, it splits this option's value according to shell rules and includes the results in the `cmake` command line.

Remember that, by default, `west build` **tries to avoid generating a new build system if one is present** in your build directory. Therefore, you need to either delete any existing build directories or do a [pristine build](#) after setting `build.cmake-args` to make sure it will take effect.

For example, to always enable `CMAKE_EXPORT_COMPILE_COMMANDS`, you can run:

```
west config build.cmake-args -- -DCMAKE_EXPORT_COMPILE_COMMANDS=ON
```

(The extra `--` is used to force the rest of the command to be treated as a positional argument. Without it, [west config](#) would treat the `-DVAR=VAL` syntax as a use of its `-D` option.)

To enable `CMAKE_VERBOSE_MAKEFILE`, so CMake always produces a verbose build system:

```
west config build.cmake-args -- -DCMAKE_VERBOSE_MAKEFILE=ON
```

To save more than one argument in `build.cmake-args`, use a single string whose value can be split into distinct arguments (`west build` uses the Python function `shlex.split()` internally to split the value).

For example, to enable both `CMAKE_EXPORT_COMPILE_COMMANDS` and `CMAKE_VERBOSE_MAKEFILE`:

```
west config build.cmake-args -- "-DCMAKE_EXPORT_COMPILE_COMMANDS=ON -DCMAKE_VERBOSE_
↪MAKEFILE=ON"
```

If you want to save your CMake arguments in a separate file instead, you can combine CMake's `-C <initial-cache>` option with `build.cmake-args`. For instance, another way to set the options used in the previous example is to create a file named `~/my-cache.cmake` with the following contents:

```
set(CMAKE_EXPORT_COMPILE_COMMANDS ON CACHE BOOL "")
set(CMAKE_VERBOSE_MAKEFILE ON CACHE BOOL "")
```

Then run:

```
west config build.cmake-args "-C ~/my-cache.cmake"
```

See the [cmake\(1\) manual page](#) and the [set\(\) command](#) documentation for more details.

**Build tool arguments** Use `-o` to pass options to the underlying build tool.

This works with both `ninja` (*the default*) and `make` based build systems.

For example, to pass `-dexplain` to `ninja`:

```
west build -o=-dexplain
```

As another example, to pass `--keep-going` to `make`:

```
west build -o=--keep-going
```

Note that using `-o=--foo` instead of `-o --foo` is required to prevent `--foo` from being treated as a `west` build option.

**Build parallelism** By default, `ninja` uses all of your cores to build, while `make` uses only one. You can control this explicitly with the `-j` option supported by both tools.

For example, to build with 4 cores:

```
west build -o=-j4
```

The `-o` option is described further in the previous section.

**Configuration Options** You can [configure](#) `west` build using these options.

Option	Description
<code>build.board</code>	String. If given, this the board used by <i>west build</i> when <code>--board</code> is not given and <code>BOARD</code> is unset in the environment.
<code>build.board_warn</code>	Boolean, default <code>true</code> . If <code>false</code> , disables warnings when <i>west build</i> can't figure out the target board.
<code>build.cmake-args</code>	String. If present, the value will be split according to shell rules and passed to CMake whenever a new build system is generated. See <a href="#">Permanent CMake Arguments</a> .
<code>build.dir-fmt</code>	String, default <code>build</code> . The build folder format string, used by <i>west</i> whenever it needs to create or locate a build folder. The currently available arguments are: <ul style="list-style-type: none"><li>• <code>board</code>: The board name</li><li>• <code>source_dir</code>: The relative path from the current working directory to the source directory. If the current working directory is inside the source directory this will be set to an empty string.</li><li>• <code>app</code>: The name of the source directory.</li></ul>
<code>build.generator</code>	String, default <code>Ninja</code> . The <a href="#">CMake Generator</a> to use to create a build system. (To set a generator for a single build, see the <a href="#">above example</a> )
<code>build.guess-dir</code>	String, instructs <i>west</i> whether to try to guess what build folder to use when <code>build.dir-fmt</code> is in use and not enough information is available to resolve the build folder name. Can take these values: <ul style="list-style-type: none"><li>• <code>never</code> (default): Never try to guess, bail out instead and require the user to provide a build folder with <code>-d</code>.</li><li>• <code>runners</code>: Try to guess the folder when using any of the 'runner' commands. These are typically all commands that invoke an external tool, such as <code>flash</code> and <code>debug</code>.</li></ul>
<code>build.pristine</code>	String. Controls the way in which <i>west build</i> may clean the build folder before building. Can take the following values: <ul style="list-style-type: none"><li>• <code>never</code> (default): Never automatically make the build folder pristine.</li><li>• <code>auto</code>: <i>west build</i> will automatically make the build folder pristine before building, if a build system is present and the build would fail otherwise (e.g. the user has specified a different board or application from the one previously used to make the build directory).</li><li>• <code>always</code>: Always make the build folder pristine before building, if a build system is present.</li></ul>

### Flashing: `west flash`

---

**Tip:** Run `west flash -h` for additional help.

---

**Basics** From a Zephyr build directory, re-build the binary and flash it to your board:

```
west flash
```

Without options, the behavior is the same as `ninja flash` (or `make flash`, etc.).

To specify the build directory, use `--build-dir` (or `-d`):

```
west flash --build-dir path/to/build/directory
```

If you don't specify the build directory, `west flash` searches for one in `build`, then the current working directory. If you set the `build.dir-fmt` configuration option (see [Setting Source and Build Directories](#)), `west flash` searches there instead of `build`.

**Choosing a Runner** If your board's Zephyr integration supports flashing with multiple programs, you can specify which one to use using the `--runner` (or `-r`) option. For example, if West flashes your board with `nrfjprog` by default, but it also supports JLink, you can override the default with:

```
west flash --runner jlink
```

You can override the default flash runner at build time by using the `BOARD_FLASH_RUNNER` CMake variable, and the debug runner with `BOARD_DEBUG_RUNNER`.

For example:

```
# Set the default runner to "jlink", overriding the board's
# usual default.
west build [...] -- -DBOARD_FLASH_RUNNER=jlink
```

See [One-Time CMake Arguments](#) and [Permanent CMake Arguments](#) for more information on setting CMake arguments.

See [Flash and debug runners](#) below for more information on the runner library used by West. The list of runners which support flashing can be obtained with `west flash -H`; if run from a build directory or with `--build-dir`, this will print additional information on available runners for your board.

**Configuration Overrides** The CMake cache contains default values West uses while flashing, such as where the board directory is on the file system, the path to the zephyr binaries to flash in several formats, and more. You can override any of this configuration at runtime with additional options.

For example, to override the HEX file containing the Zephyr image to flash (assuming your runner expects a HEX file), but keep other flash configuration at default values:

```
west flash --hex-file path/to/some/other.hex
```

The `west flash -h` output includes a complete list of overrides supported by all runners.

**Runner-Specific Overrides** Each runner may support additional options related to flashing. For example, some runners support an `--erase` flag, which mass-erases the flash storage on your board before flashing the Zephyr image.

To view all of the available options for the runners your board supports, as well as their usage information, use `--context` (or `-H`):

```
west flash --context
```

---

**Important:** Note the capital H in the short option name. This re-runs the build in order to ensure the information displayed is up to date!

---

When running West outside of a build directory, `west flash -H` just prints a list of runners. You can use `west flash -H -r <runner-name>` to print usage information for options supported by that runner.

For example, to print usage information about the `jlink` runner:

```
west flash -H -r jlink
```

**Debugging:** `west debug`, `west debugserver`

---

**Tip:** Run `west debug -h` or `west debugserver -h` for additional help.

---

**Basics** From a Zephyr build directory, to attach a debugger to your board and open up a debug console (e.g. a GDB session):

```
west debug
```

To attach a debugger to your board and open up a local network port you can connect a debugger to (e.g. an IDE debugger):

```
west debugserver
```

Without options, the behavior is the same as `ninja debug` and `ninja debugserver` (or `make debug`, etc.).

To specify the build directory, use `--build-dir` (or `-d`):

```
west debug --build-dir path/to/build/directory
west debugserver --build-dir path/to/build/directory
```

If you don't specify the build directory, these commands search for one in `build`, then the current working directory. If you set the `build.dir-fmt` configuration option (see [Setting Source and Build Directories](#)), `west debug` searches there instead of `build`.

**Choosing a Runner** If your board's Zephyr integration supports debugging with multiple programs, you can specify which one to use using the `--runner` (or `-r`) option. For example, if West debugs your board with `pyocd-gdbserver` by default, but it also supports JLink, you can override the default with:

```
west debug --runner jlink
west debugserver --runner jlink
```

See [Flash and debug runners](#) below for more information on the runner library used by West. The list of runners which support debugging can be obtained with `west debug -H`; if run from a build directory or with `--build-dir`, this will print additional information on available runners for your board.

**Configuration Overrides** The CMake cache contains default values West uses for debugging, such as where the board directory is on the file system, the path to the zephyr binaries containing symbol tables, and more. You can override any of this configuration at runtime with additional options.

For example, to override the ELF file containing the Zephyr binary and symbol tables (assuming your runner expects an ELF file), but keep other debug configuration at default values:

```
west debug --elf-file path/to/some/other.elf
west debugserver --elf-file path/to/some/other.elf
```

The `west debug -h` output includes a complete list of overrides supported by all runners.

**Runner-Specific Overrides** Each runner may support additional options related to debugging. For example, some runners support flags which allow you to set the network ports used by debug servers.

To view all of the available options for the runners your board supports, as well as their usage information, use `--context` (or `-H`):

```
west debug --context
```

(The command `west debugserver --context` will print the same output.)

---

**Important:** Note the capital H in the short option name. This re-runs the build in order to ensure the information displayed is up to date!

---

When running West outside of a build directory, `west debug -H` just prints a list of runners. You can use `west debug -H -r <runner-name>` to print usage information for options supported by that runner.

For example, to print usage information about the `jlink` runner:

```
west debug -H -r jlink
```

## Flash and debug runners

The flash and debug commands use Python wrappers around various [Flash & Debug Host Tools](#). These wrappers are all defined in a Python library at `scripts/west_commands/runners`. Each wrapper is called a *runner*. Runners can flash and/or debug Zephyr programs.

The central abstraction within this library is `ZephyrBinaryRunner`, an abstract class which represents runners. The set of available runners is determined by the imported subclasses of `ZephyrBinaryRunner`. `ZephyrBinaryRunner` is available in the `runners.core` module; individual runner implementations are in other submodules, such as `runners.nrfjprog`, `runners.openocd`, etc.

## Hacking

This section documents the `runners.core` module used by the flash and debug commands. This is the core abstraction used to implement support for these features.

**Warning:** These APIs are provided for reference, but they are more “shared code” used to implement multiple extension commands than a stable API.

Developers can add support for new ways to flash and debug Zephyr programs by implementing additional runners. To get this support into upstream Zephyr, the runner should be added into a new or existing runners module, and imported from `runners/__init__.py`.

---

**Note:** The test cases in `scripts/west_commands/tests` add unit test coverage for the runners package and individual runner classes.

Please try to add tests when adding new runners. Note that if your changes break existing test cases, CI testing on upstream pull requests will fail.

---

### Zephyr binary runner core interfaces

This provides the core `ZephyrBinaryRunner` class meant for public use, as well as some other helpers for concrete runner classes.

```
class runners.core.BuildConfiguration(build_dir: str)
```

This helper class provides access to build-time configuration.

Configuration options can be read as if the object were a dict, either `object['CONFIG_FOO']` or `object.get('CONFIG_FOO')`.

Kconfig configuration values are available (parsed from `.config`).

`getboolean(option)`

If a boolean option is explicitly set to y or n, returns its value. Otherwise, falls back to False.

`exception runners.core.MissingProgram(program)`

`FileNotFoundError` subclass for missing program dependencies.

No significant changes from the parent `FileNotFoundError`; this is useful for explicitly signaling that the file in question is a program that some class requires to proceed.

The filename attribute contains the missing program.

`class runners.core.NetworkPortHelper`

Helper class for dealing with local IP network ports.

`get_unused_ports(starting_from)`

Find unused network ports, starting at given values.

`starting_from` is an iterable of ports the caller would like to use.

The return value is an iterable of ports, in the same order, using the given values if they were unused, or the next sequentially available unused port otherwise.

Ports may be bound between this call's check and actual usage, so callers still need to handle errors involving returned ports.

`class runners.core.RunnerCaps(commands: Set[str] = {'attach', 'debug', 'debugserver', 'flash'},  
flash_addr: bool = False, erase: bool = False)`

This class represents a runner class's capabilities.

Each capability is represented as an attribute with the same name. Flag attributes are True or False.

Available capabilities:

- `commands`: set of supported commands; default is {'flash', 'debug', 'debugserver', 'attach'}.
- `flash_addr`: whether the runner supports flashing to an arbitrary address. Default is False. If true, the runner must honor the `-dt-flash` option.
- `erase`: whether the runner supports an `-erase` option, which does a mass-erase of the entire addressable flash on the target before flashing. On multi-core SoCs, this may only erase portions of flash specific the actual target core. (This option can be useful for things like clearing out old settings values or other subsystem state that may affect the behavior of the zephyr image. It is also sometimes needed by SoCs which have flash-like areas that can't be sector erased by the underlying tool before flashing; UICR on nRF SoCs is one example.)

`class runners.core.RunnerConfig(build_dir: str, board_dir: str, elf_file: Optional[str], hex_file:  
Optional[str], bin_file: Optional[str], gdb: Optional[str] = None,  
openocd: Optional[str] = None, openocd_search: List[str] = [])`

Runner execution-time configuration.

This is a common object shared by all runners. Individual runners can register specific configuration options using their `do_add_parser()` hooks.

`bin_file: Optional[str]`

Alias for field number 4

`board_dir: str`

Alias for field number 1

`build_dir: str`

Alias for field number 0

`elf_file: Optional[str]`

Alias for field number 2

`gdb:` `Optional[str]`  
Alias for field number 5

`hex_file:` `Optional[str]`  
Alias for field number 3

`openocd:` `Optional[str]`  
Alias for field number 6

`openocd_search:` `List[str]`  
Alias for field number 7

`class runners.core.ZephyrBinaryRunner(cfg: runners.core.RunnerConfig)`

Abstract superclass for binary runners (flashers, debuggers).

**Note:** this class's API has changed relatively rarely since it was added, but it is not considered a stable Zephyr API, and may change without notice.

With some exceptions, boards supported by Zephyr must provide generic means to be flashed (have a Zephyr firmware binary permanently installed on the device for running) and debugged (have a breakpoint debugger and program loader on a host workstation attached to a running target).

This is supported by four top-level commands managed by the Zephyr build system:

- ‘flash’: flash a previously configured binary to the board, start execution on the target, then return.
- ‘debug’: connect to the board via a debugging protocol, program the flash, then drop the user into a debugger interface with symbol tables loaded from the current binary, and block until it exits.
- ‘debugserver’: connect via a board-specific debugging protocol, then reset and halt the target. Ensure the user is now able to connect to a debug server with symbol tables loaded from the binary.
- ‘attach’: connect to the board via a debugging protocol, then drop the user into a debugger interface with symbol tables loaded from the current binary, and block until it exits. Unlike ‘debug’, this command does not program the flash.

This class provides an API for these commands. Every subclass is called a ‘runner’ for short. Each runner has a name (like ‘pyocd’), and declares commands it can handle (like ‘flash’). Boards (like ‘nrf52dk\_nrf52832’) declare which runner(s) are compatible with them to the Zephyr build system, along with information on how to configure the runner to work with the board.

The build system will then place enough information in the build directory to create and use runners with this class’s `create()` method, which provides a command line argument parsing API. You can also create runners by instantiating subclasses directly.

In order to define your own runner, you need to:

1. Define a `ZephyrBinaryRunner` subclass, and implement its abstract methods. You may need to override `capabilities()`.
2. Make sure the Python module defining your runner class is imported, e.g. by editing this package’s `__init__.py` (otherwise, `get_runners()` won’t work).
3. Give your runner’s name to the Zephyr build system in your board’s `board.cmake`.

Additional advice:

- If you need to import any non-standard-library modules, make sure to catch `ImportError` and defer complaints about it to a `RuntimeError` if one is missing. This avoids affecting users that don’t require your runner, while still making it clear what went wrong to users that do require it that don’t have the necessary modules installed.

- If you need to ask the user something (e.g. using `input()`), do it in your `create()` classmethod, not `do_run()`. That ensures your `__init__()` really has everything it needs to call `do_run()`, and also avoids calling `input()` when not instantiating within a command line application.
- Use `self.logger` to log messages using the standard library's logging API; your logger is named `"runner.<your-runner-name>"`

For command-line invocation from the Zephyr build system, runners define their own argparse-based interface through the common `add_parser()` (and runner-specific `do_add_parser()` it delegates to), and provide a way to create instances of themselves from a `RunnerConfig` and parsed runner-specific arguments via `create()`.

Runners use a variety of host tools and configuration values, the user interface to which is abstracted by this class. Each runner subclass should take any values it needs to execute one of these commands in its constructor. The actual command execution is handled in the `run()` method.

classmethod `add_parser(parser)`

Adds a sub-command parser for this runner.

The given object, `parser`, is a sub-command parser from the `argparse` module. For more details, refer to the documentation for `argparse.ArgumentParser.add_subparsers()`.

The lone common optional argument is:

- `-dt-flash` (if the runner capabilities includes `flash_addr`)

Runner-specific options are added through the `do_add_parser()` hook.

property `build_conf: runners.core.BuildConfiguration`

Get a `BuildConfiguration` for the build directory.

call(*cmd: List[str], \*\*kwargs*) → int

Subclass `subprocess.call()` wrapper.

Subclasses should use this method to run command in a subprocess and get its return code, rather than using `subprocess` directly, to keep accurate debug logs.

classmethod `capabilities()` → *runners.core.RunnerCaps*

Returns a `RunnerCaps` representing this runner's capabilities.

This implementation returns the default capabilities.

Subclasses should override appropriately if needed.

*cfg*

`RunnerConfig` for this instance.

`check_call(cmd: List[str], **kwargs)`

Subclass `subprocess.check_call()` wrapper.

Subclasses should use this method to run command in a subprocess and check that it executed correctly, rather than using `subprocess` directly, to keep accurate debug logs.

`check_output(cmd: List[str], **kwargs)` → bytes

Subclass `subprocess.check_output()` wrapper.

Subclasses should use this method to run command in a subprocess and check that it executed correctly, rather than using `subprocess` directly, to keep accurate debug logs.

classmethod `create(cfg: runners.core.RunnerConfig, args: argparse.Namespace)` → *runners.core.ZephyrBinaryRunner*

Create an instance from command-line arguments.

- `cfg`: runner configuration (pass to superclass `__init__`)
- `args`: arguments parsed from execution environment, as specified by `add_parser()`.

```

abstract classmethod do_add_parser(parser)
    Hook for adding runner-specific options.

abstract classmethod do_create(cfg: runners.core.RunnerConfig, args: argparse.Namespace)
    → runners.core.ZephyrBinaryRunner

    Hook for instance creation from command line arguments.

abstract do_run(command: str, **kwargs)
    Concrete runner; run() delegates to this. Implement in subclasses.

    In case of an unsupported command, raise a ValueError.

ensure_output(output_type: str) → None
    Ensure self.cfg has a particular output artifact.

    For example, ensure_output('bin') ensures that self.cfg.bin_file refers to an existing file. Errors
    out if it's missing or undefined.

    Parameters output_type – string naming the output type

static flash_address_from_build_conf(build_conf: runners.core.BuildConfiguration)
    If CONFIG_HAS_FLASH_LOAD_OFFSET is n in build_conf, return the CON-
    FIG_FLASH_BASE_ADDRESS value. Otherwise, return CONFIG_FLASH_BASE_ADDRESS +
    CONFIG_FLASH_LOAD_OFFSET.

static get_flash_address(args: argparse.Namespace, build_conf:
    runners.core.BuildConfiguration, default: int = 0) → int

    Helper method for extracting a flash address.

    If args.dt_flash is true, returns the address obtained from ZephyrBinaryRun-
    ner.flash_address_from_build_conf(build_conf).

    Otherwise (when args.dt_flash is False), the default value is returned.

static get_runners() → List[Type[runners.core.ZephyrBinaryRunner]]
    Get a list of all currently defined runner classes.

logger
    logging.Logger for this instance.

abstract classmethod name() → str
    Return this runner's user-visible name.

    When choosing a name, pick something short and lowercase, based on the name of the tool
    (like openocd, jlink, etc.) or the target architecture/board (like xtensa etc.).

popen_ignore_int(cmd: List[str]) → subprocess.Popen
    Spawn a child command, ensuring it ignores SIGINT.

    The returned subprocess.Popen object must be manually terminated.

static require(program: str) → str
    Require that a program is installed before proceeding.

    Parameters program – name of the program that is required, or path to a program
    binary.

    If program is an absolute path to an existing program binary, this call succeeds. Otherwise,
    try to find the program by name on the system PATH.

    If the program can be found, its path is returned. Otherwise, raises MissingProgram.

run(command: str, **kwargs)
    Runs command ('flash', 'debug', 'debugserver', 'attach').

    This is the main entry point to this runner.

```

`run_client(client)`

Run a client that handles SIGINT.

`run_server_and_client(server, client)`

Run a server that ignores SIGINT, and a client that handles it.

This routine portably:

- creates a Popen object for the server command which ignores SIGINT
- runs `client` in a subprocess while temporarily ignoring SIGINT
- cleans up the server after the client exits.

It's useful to e.g. open a GDB server and client.

`property thread_info_enabled: bool`

Returns True if `self.build_conf` has `CONFIG_DEBUG_THREAD_INFO` enabled. This supports the `CONFIG_OPENOCD_SUPPORT` fallback as well for now.

## Doing it By Hand

If you prefer not to use West to flash or debug your board, simply inspect the build directory for the binaries output by the build system. These will be named something like `zephyr/zephyr.elf`, `zephyr/zephyr.hex`, etc., depending on your board's build system integration. These binaries may be flashed to a board using alternative tools of your choice, or used for debugging as needed, e.g. as a source of symbol tables.

By default, these West commands rebuild binaries before flashing and debugging. This can of course also be accomplished using the usual targets provided by Zephyr's build system (in fact, that's how these commands do it).

### 8.20.11 Signing Binaries

The `west sign extension` command can be used to sign a Zephyr application binary for consumption by a bootloader using an external tool. Run `west sign -h` for command line help.

#### MCUboot / imgtool

The Zephyr build system has special support for signing binaries for use with the [MCUboot](#) bootloader using the [imgtool](#) program provided by its developers. You can both build and sign this type of application binary in one step by setting some Kconfig options. If you do, `west flash` will use the signed binaries.

If you use this feature, you don't need to run `west sign` yourself; the build system will do it for you.

Here is an example workflow, which builds and flashes MCUboot, as well as the `hello_world` application for chain-loading by MCUboot. Run these commands from the `zephyrproject` workspace you created in the [Getting Started Guide](#).

```
west build -b YOUR_BOARD -s bootloader/mcuboot/boot/zephyr -d build-mcuboot
west build -b YOUR_BOARD -s zephyr/samples/hello_world -d build-hello-signed -- \
  -DCONFIG_BOOTLOADER_MCUBOOT=y \
  -DCONFIG_MCUBOOT_SIGNATURE_KEY_FILE=\"bootloader/mcuboot/root-rsa-2048.pem\"

west flash -d build-mcuboot
west flash -d build-hello-signed
```

Notes on the above commands:

- `YOUR_BOARD` should be changed to match your board

- The `CONFIG_MCUBOOT_SIGNATURE_KEY_FILE` value is the insecure default provided and used by by MCUboot for development and testing
- You can change the `hello_world` application directory to any other application that can be loaded by MCUboot, such as the `smp_svr_sample`

For more information on these and other related configuration options, see:

- **`:kconfig: CONFIG_BOOTLOADER_MCUBOOT`**: build the application for loading by MCUboot
- **`:kconfig: CONFIG_MCUBOOT_SIGNATURE_KEY_FILE`**: the key file to use with `west sign`. If you have your own key, change this appropriately
- **`:kconfig: CONFIG_MCUBOOT_EXTRA_IMGTOOL_ARGS`**: optional additional command line arguments for `imgtool`
- **`:kconfig: CONFIG_MCUBOOT_GENERATE_CONFIRMED_IMAGE`**: also generate a confirmed image, which may be more useful for flashing in production environments than the OTA-able default image
- On Windows, if you get “Access denied” issues, the recommended fix is to run `pip3 install imgtool`, then retry with a pristine build directory.

If your `west flash runner` uses an image format supported by `imgtool`, you should see something like this on your device’s serial console when you run `west flash -d build-mcuboot`:

```
*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1 ***
[00:00:00.004,669] <inf> mcuboot: Starting bootloader
[00:00:00.011,169] <inf> mcuboot: Primary image: magic=unset, swap_type=0x1, copy_
↳done=0x3, image_ok=0x3
[00:00:00.021,636] <inf> mcuboot: Boot source: none
[00:00:00.027,313] <wrn> mcuboot: Failed reading image headers; Image=0
[00:00:00.035,064] <err> mcuboot: Unable to find bootable image
```

Then, you should see something like this when you run `west flash -d build-hello-signed`:

```
*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1 ***
[00:00:00.004,669] <inf> mcuboot: Starting bootloader
[00:00:00.011,169] <inf> mcuboot: Primary image: magic=unset, swap_type=0x1, copy_
↳done=0x3, image_ok=0x3
[00:00:00.021,636] <inf> mcuboot: Boot source: none
[00:00:00.027,374] <inf> mcuboot: Swap type: none
[00:00:00.115,142] <inf> mcuboot: Bootloader chainload address offset: 0xc000
[00:00:00.123,168] <inf> mcuboot: Jumping to the first image slot
*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1 ***
Hello World! nrf52840dk_nrf52840
```

Whether `west flash` supports this feature depends on your runner. The `nrfjprog` and `pyocd` runners work with the above flow. If your runner does not support this flow and you would like it to, please send a patch or file an issue for adding support.

## 8.20.12 Additional Zephyr extension commands

This page documents miscellaneous [Zephyr Extensions](#).

**Listing boards:** `west boards`

The `boards` command can be used to list the boards that are supported by Zephyr without having to resort to additional sources of information.

It can be run by typing:

```
west boards
```

This command lists all supported boards in a default format. If you prefer to specify the display format yourself you can use the `--format` (or `-f`) flag:

```
west boards -f "{arch}:{name}"
```

Additional help about the formatting options can be found by running:

```
west boards -h
```

### Installing CMake packages: `west zephyr-export`

This command registers the current Zephyr installation as a CMake config package in the CMake user package registry.

In Windows, the CMake user package registry is found in `HKEY_CURRENT_USER\Software\Kitware\CMake\Packages`.

In Linux and MacOS, the CMake user package registry is found in `~/.cmake/packages`.

You may run this command when setting up a Zephyr workspace. If you do, application `CMakeLists.txt` files that are outside of your workspace will be able to find the Zephyr repository with the following:

```
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
```

See [share/zephyr-package/cmake](#) for details.

### Software bill of materials: `west sdx`

This command generates SPDX 2.2 tag-value documents, creating relationships from source files to the corresponding generated build files. `SPDX-License-Identifier` comments in source files are scanned and filled into the SPDX documents.

To use this command:

1. Pre-populate a build directory `BUILD_DIR` like this:

```
west sdx --init -d BUILD_DIR
```

This step ensures the build directory contains CMake metadata required for SPDX document generation.

2. Build your application using this pre-created build directory, like so:

```
west build -d BUILD_DIR [...]
```

3. Generate SPDX documents using this build directory:

```
west sdx -d BUILD_DIR
```

This generates the following SPDX bill-of-materials (BOM) documents in `BUILD_DIR/spdx/`:

- `app.sdx`: BOM for the application source files used for the build
- `zephyr.sdx`: **BOM for the specific Zephyr source code files used for** the build
- `build.sdx`: BOM for the built output files

Each file in the bill-of-materials is scanned, so that its hashes (SHA256 and SHA1) can be recorded, along with any detected licenses if an `SPDX-License-Identifier` comment appears in the file.

SPDX Relationships are created to indicate dependencies between CMake build targets, build targets that are linked together, and source files that are compiled to generate the built library files.

`west spdx` accepts these additional options:

- `-n PREFIX`: a prefix for the Document Namespaces that will be included in the generated SPDX documents. See [SPDX specification 2.2 section 2.5](#) for details. If `-n` is omitted, a default namespace will be generated according to the default format described in section 2.5 using a random UUID.
- `-s SPDX_DIR`: specifies an alternate directory where the SPDX documents should be written instead of `BUILD_DIR/spdx/`.
- `--analyze-includes`: in addition to recording the compiled source code files (e.g. `.c`, `.S`) in the bills-of-materials, also attempt to determine the specific header files that are included for each `.c` file.

This takes longer, as it performs a dry run using the C compiler for each `.c` file using the same arguments that were passed to it for the actual build.

- `--include-sdk`: with `--analyze-includes`, also create a fourth SPDX document, `sdk.spdx`, which lists header files included from the SDK.

### 8.20.13 History and Motivation

West was added to the Zephyr project to fulfill two fundamental requirements:

- The ability to work with multiple Git repositories
- The ability to provide an extensible and user-friendly command-line interface for basic Zephyr workflows

During the development of west, a set of [Design Constraints](#) were identified to avoid the common pitfalls of tools of this kind.

#### Requirements

Although the motivation behind splitting the Zephyr codebase into multiple repositories is outside of the scope of this page, the fundamental requirements, along with a clear justification of the choice not to use existing tools and instead develop a new one, do belong here.

The basic requirements are:

- **R1**: Keep externally maintained code in separately maintained repositories outside of the main zephyr repository, without requiring users to manually clone each of the external repositories
- **R2**: Provide a tool that both Zephyr users and distributors can make use of to benefit from and extend
- **R3**: Allow users and downstream distributions to override or remove repositories without having to make changes to the zephyr repository
- **R4**: Support both continuous tracking and commit-based (bisectable) project updating

#### Rationale for a custom tool

Some of west's features are similar to those provided by [Git Submodules](#) and Google's [repo](#).

Existing tools were considered during west's initial design and development. None were found suitable for Zephyr's requirements. In particular, these were examined in detail:

- Google repo

- Does not cleanly support using zephyr as the manifest repository (**R4**)
- Python 2 only
- Does not play well with Windows
- Assumes Gerrit is used for code review
- Git submodules
  - Does not fully support **R1**, since the externally maintained repositories would still need to be inside the main zephyr Git tree
  - Does not support **R3**, since downstream copies would need to either delete or replace sub-module definitions
  - Does not support continuous tracking of the latest HEAD in external repositories (**R4**)
  - Requires hardcoding of the paths/locations of the external repositories

## Multiple Git Repositories

Zephyr intends to provide all required building blocks needed to deploy complex IoT applications. This in turn means that the Zephyr project is much more than an RTOS kernel, and is instead a collection of components that work together. In this context, there are a few reasons to work with multiple Git repositories in a standardized manner within the project:

- Clean separation of Zephyr original code and imported projects and libraries
- Avoidance of license incompatibilities between original and imported code
- Reduction in size and scope of the core Zephyr codebase, with additional repositories containing optional components instead of being imported directly into the tree
- Safety and security certifications
- Enforcement of modularization of the components
- Out-of-tree development based on subsets of the supported boards and SoCs

See [Basics](#) for information on how west workspaces manage multiple git repositories.

## Design Constraints

West is:

- **Optional:** it is always *possible* to drop back to “raw” command-line tools, i.e. use Zephyr without using west (although west itself might need to be installed and accessible to the build system). It may not always be *convenient* to do so, however. (If all of west’s features were already conveniently available, there would be no reason to develop it.)
- **Compatible with CMake:** building, flashing and debugging, and emulator support will always remain compatible with direct use of CMake.
- **Cross-platform:** West is written in Python 3, and works on all platforms supported by Zephyr.
- **Usable as a Library:** whenever possible, west features are implemented as libraries that can be used standalone in other programs, along with separate command line interfaces that wrap them. West itself is a Python package named `west`; its libraries are implemented as subpackages.
- **Conservative about features:** no features will be accepted without strong and compelling motivation.
- **Clearly specified:** West’s behavior in cases where it wraps other commands is clearly specified and documented. This enables interoperability with third party tools, and means Zephyr developers can always find out what is happening “under the hood” when using west.

See [Zephyr issue #6205](#) and for more details and discussion.

### 8.20.14 Moving to West

To convert a “pre-west” Zephyr setup on your computer to west, follow these steps. If you are starting from scratch, use the [Getting Started Guide](#) instead. See [Troubleshooting West](#) for advice on common issues.

1. Install west.

On Linux:

```
pip3 install --user -U west
```

On Windows and macOS:

```
pip3 install -U west
```

For details, see [Installing west](#).

2. Move your zephyr repository to a new zephyrproject parent directory, and change directory there.

On Linux and macOS:

```
mkdir zephyrproject
mv zephyr zephyrproject
cd zephyrproject
```

On Windows cmd.exe:

```
mkdir zephyrproject
move zephyr zephyrproject
chdir zephyrproject
```

The name `zephyrproject` is recommended, but you can choose any name with no spaces anywhere in the path.

3. Create a [west workspace](#) using the zephyr repository as a local manifest repository:

```
west init -l zephyr
```

This creates `zephyrproject/.west`, marking the root of your workspace, and does some other setup. It will not change the contents of the zephyr repository in any way.

4. Clone the rest of the repositories used by zephyr:

```
west update
```

**Make sure to run this command whenever you pull zephyr.** Otherwise, your local repositories will get out of sync. (Run `west list` for current information on these repositories.)

You are done: `zephyrproject` is now set up to use west.

### 8.20.15 Using Zephyr without west

This page provides information on using Zephyr without west. This is not recommended for beginners due to the extra effort involved. In particular, you will have to do work “by hand” to replace these features:

- cloning the additional source code repositories used by Zephyr in addition to the main zephyr repository, and keeping them up to date

- specifying the locations of these repositories to the Zephyr build system
- flashing and debugging without understanding detailed usage of the relevant host tools

---

**Note:** If you have previously installed west and want to stop using it, uninstall it first:

```
pip3 uninstall west
```

Otherwise, Zephyr’s build system will find it and may try to use it.

---

## Getting the Source

In addition to downloading the zephyr source code repository itself, you will need to manually clone the additional projects listed in the west manifest file inside that repository.

```
mkdir zephyrproject
cd zephyrproject
git clone https://github.com/zephyrproject-rtos/zephyr
# clone additional repositories listed in zephyr/west.yml,
# and check out the specified revisions as well.
```

As you pull changes in the zephyr repository, you will also need to maintain those additional repositories, adding new ones as necessary and keeping existing ones up to date at the latest revisions.

## Building applications

You can build a Zephyr application using CMake and Ninja (or make) directly without west installed if you specify any modules manually.

```
cmake -B build -GNinja -DZEPHYR_MODULES=module1;module2;... samples/hello_world
ninja -C build
```

When building with west installed, the Zephyr build system will use it to set [ZEPHYR\\_MODULES](#).

If you don’t have west installed and your application does not need any of these repositories, the build will still work.

If you don’t have west installed and your application *does* need one of these repositories, you must set ZEPHYR\_MODULES yourself as shown above.

See [Modules \(External projects\)](#) for more details.

## Flashing and Debugging

Running build system targets like `ninja flash`, `ninja debug`, etc. is just a call to the corresponding [west command](#). For example, `ninja flash` calls `west flash`<sup>1</sup>. If you don’t have west installed on your system, running those targets will fail. You can of course still flash and debug using any [Flash & Debug Host Tools](#) which work for your board (and which those west commands wrap).

If you want to use these build system targets but do not want to install west on your system using pip, it is possible to do so by manually creating a west workspace:

---

<sup>1</sup> Note that `west build` invokes `ninja`, among other tools. There’s no recursive invocation of either `west` or `ninja` involved by default, however, as `west build` does not invoke `ninja flash`, `debug`, etc. The one exception is if you specifically run one of these build system targets with a command line like `west build -t flash`. In that case, west is run twice: once for `west build`, and in a subprocess, again for `west flash`. Even in this case, `ninja` is only run once, as `ninja flash`. This is because these build system targets depend on an up to date build of the Zephyr application, so it’s compiled before `west flash` is run.

```
# cd into zephyrproject if not already there
git clone https://github.com/zephyrproject-rtos/west.git .west/west
```

Then create a file `.west/config` with the following contents:

```
[manifest]
path = zephyr

[zephyr]
base = zephyr
```

After that, and in order for `ninja` to be able to invoke `west` to flash and debug, you must specify the `west` directory. This can be done by setting the environment variable `WEST_DIR` to point to `zephyrproject/.west/west` before running `CMake` to set up a build directory.

For details on `west`'s Python APIs, see `west-apis`.

## 8.21 Optimizations

Guides on how to optimize Zephyr for performance, power and footprint.

### 8.21.1 Optimizing for Footprint

#### Stack Sizes

Stack sizes of various system threads are specified generously to allow for usage in different scenarios on as many supported platforms as possible. You should start the optimization process by reviewing all stack sizes and adjusting them for your application:

**:kconfig: `CONFIG\_ISR\_STACK\_SIZE`** Set to 2048 by default

**:kconfig: `CONFIG\_MAIN\_STACK\_SIZE`** Set to 1024 by default

**:kconfig: `CONFIG\_IDLE\_STACK\_SIZE`** Set to 320 by default

**:kconfig: `CONFIG\_SYSTEM\_WORKQUEUE\_STACK\_SIZE`** Set to 1024 by default

**:kconfig: `CONFIG\_PRIVILEGED\_STACK\_SIZE`** Set to 1024 by default, depends on userspace feature.

#### Unused Peripherals

Some peripherals are enabled by default. You can disable unused peripherals in your project configuration, for example:

```
CONFIG_GPIO=n
CONFIG_SPI=n
```

#### Various Debug/Informational Options

The following options are enabled by default to provide more information about the running application and to provide means for debugging and error handling:

**:kconfig: `CONFIG\_BOOT\_BANNER`** This option can be disabled to save a few bytes.

**:kconfig: `CONFIG\_DEBUG`** This option can be disabled for production builds

## MPU/MMU Support

Depending on your application and platform needs, you can disable MPU/MMU support to gain some memory and improve performance. Consider the consequences of this configuration choice though, because you'll lose advanced stack checking and support.

### 8.21.2 Optimization Tools

#### Footprint and Memory Usage

The build system offers 3 targets to view and analyse RAM, ROM and stack usage in generated images. The tools run on the final image and give information about size of symbols and code being used in both RAM and ROM. Additionally, with features available through the compiler, we can also generate worst-case stack usage analysis:

Tools that are available as build system targets:

**Build Target: puncover** This target uses a 3rd party tools called puncover which can be found [here](#). When this target is built, it will launch a local web server which will allow you to open a web client and browse the files and view their ROM, RAM and stack usage. Before you can use this target, you will have to install the puncover python module:

```
pip3 install git+https://github.com/HBehrens/puncover --user
```

Then:

Using west:

```
west build -b reel_board samples/hello_world
west build -t puncover
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsistem:
cmake -B build -GNinja -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
ninja -C build puncover
```

To view worst-case stack usage analysis, build this with the **:kconfig: `CONFIG\_STACK\_USAGE`** enabled.

Using west:

```
west build -b reel_board samples/hello_world -- -DCONFIG_STACK_USAGE=y
west build -t puncover
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsistem:
cmake -B build -GNinja -DBOARD=reel_board -DCONFIG_STACK_USAGE=y samples/hello_world

# Now run ninja on the generated build system:
ninja -C build puncover
```

**Build Target: ram\_report** List all compiled objects and their RAM usage in a tabular form with bytes per symbol and the percentage it uses. The data is grouped based on the file system location of the object in the tree and the file containing the symbol.

Use the `ram_report` target with your board:

Using west:

```
west build -b reel_board samples/hello_world
west build -t ram_report
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based builds system:
cmake -B build -GNinja -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
ninja -C build ram_report
```

which will generate something similar to the output below:

Path	Size	%
...		
...		
SystemCoreClock		
↪ 4	0.08%	
_kernel		
↪ 48	0.99%	
_sw_isr_table		
↪ 384	7.94%	
cli.10544		
↪ 16	0.33%	
gpio_initialized.9765		
↪ 1	0.02%

...
...

```

**Build Target: rom\_report** List all compiled objects and their ROM usage in a tabular form with bytes per symbol and the percentage it uses. The data is grouped based on the file system location of the object in the tree and the file containing the symbol.

Use the `rom_report` to get the ROM report:

Using west:

```

west build -b reel_board samples/hello_world
west build -t rom_report

```

Using CMake and ninja:

```

# Use cmake to configure a Ninja-based buildsistem:
cmake -B build -GNinja -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
ninja -C build rom_report

```

which will generate something similar to the output below:

```

Path

## Data Structures

**Build Target: pahole** Poke-a-hole (pahole) is an object-file analysis tool to find the size of the data structures, and the holes caused due to aligning the data elements to the word-size of the CPU by the compiler.

Poke-a-hole (pahole) must be installed prior to using this target. It can be obtained from <https://git.kernel.org/pub/scm/devel/pahole/pahole.git> and is available in the dwarves package in both fedora and ubuntu:

```
sudo apt-get install dwarves
```

or in fedora:

```
sudo dnf install dwarves
```

Using west:

```
west build -b reel_board samples/hello_world
west build -t pahole
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsysteem:
cmake -B build -GNinja -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
ninja -C build pahole
```

After running this target, pahole will output the results to the console:

```
/* Used at: zephyr/isr_tables.c */
/* <80> ../include/sw_isr_table.h:30 */
struct _isr_table_entry {
    void *                arg;                /*      0      4 */
    void                  (*isr)(void *);    /*      4      4 */

    /* size: 8, cachelines: 1, members: 2 */
    /* last cacheline: 8 bytes */
};
/* Used at: zephyr/isr_tables.c */
/* <eb> ../include/arch/arm/aarch32/cortex_m/mpu/arm_mpu_v7m.h:134 */
struct arm_mpu_region_attr {
    uint32_t              rasr;                /*      0      4 */

    /* size: 4, cachelines: 1, members: 1 */
    /* last cacheline: 4 bytes */
};
/* Used at: zephyr/isr_tables.c */
/* <112> ../include/arch/arm/aarch32/cortex_m/mpu/arm_mpu.h:24 */
struct arm_mpu_region {
    uint32_t              base;                /*      0      4 */
    const char *          name;                /*      4      4 */
    arm_mpu_region_attr_t attr;                /*      8      4 */

    /* size: 12, cachelines: 1, members: 3 */
    /* last cacheline: 12 bytes */
};
...
...
```

## 8.22 Zephyr CMake Package

The Zephyr CMake package is a convenient way to create a Zephyr-based application.

The Zephyr CMake package ensures that CMake can automatically select a Zephyr to use for building the application, whether it is a Zephyr repository application, Zephyr workspace application, or a Zephyr freestanding application.

When developing a Zephyr-based application, then a developer simply needs to write `find_package(Zephyr)` in the beginning of the application `CMakeLists.txt` file.

To use the Zephyr CMake package it must first be exported to the CMake user package registry. This is means creating a reference to the current Zephyr installation inside the CMake user package registry.

Ubuntu

In Linux, the CMake user package registry is found in:

```
~/ .cmake/package/Zephyr
```

macOS

In macOS, the CMake user package registry is found in:

```
~/ .cmake/package/Zephyr
```

Windows

In Windows, the CMake user package registry is found in:

```
HKEY_CURRENT_USER\Software\Kitware\CMake\Packages\Zephyr
```

The Zephyr CMake package allows CMake to automatically find a Zephyr base. One or more Zephyr installations must be exported. Exporting multiple Zephyr installations may be useful when developing or testing Zephyr freestanding applications, Zephyr workspace application with vendor forks, etc..

### 8.22.1 Zephyr CMake package export (west)

When installing Zephyr using `west` then it is recommended to export Zephyr using `west zephyr-export`.

### 8.22.2 Zephyr CMake package export (without west)

Zephyr CMake package is exported to the CMake user package registry using the following commands:

```
cmake -P <PATH-TO-ZEPHYR>/share/zephyr-package/cmake/zephyr_export.cmake
```

This will export the current Zephyr to the CMake user package registry.

To also export the Zephyr Unittest CMake package, run the following command in addition:

```
cmake -P <PATH-TO-ZEPHYR>/share/zephyrunittest-package/cmake/zephyr_export.cmake
```

### 8.22.3 Zephyr application structure

An application can be placed anywhere on your disk, but to better understand how the Zephyr package is used, we will name three specific layouts.

### Zephyr repository application

A Zephyr repository has the following structure:

```
<projects>/zephyr-workspace
├── zephyr
│   ├── arch
│   ├── boards
│   ├── cmake
│   ├── samples
│   │   ├── hello_world
│   │   └── ...
│   ├── tests
│   └── ...
```

Any application located inside this tree, is simply referred to as a Zephyr repository application. In this example `hello_world` is a Zephyr repository application.

### Zephyr workspace application

A Zephyr workspace has the following structure:

```
<projects>/zephyr-workspace
├── zephyr
├── bootloader
├── modules
├── tools
├── <vendor/private-repositories>
├── my_applications
│   └── my_first_app
```

Any application located in such workspace, but outside the Zephyr repository itself, is referred to as a Zephyr workspace application. In this example `my_first_app` is a Zephyr workspace application.

---

**Note:** The root of a Zephyr workspace is identical to `west topdir` if the workspace was installed using `west`

---

### Zephyr freestanding application

A Zephyr freestanding application is a Zephyr application located outside of a Zephyr workspace.

```
<projects>/zephyr-workspace
├── zephyr
├── bootloader
└── ...

<home>/app
├── CMakeLists.txt
├── prj.conf
├── src
│   └── main.c
```

In this example `app` is a Zephyr freestanding application.

### 8.22.4 Zephyr Base Environment Setting

The Zephyr CMake package search functionality allows for explicitly specifying a Zephyr base using an environment variable.

To do this, use the following `find_package()` syntax:

```
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
```

This syntax instructs CMake to first search for Zephyr using the Zephyr base environment setting `ZEPHYR_BASE` and then use the normal search paths.

### 8.22.5 Zephyr CMake Package Search Order

When Zephyr base environment setting is not used for searching, the Zephyr installation matching the following criteria will be used:

- A Zephyr repository application will use the Zephyr in which it is located. For example:

```
<projects>/zephyr-workspace/zephyr
├── samples
│   └── hello_world
```

in this example, `hello_world` will use `<projects>/zephyr-workspace/zephyr`.

- Zephyr workspace application will use the Zephyr that share the same workspace. For example:

```
<projects>/zephyr-workspace
├── zephyr
├── ...
└── my_applications
    └── my_first_app
```

in this example, `my_first_app` will use `<projects>/zephyr-workspace/zephyr` as this Zephyr is located in the same workspace as the Zephyr workspace application.

- Zephyr freestanding application will use the Zephyr registered in the CMake user package registry. For example:

```
<projects>/zephyr-workspace-1
├── zephyr                                     (Not exported to CMake)

<projects>/zephyr-workspace-2
├── zephyr                                     (Exported to CMake)

<home>/app
├── CMakeLists.txt
├── prj.conf
├── src
│   └── main.c
```

in this example, only `<projects>/zephyr-workspace-2/zephyr` is exported to the CMake package registry and therefore this Zephyr will be used by the Zephyr freestanding application `<home>/app`.

If user wants to test the application with `<projects>/zephyr-workspace-1/zephyr`, this can be done by using the Zephyr Base environment setting, meaning set `ZEPHYR_BASE=<projects>/zephyr-workspace-1/zephyr`, before running CMake.

**Note:** The Zephyr package selected on the first CMake invocation will be used for all subsequent builds. To change the Zephyr package, for example to test the application using Zephyr base

environment setting, then it is necessary to do a pristine build first (See [Rebuilding an Application](#)).

---

### 8.22.6 Zephyr CMake Package Version

When writing an application then it is possible to specify a Zephyr version number `x.y.z` that must be used in order to build the application.

Specifying a version is especially useful for a Zephyr freestanding application as it ensures the application is built with a minimal Zephyr version.

It also helps CMake to select the correct Zephyr to use for building, when there are multiple Zephyr installations in the system.

For example:

```
cmake_minimum_required(VERSION 3.13.1)
find_package(Zephyr 2.2.0)
project(app)
```

will require `app` to be built with Zephyr 2.2.0 as minimum. CMake will search all exported candidates to find a Zephyr installation which matches this version criteria.

Thus it is possible to have multiple Zephyr installations and have CMake automatically select between them based on the version number provided, see [CMake package version](#) for details.

For example:

```
<projects>/zephyr-workspace-2.a
└─ zephyr                      (Exported to CMake)

<projects>/zephyr-workspace-2.b
└─ zephyr                      (Exported to CMake)

<home>/app
├─ CMakeLists.txt
├─ prj.conf
├─ src
│   └─ main.c
```

in this case, there are two released versions of Zephyr installed at their own workspaces. Workspace 2.a and 2.b, corresponding to the Zephyr version.

To ensure `app` is built with minimum version 2.a the following `find_package` syntax may be used:

```
cmake_minimum_required(VERSION 3.13.1)
find_package(Zephyr 2.a)
project(app)
```

Note that both 2.a and 2.b fulfill this requirement.

CMake also supports the keyword `EXACT`, to ensure an exact version is used, if that is required. In this case, the application `CMakeLists.txt` could be written as:

```
cmake_minimum_required(VERSION 3.13.1)
find_package(Zephyr 2.a EXACT)
project(app)
```

In case no Zephyr is found which satisfies the version required, as example, the application specifies

```
cmake_minimum_required(VERSION 3.13.1)
find_package(Zephyr 2.z)
project(app)
```

then an error similar to below will be printed:

```
Could not find a configuration file for package "Zephyr" that is compatible
with requested version "2.z".
```

The following configuration files were considered but not accepted:

```
<projects>/zephyr-workspace-2.a/zephyr/share/zephyr-package/cmake/ZephyrConfig.
→ cmake, version: 2.a.0
<projects>/zephyr-workspace-2.b/zephyr/share/zephyr-package/cmake/ZephyrConfig.
→ cmake, version: 2.b.0
```

**Note:** It can also be beneficial to specify a version number for Zephyr repository applications and Zephyr workspace applications. Specifying a version in those cases ensures the application will only build if the Zephyr repository or workspace is matching. This can be useful to avoid accidental builds when only part of a workspace has been updated.

### 8.22.7 Multiple Zephyr Installations (Zephyr workspace)

Testing out a new Zephyr version, while at the same time keeping the existing Zephyr in the workspace untouched is sometimes beneficial.

Or having both an upstream Zephyr, Vendor specific, and a custom Zephyr in same workspace.

For example:

```
<projects>/zephyr-workspace
├── zephyr
├── zephyr-vendor
├── zephyr-custom
├── ...
└── my_applications
    └── my_first_app
```

in this setup, `find_package(Zephyr)` has the following order of precedence for selecting which Zephyr to use:

- Project name: `zephyr`
- First project, when Zephyr projects are ordered lexicographical, in this case.
  - `zephyr-custom`
  - `zephyr-vendor`

This means that `my_first_app` will use `<projects>/zephyr-workspace/zephyr`.

It is possible to specify a Zephyr preference list in the application.

A Zephyr preference list can be specified as:

```
cmake_minimum_required(VERSION 3.13.1)

set(ZEPHYR_PREFER "zephyr-custom" "zephyr-vendor")
find_package(Zephyr)
```

(continues on next page)

(continued from previous page)

```
project(my_first_app)
```

the ZEPHYR\_PREFER is a list, allowing for multiple Zephyrs. If a Zephyr is specified in the list, but not found in the system, it is simply ignored and `find_package(Zephyr)` will continue to the next candidate.

This allows for temporary creation of a new Zephyr release to be tested, without touching current Zephyr. When testing is done, the `zephyr-test` folder can simply be removed. Such a `CMakeLists.txt` could look as:

```
cmake_minimum_required(VERSION 3.13.1)

set(ZEPHYR_PREFER "zephyr-test")
find_package(Zephyr)

project(my_first_app)
```

### 8.22.8 Zephyr Build Configuration CMake package

The Zephyr Build Configuration CMake package provides a possibility for a Zephyr based project to control Zephyr build settings in a generic way.

It is similar to the use of `.zephyrrc` but with the possibility to automatically allow all users to share the build configuration through the project repository. But it also allows more advanced use cases than a `.zephyrrc`-file, such as loading of additional CMake boilerplate code.

The Zephyr Build Configuration CMake package will be loaded in the Zephyr boilerplate code after initial properties and `ZEPHYR_BASE` has been defined, but before CMake code execution. This allows the Zephyr Build Configuration CMake package to setup or extend properties such as: `DTS_ROOT`, `BOARD_ROOT`, `TOOLCHAIN_ROOT` / other toolchain setup, fixed overlays, and any other property that can be controlled. It also allows inclusion of additional boilerplate code.

To provide a Zephyr Build Configuration CMake package, create `ZephyrBuildConfig.cmake` and place it in a Zephyr workspace top-level folder as:

```
<projects>/zephyr-workspace
├── zephyr
├── ...
└── zephyr application (can be named anything)
    └── share/zephyrbuid-package/cmake/ZephyrBuildConfig.cmake
```

The Zephyr Build Configuration CMake package will not search in any CMake default search paths, and thus cannot be installed in the CMake package registry. There will be no version checking on the Zephyr Build Configuration package.

---

**Note:** `share/zephyrbuid-package/cmake/ZephyrBuildConfig.cmake` follows the same folder structure as the Zephyr CMake package.

It is possible to place `ZephyrBuildConfig.cmake` directly in a `<zephyr application>/cmake` folder or another folder, as long as that folder is honoring the [CMake package search](#) algorithm.

---

A sample `ZephyrBuildConfig.cmake` can be seen below.

```
# ZephyrBuildConfig.cmake sample code

# To ensure final path is absolute and does not contain ../.. in variable.
get_filename_component(APPLICATION_PROJECT_DIR
```

(continues on next page)

(continued from previous page)

```

        ${CMAKE_CURRENT_LIST_DIR}/../../../../
        ABSOLUTE
    )

    # Add this project to list of board roots
    list(APPEND BOARD_ROOT ${APPLICATION_PROJECT_DIR})

    # Default to GNU Arm Embedded toolchain if no toolchain is set
    if(NOT ENV{ZEPHYR_TOOLCHAIN_VARIANT})
        set(ZEPHYR_TOOLCHAIN_VARIANT gnuarmemb)
        find_program(GNU_ARM_GCC arm-none-eabi-gcc)
        if(NOT ${GNU_ARM_GCC} STREQUAL GNU_ARM_GCC-NOTFOUND)
            # The toolchain root is located above the path to the compiler.
            get_filename_component(GNUARMEMB_TOOLCHAIN_PATH ${GNU_ARM_GCC}/../.. ABSOLUTE)
        endif()
    endif()
endif()

```

### 8.22.9 Zephyr Build Configuration CMake package (Freestanding application)

The Zephyr Build Configuration CMake package can be located outside a Zephyr workspace, for example located with a [Zephyr freestanding application](#).

Create the build configuration as described in the previous section, and then refer to the location of your Zephyr Build Configuration CMake package using the CMake variable `ZephyrBuildConfiguration_ROOT`.

1. At the CMake command line, like this:

```
cmake -DZephyrBuildConfiguration_ROOT=<path-to-build-config> ...
```

2. At the top of your application's top level `CMakeLists.txt`, like this:

```
set(ZephyrBuildConfiguration_ROOT <path-to-build-config>)
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})

```

If you choose this option, make sure to set the variable **before** calling `find_package(Zephyr ...)`, as shown above.

3. In a separate CMake script which is pre-loaded to populate the CMake cache, like this:

```

# Put this in a file with a name like "zephyr-settings.cmake"
set(ZephyrBuildConfiguration_ROOT <path-to-build-config>
    CACHE STRING "pre-cached build config"
)

```

You can tell the build system to use this file by adding `-C zephyr-settings.cmake` to your CMake command line. This principle is useful when not using `west` as both this setting and Zephyr modules can be specified using the same file. See Zephyr module [Without West](#).

### 8.22.10 Zephyr CMake package source code

The Zephyr CMake package source code in `<PATH-TO-ZEPHYR>/share/zephyr-package/cmake` contains the CMake config package which is used by CMake `find_package` function.

It also contains code for exporting Zephyr as a CMake config package.

The following is an overview of those files

`CMakeLists.txt` The `CMakeLists.txt` file for the CMake build system which is responsible for exporting Zephyr as a package to the CMake user package registry.

`ZephyrConfigVersion.cmake` The Zephyr package version file. This file is called by CMake to determine if this installation fulfils the requirements specified by user when calling `find_package(Zephyr . .)`. It is also responsible for detection of Zephyr repository or workspace only installations.

`ZephyrUnittestConfigVersion.cmake` Same responsibility as `ZephyrConfigVersion.cmake`, but for unit tests. Includes `ZephyrConfigVersion.cmake`.

`ZephyrConfig.cmake` The Zephyr package file. This file is called by CMake to for the package meeting which fulfils the requirements specified by user when calling `find_package(Zephyr ...)`. This file is responsible for sourcing of boilerplate code.

`ZephyrUnittestConfig.cmake` Same responsibility as `ZephyrConfig.cmake`, but for unit tests. Includes `ZephyrConfig.cmake`.

`zephyr_package_search.cmake` Common file used for detection of Zephyr repository and workspace candidates. Used by `ZephyrConfigVersion.cmake` and `ZephyrConfig.cmake` for common code.

`pristine.cmake` Pristine file for removing all files created by CMake during configure and generator time when exporting Zephyr CMake package. Running `pristine` keeps all package related files mentioned above.

# Chapter 9

## Security

These documents describe the requirements, processes, and developer guidelines for ensuring security is addressed within the Zephyr project.

### 9.1 Zephyr Security Overview

#### 9.1.1 Introduction

This document outlines the steps of the Zephyr Security Subcommittee towards a defined security process that helps developers build more secure software while addressing security compliance requirements. It presents the key ideas of the security process and outlines which documents need to be created. After the process is implemented and all supporting documents are created, this document is a top-level overview and entry point.

#### Overview and Scope

We begin with an overview of the Zephyr development process, which mainly focuses on security functionality.

In subsequent sections, the individual parts of the process are treated in detail. As depicted in Figure 1, these main steps are:

1. **Secure Development:** Defines the system architecture and development process that ensures adherence to relevant coding principles and quality assurance procedures.
2. **Secure Design:** Defines security procedures and implement measures to enforce them. A security architecture of the system and relevant sub-modules is created, threats are identified, and counter-measures designed. Their correct implementation and the validity of the threat models are checked by code reviews. Finally, a process shall be defined for reporting, classifying, and mitigating security issues..
3. **Security Certification:** Defines the certifiable part of the Zephyr RTOS. This includes an evaluation target, its assets, and how these assets are protected. Certification claims shall be determined and backed with appropriate evidence.

#### Intended Audience

This document is a guideline for the development of a security process by the Zephyr Security Subcommittee and the Zephyr Technical Steering Committee. It provides an overview of the Zephyr security process for (security) engineers and architects.

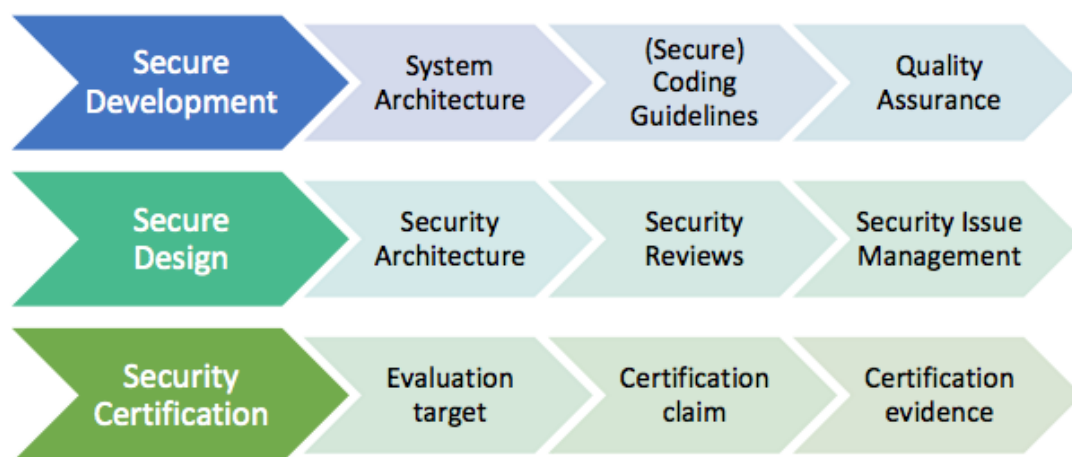

Fig. 1: Figure 1. Security Process Steps

## Nomenclature

In this document, the keywords “MUST”, “MUST NOT”, “REQUIRED”, “SHALL”, “SHALL NOT”, “SHOULD”, “SHOULD NOT”, “RECOMMENDED”, “MAY”, and “OPTIONAL” are to be interpreted as described in [?].

These words are used to define absolute requirements (or prohibitions), highly recommended requirements, and truly optional requirements. As noted in RFC-2119, “These terms are frequently used to specify behavior with security implications. The effects on security of not implementing a MUST or SHOULD, or doing something the specification says MUST NOT or SHOULD NOT be done may be very subtle. Document authors should take the time to elaborate the security implications of not following recommendations or requirements as most implementors will not have had the benefit of the experience and discussion that produced the specification.”

## Security Document Update

This document is a living document. As new requirements, features, and changes are identified, they will be added to this document through the following process:

1. Changes will be submitted from the interested party(ies) via pull requests to the Zephyr documentation repository.
2. The Zephyr Security Subcommittee will review these changes and provide feedback or acceptance of the changes.
3. Once accepted, these changes will become part of the document.

### 9.1.2 Current Security Definition

This section recapitulates the current status of secure development within the Zephyr RTOS. Currently, focus is put on functional security and code quality assurance, although additional security features are scoped.

The three major security measures currently implemented are:

- **Security Functionality** with a focus on cryptographic algorithms and protocols. Support for cryptographic hardware is scoped for future releases. The Zephyr runtime architecture is a monolithic binary and removes the need for dynamic loaders, thereby reducing the exposed attack surface.

- **Quality Assurance** is driven by using a development process that requires all code to be reviewed before being committed to the common repository. Furthermore, the reuse of proven building blocks such as network stacks increases the overall quality level and guarantees stable APIs. Static code analyses are provided by Coverity Scan.
- **Execution Protection** including thread separation, stack and memory protection is currently available in the upstream Zephyr RTOS starting with version 1.9.0 (stack protection). Memory protection and thread separation was added in version 1.10.0 for X86 and in version 1.11.0 for ARM and ARC.

These topics are discussed in more detail in the following subsections.

## Security Functionality

The security functionality in Zephyr hinges mainly on the inclusion of cryptographic algorithms, and on its monolithic system design.

The cryptographic features are provided through a set of cryptographic libraries. Applications can choose TinyCrypt2 or mbedTLS based on their needs. TinyCrypt2 supports key cryptographic algorithms required by the connectivity stacks. Tinycrypt2, however, only provides a limited set of algorithms. mbedTLS supports a wider range of algorithms, but at the cost of additional requirements such as malloc support. Applications can choose the solution that matches their individual requirements. Future work may include APIs to abstract the underlying crypto library choice.

APIs for vendor specific cryptographic IPs in both hardware and software are planned, including secure key storage in the form of secure access modules (SAMs), Trusted Platform Modules (TPMs), and Trusted Execution Environments (TEEs).

The security architecture is based on a monolithic design where the Zephyr kernel and all applications are compiled into a single static binary. System calls are implemented as function calls without requiring context switches. Static linking eliminates the potential for dynamically loading malicious code.

Additional protection features are available in later releases. Stack protection mechanisms are provided to protect against stack overruns. In addition, applications can take advantage of thread separation features to split the system into privileged and unprivileged execution environments. Memory protection features provide the capability to partition system resources (memory, peripheral address space, etc) and assign resources to individual threads or groups of threads. Stack, thread execution level, and memory protection constraints are enforced at the time of context switch.

## Quality Assurance

The Zephyr project uses an automated quality assurance process. The goal is to have a process including mandatory code reviews, feature and issue management/tracking, and static code analyses.

Code reviews are documented and enforced using a voting system before getting checked into the repository by the responsible subsystem's maintainer. The main goals of the code review are:

- Verifying correct functionality of the implementation
- Increasing the readability and maintainability of the contributed source code
- Ensuring appropriate usage of string and memory functions
- Validation of the user input
- Reviewing the security relevant code for potential issues

The current coding principles focus mostly on coding styles and conventions. Functional correctness is ensured by the build system and the experience of the reviewer. Especially for security relevant code, concrete and detailed guidelines need to be developed and aligned with the developers (see: [Secure Coding](#)).

Static code analyses are run on the Zephyr code tree on a regular basis using the open source Coverity Scan tool. Coverity Scan now includes complexity analysis.

Bug and issue tracking and management is performed using Jira. The term “survivability” was coined to cover pro-active security tasks such as security issue categorization and management. Initial effort has been started on the definition of vulnerability categorization and mitigation processes within Jira.

Issues determined by Coverity should have more stringent reviews before they are closed as non issues (at least another person educated in security processes need to agree on non-issue before closing).

A security subcommittee has been formed to develop a security process in more detail; this document is part of that process.

### Execution Protection

Execution protection is supported and can be categorized into the following tasks:

- **Memory separation:** Memory will be partitioned into regions and assigned attributes based on the owner of that region of memory. Threads will only have access to regions they control.
- **Stack protection:** Stack guards would provide mechanisms for detecting and trapping stack overruns. Individual threads should only have access to their own stacks.
- **Thread separation:** Individual threads should only have access to their own memory resources. As threads are scheduled, only memory resources owned by that thread will be accessible. Topics such as program flow protection and other measures for tamper resistance are currently not in scope.

### System Level Security (Ecosystem, ...)

System level security encompasses a wide variety of categories. Some examples of these would be:

- Secure/trusted boot
- Over the air (OTA) updates
- External Communication
- Device authentication
- Access control of onboard resources
  - Flash updating
  - Secure storage
  - Peripherals
- Root of trust
- Reduction of attack surface

Some of these categories are interconnected and rely on multiple pieces to be in place to produce a full solution for the application.

### 9.1.3 Secure Development Process

The development of secure code shall adhere to certain criteria. These include coding guidelines and development processes that can be roughly separated into two categories related to software quality and related to software security. Furthermore, a system architecture document shall be created and kept up-to-date with future development.

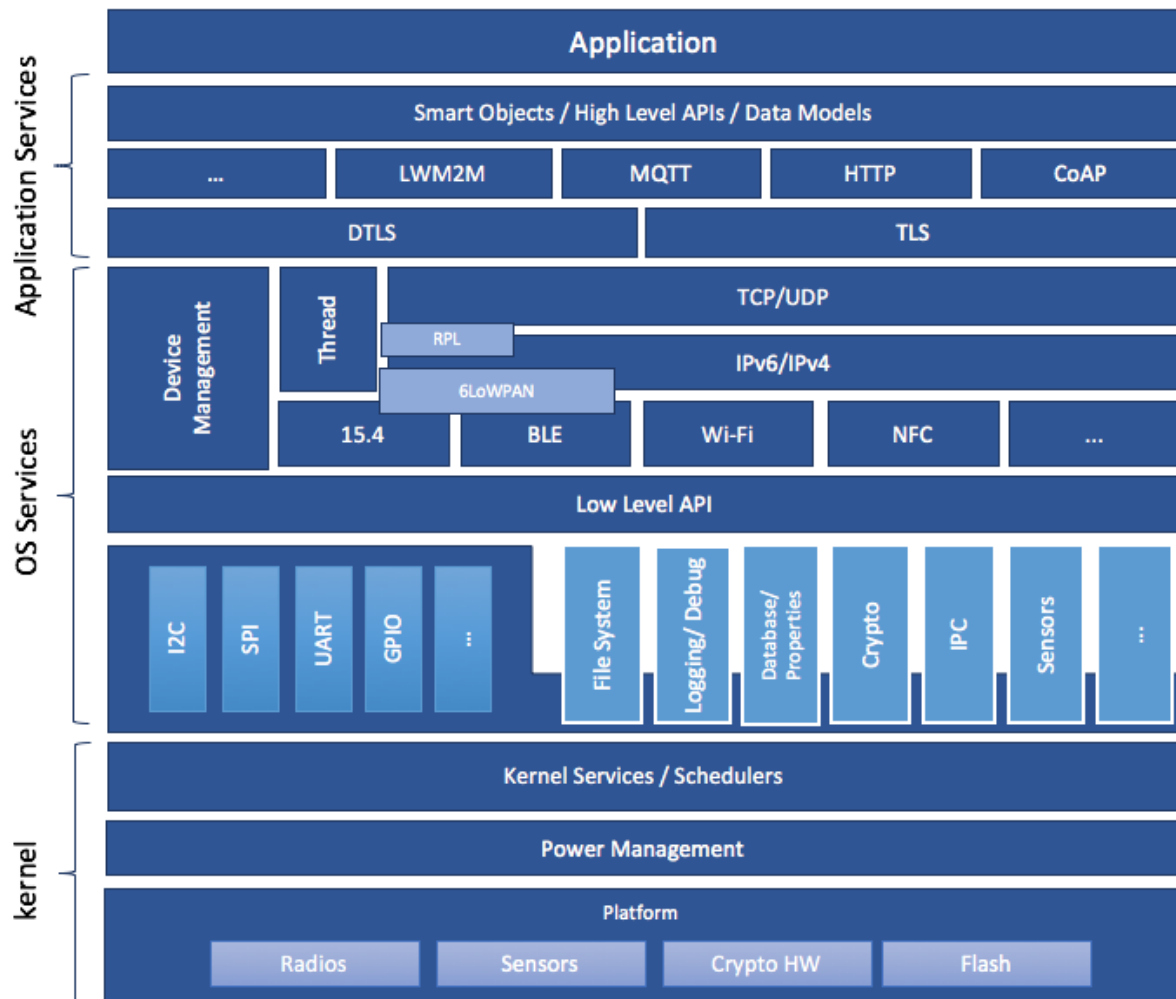

Fig. 2: Figure 2: Zephyr System Architecture

## System Architecture

A high-level schematic of the Zephyr system architecture is given in Figure 2. It separates the architecture into an OS part (*kernel + OS Services*) and a user-specific part (*Application Services*). The OS part itself contains low-level, platform specific drivers and the generic implementation of I/O APIs, file systems, kernel-specific functions, and the cryptographic library.

A document describing the system architecture and design choices shall be created and kept up to date with future development. This document shall include the base architecture of the Zephyr OS and an overview of important submodules. For each of the modules, a dedicated architecture document shall be created and evaluated against the implementation. These documents shall serve as an entry point to new developers and as a basis for the security architecture. Please refer to the [Zephyr subsystem documentation](#) for detailed information.

## Secure Coding

Designing an open software system such as Zephyr to be secure requires adhering to a defined set of design standards. These standards are included in the Zephyr Project documentation, specifically in its [Secure Coding](#) section. In [?], the following, widely accepted principles for protection mechanisms are defined to prevent security violations and limit their impact:

- **Open design** as a design principle incorporates the maxim that protection mechanisms cannot be kept secret on any system in widespread use. Instead of relying on secret, custom-tailored security measures, publicly accepted cryptographic algorithms and well established cryptographic libraries shall be used.
- **Economy of mechanism** specifies that the underlying design of a system shall be kept as simple and small as possible. In the context of the Zephyr project, this can be realized, e.g., by modular code [?] and abstracted APIs.
- **Complete mediation** requires that each access to every object and process needs to be authenticated first. Mechanisms to store access conditions shall be avoided if possible.
- **Fail-safe defaults** defines that access is restricted by default and permitted only in specific conditions defined by the system protection scheme, e.g., after successful authentication. Furthermore, default settings for services shall be chosen in a way to provide maximum security. This corresponds to the “Secure by Default” paradigm [?].
- **Separation of privilege** is the principle that two conditions or more need to be satisfied before access is granted. In the context of the Zephyr project, this could encompass split keys [?].
- **Least privilege** describes an access model in which each user, program and thread shall have the smallest possible subset of permissions in the system required to perform their task. This positive security model aims to minimize the attack surface of the system.
- **Least common mechanism** specifies that mechanisms common to more than one user or process shall not be shared if not strictly required. The example given in [?] is a function that should be implemented as a shared library executed by each user and not as a supervisor procedure shared by all users.
- **Psychological acceptability** requires that security features are easy to use by the developers in order to ensure its usage and the correctness of its application.

In addition to these general principles, the following points are specific to the development of a secure RTOS:

- **Complementary Security/Defense in Depth:** do not rely on a single threat mitigation approach. In case of the complementary security approach, parts of the threat mitigation are performed by the underlying platform. In case such mechanisms are not provided by the platform, or are not trusted, a defense in depth [?] paradigm shall be used.
- **Less commonly used services off by default:** to reduce the exposure of the system to potential attacks, features or services shall not be enabled by default if they are only rarely used (a threshold

of 80% is given in [?]). For the Zephyr project, this can be realized using the configuration management. Each functionality and module shall be represented as a configuration option and needs to be explicitly enabled. Then, all features, protocols, and drivers not required for a particular use case can be disabled. The user shall be notified if low-level options and APIs are enabled but not used by the application.

- **Change management:** to guarantee a traceability of changes to the system, each change shall follow a specified process including a change request, impact analysis, ratification, implementation, and validation phase. In each stage, appropriate documentation shall be provided. All commits shall be related to a bug report or change request in the issue tracker. Commits without a valid reference shall be denied.

Based on these design principles and commonly accepted best practices, a secure development guide shall be developed, published, and implemented into the Zephyr development process. Further details on this are given in the [Secure Design](#) section.

## Quality Assurance

The quality assurance part encompasses the following criteria:

- **Adherence to the Coding Conventions** with respect to coding style, naming schemes of modules, functions, variables, and so forth. This increases the readability of the Zephyr code base and eases the code review. These coding conventions are enforced by automated scripts prior to check-in.
- **Adherence to Deployment Guidelines** is required to ensure consistent releases with a well-documented feature set and a trackable list of security issues.
- **Code Reviews** ensure the functional correctness of the code base and shall be performed on each proposed code change prior to check-in. Code reviews shall be performed by at least one independent reviewer other than the author(s) of the code change. These reviews shall be performed by the subsystem maintainers and developers on a functional level and are to be distinguished from security reviews as laid out in the [Secure Design](#) section. Refer to the [Development and Contribution Process](#) documentation for more information.
- **Static Code Analysis** tools efficiently detect common coding mistakes in large code bases. All code shall be analyzed using an appropriate tool prior to merges into the main repository. This is not per individual commit, but is to be run on some interval on specific branches. It is mandatory to remove all findings or waive potential false-positives before each release. Waivers shall be documented centrally and in the form of a comment inside the source code itself. The documentation shall include the employed tool and its version, the date of the analysis, the branch and parent revision number, the reason for the waiver, the author of the respective code, and the approver(s) of the waiver. This shall as a minimum run on the main release branch and on the security branch. It shall be ensured that each release has zero issues with regard to static code analysis (including waivers). Refer to the [Development and Contribution Process](#) documentation for more information.
- **Complexity Analyses** shall be performed as part of the development process and metrics such as cyclomatic complexity shall be evaluated. The main goal is to keep the code as simple as possible.
- **Automation:** the review process and checks for coding rule adherence are a mandatory part of the precommit checks. To ensure consistent application, they shall be automated as part of the precommit procedure. Prior to merging large pieces of code in from subsystems, in addition to review process and coding rule adherence, all static code analysis must have been run and issues resolved.

## Release and Lifecycle Management

Lifecycle management contains several aspects:

- **Device management** encompasses the possibility to update the operating system and/or security related sub-systems of Zephyr enabled devices in the field.

- **Lifecycle management:** system stages shall be defined and documented along with the transactions between the stages in a system state diagram. For security reasons, this shall include locking of the device in case an attack has been detected, and a termination if the end of life is reached.
- **Release management** describes the process of defining the release cycle, documenting releases, and maintaining a record of known vulnerabilities and mitigations. Especially for certification purposes the integrity of the release needs to be ensured in a way that later manipulation (e.g. inserting of backdoors, etc.) can be easily detected.
- **Rights management and NDAs:** if required by the chosen certification, the confidentiality and integrity of the system needs to be ensured by an appropriate rights management (e.g. separate source code repository) and non-disclosure agreements between the relevant parties. In case of a repository shared between several parties, measures shall be taken that no malicious code is checked in.

These points shall be evaluated with respect to their impact on the development process employed for the Zephyr project.

### 9.1.4 Secure Design

In order to obtain a certifiable system or product, the security process needs to be clearly defined and its application needs to be monitored and driven. This process includes the development of security related modules in all of its stages and the management of reported security issues. Furthermore, threat models need to be created for currently known and future attack vectors, and their impact on the system needs to be investigated and mitigated. Please refer to the [Secure Coding](#) outlined in the Zephyr project documentation for detailed information.

The software security process includes:

- **Adherence to the Secure Development Coding** is mandatory to avoid that individual components breach the system security and to minimize the vulnerability of individual modules. While this can be partially achieved by automated tests, it is inevitable to investigate the correct implementation of security features such as countermeasures manually in security-critical modules.
- **Security Reviews** shall be performed by a security architect in preparation of each security-targeted release and each time a security-related module of the Zephyr project is changed. This process includes the validation of the effectiveness of implemented security measures, the adherence to the global security strategy and architecture, and the preparation of audits towards a security certification if required.
- **Security Issue Management** encompasses the evaluation of potential system vulnerabilities and their mitigation as described in [Security Issue Management](#).

These criteria and tasks need to be integrated into the development process for secure software and shall be automated wherever possible. On system level, and for each security related module of the secure branch of Zephyr, a directly responsible security architect shall be defined to guide the secure development process.

### Security Architecture

The general guidelines above shall be accompanied by an architectural security design on system- and module-level. The high level considerations include

- The identification of **security and compliance requirements**
- **Functional security** such as the use of cryptographic functions whenever applicable
- Design of **countermeasures** against known attack vectors
- Recording of security relevant **auditable events**
- Support for **Trusted Platform Modules (TPM)** and **Trusted Execution Environments (TEE)**

- Mechanisms to allow for **in-the-field updates** of devices using Zephyr
- Task scheduler and separation

The security architecture development is based on assets derived from the structural overview of the overall system architecture. Based on this, the individual steps include:

1. **Identification of assets** such as user data, authentication and encryption keys, key generation data (obtained from RNG), security relevant status information.
2. **Identification of threats** against the assets such as breaches of confidentiality, manipulation of user data, etc.
3. **Definition of requirements** regarding security and protection of the assets, e.g. countermeasures or memory protection schemes.

The security architecture shall be harmonized with the existing system architecture and implementation to determine potential deviations and mitigate existing weaknesses. Newly developed sub-modules that are integrated into the secure branch of the Zephyr project shall provide individual documents describing their security architecture. Additionally, their impact on the system level security shall be considered and documented.

## Security Vulnerability Reporting

Please see [Security Vulnerability Reporting](#) for information on reporting security vulnerabilities.

## Threat Modeling and Mitigation

The modeling of security threats against the Zephyr RTOS is required for the development of an accurate security architecture and for most certification schemes. The first step of this process is the definition of assets to be protected by the system. The next step then models how these assets are protected by the system and which threats against them are present. After a threat has been identified, a corresponding threat model is created. This model contains the asset and system vulnerabilities, as well as the description of the potential exploits of these vulnerabilities. Additionally, the impact on the asset, the module it resides in, and the overall system is to be estimated. This threat model is then considered in the module and system security architecture and appropriate counter-measures are defined to mitigate the threat or limit the impact of exploits.

In short, the threat modeling process can be separated into these steps (adapted from [?]):

1. Definition of assets
2. Application decomposition and creation of appropriate data flow diagrams (DFDs)
3. Threat identification and categorization using the [?] and [?] approaches
4. Determination of countermeasures and other mitigation approaches

This procedure shall be carried out during the design phase of modules and before major changes of the module or system architecture. Additionally, new models shall be created or existing ones shall be updated whenever new vulnerabilities or exploits are discovered. During security reviews, the threat models and the mitigation techniques shall be evaluated by the responsible security architect.

From these threat models and mitigation techniques tests shall be derived that prove the effectiveness of the countermeasures. These tests shall be integrated into the continuous integration workflow to ensure that the security is not impaired by regressions.

## Vulnerability Analyses

In order to find weak spots in the software implementation, vulnerability analyses (VA) shall be performed. Of special interest are investigations on cryptographic algorithms, critical OS tasks, and connectivity protocols.

On a pure software level, this encompasses

- **Penetration testing** of the RTOS on a particular hardware platform, which involves testing the respective Zephyr OS configuration and hardware as one system.
- **Side channel attacks** (timing invariance, power invariance, etc.) should be considered. For instance, ensuring **timing invariance** of the cryptographic algorithms and modules is required to reduce the attack surface. This applies to both the software implementations and when using cryptographic hardware.
- **Fuzzing tests** shall be performed on both exposed APIs and protocols.

The list given above serves primarily illustration purposes. For each module and for the complete Zephyr system (in general on a particular hardware platform), a suitable VA plan shall be created and executed. The findings of these analyses shall be considered in the security issue management process, and learnings shall be formulated as guidelines and incorporated into the secure coding guide.

If possible (as in case of fuzzing analyses), these tests shall be integrated into the continuous integration process.

### 9.1.5 Security Certification

One goal of creating a secure branch of the Zephyr RTOS is to create a certifiable system or certifiable submodules thereof. The certification scope and scheme is yet to be decided. However, many certification such as Common Criteria [?] require evidence that the evaluation claims are indeed fulfilled, so a general certification process is outlined in the following. Based on the final choices for the certification scheme and evaluation level, this process needs to be refined.

#### Generic Certification Process

In general, the steps towards a certification or precertification (compare [?]) are:

1. The **definition of assets** to be protected within the Zephyr RTOS. Potential candidates are confidential information such as cryptographic keys, user data such as communication logs, and potentially IP of the vendor or manufacturer.
2. Developing a **threat model** and **security architecture** to protect the assets against exploits of vulnerabilities of the system. As a complete threat model includes the overall product including the hardware platform, this might be realized by a split model containing a precertified secure branch of Zephyr which the vendor could use to certify their Zephyr-enabled product.
3. Formulating an **evaluation target** that includes the **certification claims** on the security of the assets to be evaluated and certified, as well as assumptions on the operating conditions.
4. Providing **proof** that the claims are fulfilled. This includes consistent documentation of the security development process, etc.

These steps are partially covered in previous sections as well. In contrast to these sections, the certification process only requires to consider those components that shall be covered by the certification. The security architecture, for example, considers assets on system level and might include items not relevant for the certification.

#### Certification Options

For the security certification as such, the following options can be pursued:

1. **Abstract precertification of Zephyr as a pure software system:** this option requires assumptions on the underlying hardware platform and the final application running on top of Zephyr. If these assumptions are met by the hardware and the application, a full certification can be more easily achieved. This option is the most flexible approach but puts the largest burden on the product vendor.

2. **Certification of Zephyr on specific hardware platform without a specific application in mind:** this scenario describes the enablement of a secure platform running the Zephyr RTOS. The hardware manufacturer certifies the platform under defined assumptions on the application. If these are met, the final product can be certified with little effort.
3. **Certification of an actual product:** in this case, a full product including a specific hardware, the Zephyr RTOS, and an application is certified.

In all three cases, the certification scheme (e.g. FIPS 140-2 [?] or Common Criteria [?]), the scope of the certification (main-stream Zephyr, security branch, or certain modules), and the certification/assurance level need to be determined.

In case of partial certifications (options 1 and 2), assumptions on hardware and/or software are required for certifications. These can include [?]

- **Appropriate physical security** of the hardware platform and its environment.
- **Sufficient protection of storage and timing channels** on the hardware platform itself and all connected devices. (No mentioning of remote connections.)
- Only **trusted/assured applications** running on the device
- The device and its software stack is configured and operated by **properly trained and trusted individuals** with no malicious intent.

These assumptions shall be part of the security claim and evaluation target documents.

## 9.2 Security Vulnerability Reporting

### 9.2.1 Introduction

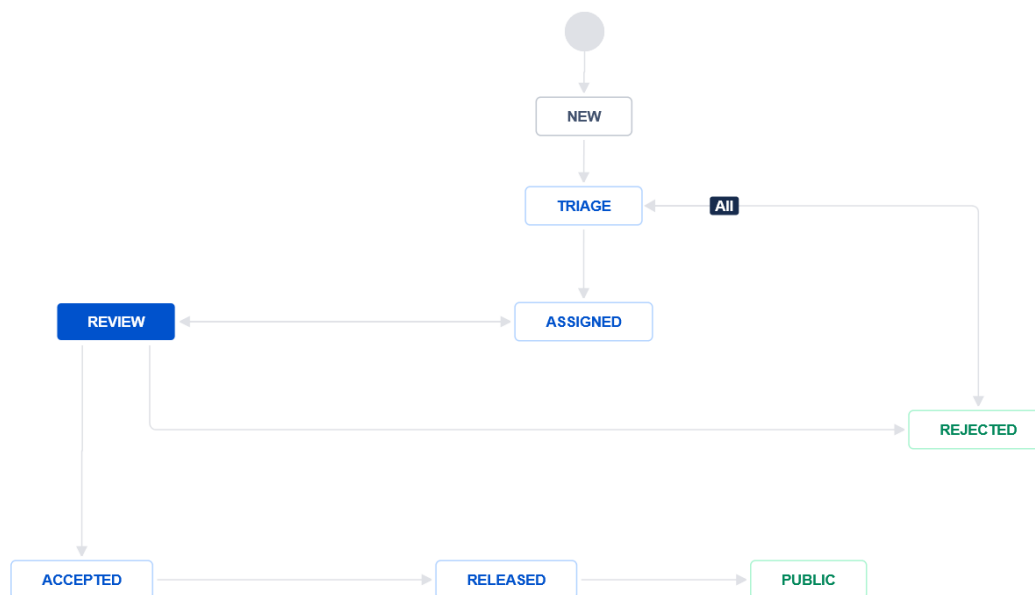

Vulnerabilities to the Zephyr project may be reported via email to the [vulnerabilities@zephyrproject.org](mailto:vulnerabilities@zephyrproject.org) mailing list. These reports will be acknowledged and analyzed by the security response team within 1 week. Each vulnerability will be entered into the Zephyr Project security tracking [JIRA](#). The original submitter will be granted permission to view the issues that they have reported.

Reporters may also submit reports by directly submitting them to the Zephyr Product security tracking [JIRA](#).

### 9.2.2 Security Issue Management

Issues within this bug tracking system will transition through a number of states according to this diagram:

- **New:** This state represents new reports that have been entered directly by a reporter. When entered by the response team in response to an email, the issue shall be transitioned directly to Triage.
- **Triage:** This issue is awaiting Triage by the response team. The response team will analyze the issue, determine a responsible entity, assign the JIRA ticket to that individual, and move the issue to the Assigned state. Part of triage will be to set the issue's priority.
- **Assigned:** The issue has been assigned, and is awaiting a fix by the assignee.
- **Review:** Once there is a Zephyr pull request for the issue, the PR link will be added to a comment in the issue, and the issue moved to the Review state.
- **Accepted:** Indicates that this issue has been merged into the appropriate branch within Zephyr.
- **Release:** The PR has been included in a released version of Zephyr.
- **Public:** The embargo period has ended. The issue will be made publicly visible, the associated CVE updated, and the vulnerabilities page in the docs updated to include the detailed information.

The issues created in this JIRA instance are kept private, due to the sensitive nature of security reports. The issues are only visible to certain parties:

- Members of the PSIRT mailing list
- the reporter
- others, as proposed and ratified by the Zephyr Security Subcommittee. In the general case, this will include:
  - The code owner responsible for the fix.
  - The Zephyr release owners for the relevant releases affected by this vulnerability.

The Zephyr Security Subcommittee shall review the reported vulnerabilities during any meeting with more than three people in attendance. During this review, they shall determine if new issues need to be embargoed.

The guideline for embargo will be based on: 1. Severity of the issue, and 2. Exploitability of the issue. Issues that the subcommittee decides do not need an embargo will be reproduced in the regular Zephyr project bug tracking system, and a comment added to the JIRA issue pointing to the bug tracking issue. These issues will be marked as being tracked within the Zephyr bug tracking system.

Security sensitive vulnerabilities shall be made public after an embargo period of at most 90 days. The intent is to allow 30 days within the Zephyr project to fix the issues, and 60 days for external parties building products using Zephyr to be able to apply and distribute these fixes.

Fixes to the code shall be made through pull requests PR in the Zephyr project github. Developers shall make an attempt to not reveal the sensitive nature of what is being fixed, and shall not refer to CVE numbers that have been assigned to the issue. The developer instead should merely describe what has been fixed.

The security subcommittee will maintain information mapping embargoed CVEs to these PRs (this information is within the JIRA issues), and produce regular reports of the state of security issues.

Each JIRA issue that is considered a security vulnerability shall be assigned a CVE number. As fixes are created, it may be necessary to allocate additional CVE numbers, or to retire numbers that were assigned.

### 9.2.3 Vulnerability Notification

Each Zephyr release shall contain a report of CVEs that were fixed in that release. Because of the sensitive nature of these vulnerabilities, the release shall merely include a list of CVEs that have been fixed. After the embargo period, the vulnerabilities page shall be updated to include additional details of these vulnerabilities. The vulnerability page shall give credit to the reporter(s) unless a reporter specifically requests anonymity.

The Zephyr project shall maintain a vulnerability-alerts mailing list. This list will be seeded initially with a contact from each project member. Additional parties can request to join this list by filling out the form at the [Vulnerability Registry](#). These parties will be vetted by the project director to determine that they have a legitimate interest in knowing about security vulnerabilities during the embargo period.

Periodically, the security subcommittee will send information to this mailing list describing known embargoed issues, and their backport status within the project. This information is intended to allow them to determine if they need to backport these changes to any internal trees.

When issues have been triaged, this list will be informed of:

- The Zephyr Project security JIRA link (ZEPSEC).
- The CVE number assigned.
- The subsystem involved.
- The severity of the issue.

After acceptance of a PR fixing the issue (merged), in addition to the above, the list will be informed of:

- The association between the CVE number and the PR fixing it.
- Backport plans within the Zephyr project.

### 9.2.4 Backporting of Security Vulnerabilities

Each security issue fixed within zephyr shall be backported to the following releases:

- The current Long Term Stable (LTS) release.
- The most recent two releases.

The developer of the fix shall be responsible for any necessary backports, and apply them to any of the above listed release branches, unless the fix does not apply (the vulnerability was introduced after this release was made).

Backports will be tracked on the security JIRA instance using a subtask issue of type “backport”.

### 9.2.5 Need to Know

Due to the sensitive nature of security vulnerabilities, it is important to share details and fixes only with those parties that have a need to know. The following parties will need to know details about security vulnerabilities before the embargo period ends:

- Maintainers will have access to all information within their domain area only.
- The current release manager, and the release manager for historical releases affected by the vulnerability (see backporting above).
- The Project Security Incident Response (PSIRT) team will have full access to information. The PSIRT is made up of representatives from platinum members, and volunteers who do work on triage from other members.
- As needed, release managers and maintainers may be invited to attend additional security meetings to discuss vulnerabilities.

## 9.3 Secure Coding

Traditionally, microcontroller-based systems have not placed much emphasis on security. They have usually been thought of as isolated, disconnected from the world, and not very vulnerable, just because of the difficulty in accessing them. The Internet of Things has changed this. Now, code running on small microcontrollers often has access to the internet, or at least to other devices (that may themselves have vulnerabilities). Given the volume they are often deployed at, uncontrolled access can be devastating<sup>1</sup>.

This document describes the requirements and process for ensuring security is addressed within the Zephyr project. All code submitted should comply with these principles.

Much of this document comes from [?].

### 9.3.1 Introduction and Scope

This document covers guidelines for the [Zephyr Project](#), from a security perspective. Many of the ideas contained herein are captured from other open source efforts.

We begin with an overview of secure design as it relates to Zephyr. This is followed by a section on [Secure development knowledge](#), which gives basic requirements that a developer working on the project will need to have. This section gives references to other security documents, and full details of how to write secure software are beyond the scope of this document. This section also describes vulnerability knowledge that at least one of the primary developers should have. This knowledge will be necessary for the review process described below this.

Following this is a description of the review process used to incorporate changes into the Zephyr code-base. This is followed by documentation about how security-sensitive issues are handled by the project.

Finally, the document covers how changes are to be made to this document.

### 9.3.2 Secure Coding

Designing an open software system such as Zephyr to be secure requires adhering to a defined set of design standards. In [?], the following, widely accepted principles for protection mechanisms are defined to help prevent security violations and limit their impact:

- **Open design** as a design guideline incorporates the maxim that protection mechanisms cannot be kept secret on any system in widespread use. Instead of relying on secret, custom-tailored security measures, publicly accepted cryptographic algorithms and well established cryptographic libraries shall be used.
- **Economy of mechanism** specifies that the underlying design of a system shall be kept as simple and small as possible. In the context of the Zephyr project, this can be realized, e.g., by modular code [?] and abstracted APIs.
- **Complete mediation** requires that each access to every object and process needs to be authenticated first. Mechanisms to store access conditions shall be avoided if possible.
- **Fail-safe defaults** defines that access is restricted by default and permitted only in specific conditions defined by the system protection scheme, e.g., after successful authentication. Furthermore, default settings for services shall be chosen in a way to provide maximum security. This corresponds to the “Secure by Default” paradigm [?].
- **Separation of privilege** is the principle that two conditions or more need to be satisfied before access is granted. In the context of the Zephyr project, this could encompass split keys [?].
- **Least privilege** describes an access model in which each user, program, and thread, shall have the smallest possible subset of permissions in the system required to perform their task. This positive security model aims to minimize the attack surface of the system.

---

<sup>1</sup> An [attack](#) resulted in a significant portion of DNS infrastructure being taken down.

- **Least common mechanism** specifies that mechanisms common to more than one user or process shall not be shared if not strictly required. The example given in [?] is a function that should be implemented as a shared library executed by each user and not as a supervisor procedure shared by all users.
- **Psychological acceptability** requires that security features are easy to use by the developers in order to ensure their usage and the correctness of its application.

In addition to these general principles, the following points are specific to the development of a secure RTOS:

- **Complementary Security/Defense in Depth:** do not rely on a single threat mitigation approach. In case of the complementary security approach, parts of the threat mitigation are performed by the underlying platform. In case such mechanisms are not provided by the platform, or are not trusted, a defense in depth [?] paradigm shall be used.
- **Less commonly used services off by default:** to reduce the exposure of the system to potential attacks, features or services shall not be enabled by default if they are only rarely used (a threshold of 80% is given in [?]). For the Zephyr project, this can be realized using the configuration management. Each functionality and module shall be represented as a configuration option and needs to be explicitly enabled. Then, all features, protocols, and drivers not required for a particular use case can be disabled. The user shall be notified if low-level options and APIs are enabled but not used by the application.
- **Change management:** to guarantee a traceability of changes to the system, each change shall follow a specified process including a change request, impact analysis, ratification, implementation, and validation phase. In each stage, appropriate documentation shall be provided. All commits shall be related to a bug report or change request in the issue tracker. Commits without a valid reference shall be denied.

### 9.3.3 Secure development knowledge

#### Secure designer

The Zephyr project must have at least one primary developer who knows how to design secure software.

This requires understanding the following design principles, including the 8 principles from [?]:

- economy of mechanism (keep the design as simple and small as practical, e.g., by adopting sweeping simplifications)
- fail-safe defaults (access decisions shall deny by default, and projects' installation shall be secure by default)
- complete mediation (every access that might be limited must be checked for authority and be non-bypassable)
- open design (security mechanisms should not depend on attacker ignorance of its design, but instead on more easily protected and changed information like keys and passwords)
- separation of privilege (ideally, access to important objects should depend on more than one condition, so that defeating one protection system won't enable complete access. For example, multi-factor authentication, such as requiring both a password and a hardware token, is stronger than single-factor authentication)
- least privilege (processes should operate with the least privilege necessary)
- least common mechanism (the design should minimize the mechanisms common to more than one user and depended on by all users, e.g., directories for temporary files)
- psychological acceptability (the human interface must be designed for ease of use - designing for "least astonishment" can help)

- limited attack surface (the set of the different points where an attacker can try to enter or extract data)
- input validation with whitelists (inputs should typically be checked to determine if they are valid before they are accepted; this validation should use whitelists (which only accept known-good values), not blacklists (which attempt to list known-bad values)).

## Vulnerability Knowledge

A “primary developer” in a project is anyone who is familiar with the project’s code base, is comfortable making changes to it, and is acknowledged as such by most other participants in the project. A primary developer would typically make a number of contributions over the past year (via code, documentation, or answering questions). Developers would typically be considered primary developers if they initiated the project (and have not left the project more than three years ago), have the option of receiving information on a private vulnerability reporting channel (if there is one), can accept commits on behalf of the project, or perform final releases of the project software. If there is only one developer, that individual is the primary developer.

At least one of the primary developers **must** know of common kinds of errors that lead to vulnerabilities in this kind of software, as well as at least one method to counter or mitigate each of them.

Examples (depending on the type of software) include SQL injection, OS injection, classic buffer overflow, cross-site scripting, missing authentication, and missing authorization. See the [CWE/SANS top 25](#) or [OWASP Top 10](#) for commonly used lists.

## Zephyr Security Subcommittee

There shall be a “Zephyr Security Subcommittee”, responsible for enforcing this guideline, monitoring reviews, and improving these guidelines.

This team will be established according to the Zephyr Project charter.

### 9.3.4 Code Review

The Zephyr project shall use a code review system that all changes are required to go through. Each change shall be reviewed by at least one primary developer that is not the author of the change. This developer shall determine if this change affects the security of the system (based on their general understanding of security), and if so, shall request the developer with vulnerability knowledge, or the secure designer to also review the code. Any of these individuals shall have the ability to block the change from being merged into the mainline code until the security issues have been addressed.

### 9.3.5 Issues and Bug Tracking

The Zephyr project shall have an issue tracking system (such as [JIRA](#)) that can be used to record and track defects that are found in the system.

Because security issues are often sensitive, this issue tracking system shall have a field to indicate a security issue. Setting this field shall result in the issue only being visible to the Zephyr Security Subcommittee. In addition, there shall be a field to allow the Zephyr Security Subcommittee to add additional users that will have visibility to a given issue.

This embargo, or limited visibility, shall only be for a fixed duration, with a default being a project-decided value. However, because security considerations are often external to the Zephyr project itself, it may be necessary to increase this embargo time. The time necessary shall be clearly annotated in the issue itself.

The list of issues shall be reviewed at least once a month by the Zephyr Security Subcommittee. This review should focus on tracking the fixes, determining if any external parties need to be notified or

involved, and determining when to lift the embargo on the issue. The embargo should **not** be lifted via an automated means, but the review team should avoid unnecessary delay in lifting issues that have been resolved.

### 9.3.6 Modifications to This Document

Changes to this document shall be reviewed by the Zephyr Security Subcommittee, and approved by consensus.

## 9.4 Sensor Device Threat Model

This document describes a threat model for an IoT sensor device. Spelling out a threat model helps direct development effort, and can be used to help prioritize these efforts as well.

This device contains a sensor of some type (for example temperature, or a pressure in a pipe), which sends this data to an SoC running a microcontroller. This microcontroller connects to a cloud service, and relays this sensor data to this service. The cloud service is also able to send configuration data to the device, as well as software update images. A general diagram can be seen in Figure 1:

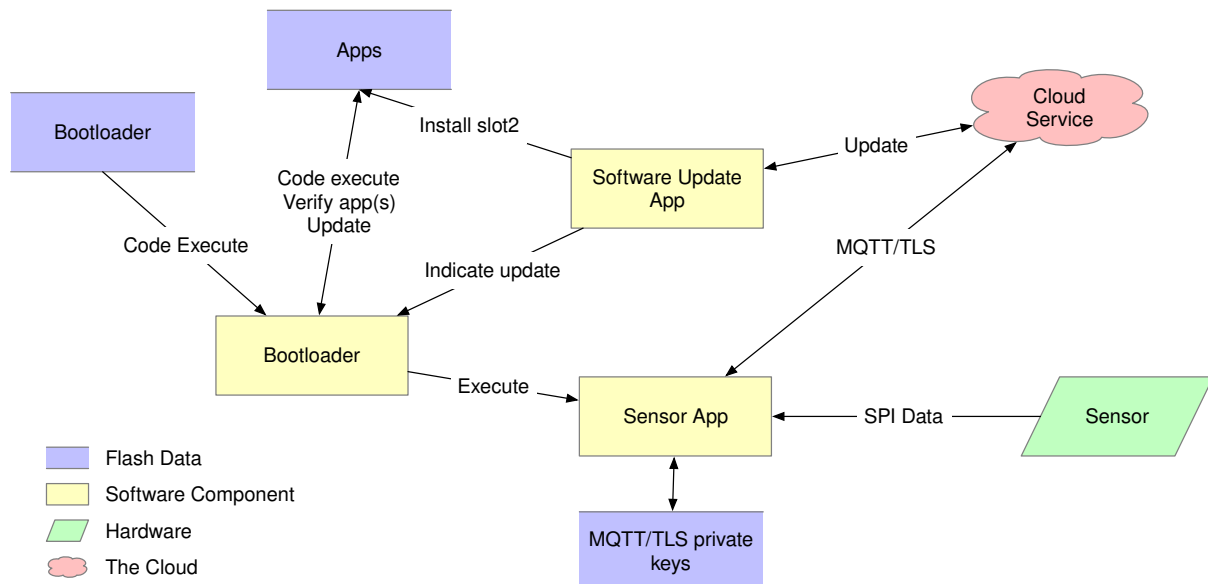

Fig. 3: Figure 1. Sensor General Diagram

In this sensor device, the sensor connects with the SoC via an SPI bus, and the SoC has a network interface that it uses to communicate with the cloud service. The particulars of these interfaces can impact the threat model in unexpected ways, and variants on this will need to be considered (for example, using a separate network interface SoC connected via some type of bus).

This model also focuses on communicating via the MQTT-over-TLS protocol, as this seems to be in wide use<sup>1</sup>.

### 9.4.1 Assets

One aspect of the threat model to consider are assets involved in the operation of the device. The following list enumerates the assets included in this model:

<sup>1</sup> See <https://www.slideshare.net/kartben/iot-developer-survey-2018>. As of this writing, the three major cloud IoT service providers, AWS IoT, Google Cloud IoT, and Microsoft Azure IoT all provide MQTT over TLS. Some feedback has suggested that some find difficulty with UDP protocols and routing issues on various networks.

1. **The bootloader.** This is a small code/data image contained in on-device flash that is the first code to run. In order to establish a root of trust, this image must be immutable. This model assumes that the SoC provides a mechanism to protect a region of the flash from future writes, and that this will be done after this image is programmed into the device, early in production [[th-imboot](#)].
2. **The application firmware image.** This asset consists of the remainder of the firmware run by the microcontroller. The distinction is made because this part of the image will need to be updated periodically as security vulnerabilities are discovered. Requirements for updates to this image are:
  - a. The image shall only be replaced with an authorized image [[th-authrepl](#)].
  - b. When an authorized replacement image is available, the update shall be done in a timely manner [[th-timely-update](#)].
  - c. The image update shall be seen as atomic, meaning that when the image is run, the flash shall contain either the update image in its entirety, or the old image in its entirety [[th-atomic-update](#)].
3. **Root certificate list.** In order to authenticate the cloud service (server), the IoT device must have a list of root certificates that are allowed to sign the certificate on the server. For cloud-provider based services, this list will generally be provided by the service provider. Because the root certificates can expire, and possibly be revoked, this list will need to be periodically updated [[th-root-certs](#)], [[th-root-check](#)].
4. **Client secrets.** To authenticate the client to the service, the client must possess some kind of secret. This is generally a private key, usually either an RSA key or an EC private key. When establishing communication with the server, the device will use this secret either as part of the TLS establishment, or to sign a message used in the communication.

This secret is generally generated by the service provider, or by software running elsewhere, and must be securely installed on the device. Policy may dictate that this secret be replaced periodically, which will require a way to update the client secret. Typically, the service will allow two or three active keys to allow this update to proceed while the old key is used.

These secrets must be protected from read, and the smallest amount of code necessary shall have access to them. [[th-secret-storage](#)]

5. **Current date/time.** TLS certificate verification requires knowledge of the current date and time in order to determine if the current time falls within the certificate's current validity time. Also, token based client authentication will generally require the client to sign a message containing a time window that the token is valid. Certificate validation requires the device's notion of date and time to be accurate within a day or so. Token generation generally requires the time to be accurate within 5-10 minutes.

It may be possible to approximate secure time by querying an external time server. Secure NTP is possibly beyond the capabilities of an IoT device. The main risks of having incorrect time are denial of service (the device rejects valid certificates), and the generation of tokens with invalid times. It could be possible to trick the device into generating tokens that are valid in the future, but the attacker would also have to spoof the server's certificate to be able to intercept this. [[th-time](#)]

6. **Sensor data.** The data received from the sensor itself, and delivered to the service shall be delivered without modification or tampering.
7. **Device configuration.** Various configuration data, such as the hostname of the service to connect to, the address of a time server, frequency and parameters of when sensor data is sent to the service, and other need to be kept by the device. This configuration data will need to be updated periodically as the configuration changes. Updates should be allowed only from authorized parties. [[th-conf](#)]
8. **Logs.** In order to assist with analysis of security issues, the device shall log information about security-pertinent events. IoT devices generally have limited storage, and as such, these logs need to be carefully selected. It may also be possible to send these log events to the cloud service where they can be stored in a more resource-available environment. Types of events that should be logged include:

- a. **Firmware image updates.** The system should log the download of new images, and when an image is successfully updated.
- b. **Client secret changes.** Changes and new client secrets should be logged.
- c. **Changes to the device configuration.**

[\[th-logs\]](#)

### 9.4.2 Communication

In addition to assets, the threat model also considers the locations where data or assets are communicated between entities of the system.

1. **Flash contents.** The flash device contains several regions. The contents of flash can be modified programmatically by the SoC's CPU.

- a. **The bootloader.** As described in the Assets section, the bootloader is a small section of the flash device containing the code initially run. This section shall be written early in the lifecycle of the device, and the flash device then configured to permanently disallow modification of this section. This configuration should also prevent modification via external interfaces, such as JTAG or SWD debuggers.

The bootloader is responsible for verifying the signature of the application image as well as updating the application image from the update image when an update is needed.

The bootloader shall verify the signature of the update image before installing it.

The bootloader shall only accept an update image with a newer version number than the current image.

- b. **The application image.** The application image contains the code executed during normal operation of the device. Before running this image, the bootloader shall verify a digital signature of the image, to avoid running an image that has been tampered with. The flash/system shall be configured such that after the bootloader has completed, the CPU will be unable to write to the application image.
- c. **The update image.** This is an area of flash that holds a new version of the application image. This image will be downloaded and stored by the application during normal operation. When this has completed, the application can trigger a reboot, and the bootloader can install the new image.
- d. **Secret storage.** An area of the flash will be used to store client secrets. This area is written and read by a subset of the application image. The application shall be configured to protect this area from both reads and writes by code that does not need to have access to it, giving consideration to possible exploits found within a majority of the application code. Revealing the contents of the secrets would allow the attacker to spoof this device.

Initial secrets shall be placed in the device during a provisioning activity, distinct from normal operation of the device. Later updates can be made under the direction of communication received over a secured channel to the service.

- e. **Configuration storage.** There shall be an area to store other configuration information. On resource-constrained devices, it is allowed for this to be stored in the same region as the secret storage, however, this adds additional code that has access to the secret storage area, and as such, more code that must be scrutinized.
- f. **Log storage.** The device may have an area of flash where log events can be written.

2. **Sensor/Actuator interface.** In this design, the sensor or actuator communicates with the SoC via a bus, such as SPI. The hardware design shall be made to make intercepting this bus difficult for an attack. Required techniques depend on the sensitivity and use of the sensor data, and can range from having the sensor mounted on the same PCB as the MCU to epoxy potting the entire device.

3. **Communication with cloud service.** Communication between the device, and the cloud service will be done over the general internet. As such, it shall be assumed that an attacker can arbitrarily intercept this channel and, for example, return spoofed DNS results or attempt man-in-the-middle attacks against communication with cloud services.

The device shall use TLS for all communication with the cloud service [th-all-tls]. The TLS stack shall be configured to use only cipher suites that are generally considered secure<sup>2</sup>, including forward secrecy. The communication shall be secured by the following:

- a. **Cipher suite selection.** The device shall only allow communication with generally agreed secure cipher suites [th-tls-ciphers].
  - b. **Server certificate verification.** The server presented by the server shall be verified [th-root-check].
    - i. **Naming.** The certificate shall name the host and service the cloud service server is providing. RFC6125 describes best practices for this. It is permissible for the device to require the certificate to be more restrictive than as described in this RFC, provided the service can use a certificate that can comply.
    - ii. **Path validation.** The device shall verify that the certificate chain has a valid signature path from a root certificate contained within the device, to the certificate presented by the service. RFC4158 describes this in general. The device is permitted to require a more restricted path, provided the server certificate used complies with this restriction.
    - iii. **Validity period.** The validity period of all presented certificates shall be checked against the device's best notion of the current time.
  - c. **Client authentication.** The client shall authenticate itself to the service using a secret known only to that particular device. There are several options, and the technique used is generally mandated by the particular service provider being used [th-tls-client-auth].
    - i. **TLS client certificates.** The TLS protocol allows the client to present a certificate, and assert its knowledge of the secret described by that certificate. Generally, these certificates will be stored within the service provider. These certificates can be self-signed, or signed by a CA. Since the service provider maintains a list of valid certificates (mapping them to a device identity), having these certificates signed by a CA does not add any additional security, but may be useful in the management of these certificates.
    - ii. **Token-based authentication.** It is also possible for the client to authenticate itself using the *password* field of the MQTT CONNECT packet. However, the secret itself must not be transmitted in this packet. Instead, a token-based protocol, such as RFC7519's JSON Web Token (JWT) can be used. These tokens will generally have a small validity period (e.g. 1 hour), to prevent them from being reused if they are intercepted. The token shall not be sent until the device has verified the identity of the server.
  - d. **Random/Entropy source.** Cryptograph communication requires the generation of secure pseudorandom numbers. The device shall use a modern, accepted cryptographic random-bit generator to generate these random numbers. It shall use either a Non-Deterministic Random Bit Generator (True RBG) implemented in hardware within the SoC, or a Deterministic Random Bit Generator (Pseudo RBG) seeded by an entropy source within the SoC. Please see NIST SP 800-90A for information on approved RBGs and NIST SP 800-90B for information on testing a device's entropy source [th-entropy].
4. **Communication with the time service.** Ideally, the device shall contain hardware that maintains a secure time. However, most SoCs in use do not have support for this, and it will be necessary to consult an external time service. RFC4330 and referenced RFCs describe the Simple Network Time Protocol that can be used to query the current time from a network time server.
  5. **Device lifecycle.** An IoT device will have a lifecycle from production to destruction and disposal of the device. Aspects of this lifecycle that impact security include initial provisioning, normal operation, re-provisioning, and destruction.

---

<sup>2</sup> As new exploits are discovered, what is considered secure can change. Organizations such as <https://www.ssllabs.com/> provide information on current ideas of how TLS must be configured to be secure.

- a. **Initial provisioning.** During the initial provisioning stage, it is necessary to program the bootloader, an initial application image, a device secret, and initial configuration data [\[th-initial-provision\]](#). In addition, the bootloader flash protection shall be installed. Of this information, only the device secret needs to differ per device. This secret shall be securely maintained, and destroyed in all locations outside of the device once it has been programmed [\[th-initial-secret\]](#).
- b. **Normal operation.** Normal operation includes the behavior described by the rest of this document.
- c. **Re-provisioning.** Sometimes it is necessary to re-provision a device, such as for a different application. One way to do this is to keep the same device secret, and replace the configuration data, as well as the cloud service data associated with the device. It is also possible to program a new device secret, but if this is done it shall be done securely, and the new secret destroyed externally once programmed into the device [\[th-reprovision\]](#).
- d. **Destruction.** To prevent the device secret from being used to spoof the device, upon decommissioning, the secret for a particular device shall be rendered ineffective [\[th-destruction\]](#). Possibilities include:
  - i. Hardware destruction of the device.
  - ii. Securely wiping the flash area containing the secret<sup>3</sup>.
  - iii. Removing the device identity and certificate from the service.

### 9.4.3 Other Considerations

In addition to the above, network connected devices generally will need a way to configure them to connect to the network environment they are placed in. There are numerous ways of doing this, and it is important for these configuration methods to not circumvent the security requirements described above.

### 9.4.4 Threats

### 9.4.5 Notes

## 9.5 Hardening Tool

Zephyr contains several optional features that make the overall system more secure. As we take advantage of hardware features, many of these options are platform specific and besides it, some of them are unknown by developers.

To address this problem, Zephyr provides a tool that helps to check an application configuration option list against a list of hardening preferences defined by the **Security Group**. The tool can identify the build target and based on that provides suggestions and recommendations on how to optimize the configuration for security.

### 9.5.1 Usage

After configure of your application, change directory to the build folder and:

```
# ninja build system:
$ ninja hardenconfig
# make build system:
$ make hardenconfig
```

---

<sup>3</sup> Note that merely erasing this flash area is unlikely to be sufficient.

The output should be similar to the one bellow:

↪	name	current	recommended	↪
↪	check result			
=====				
↪	CONFIG_HW_STACK_PROTECTION	n	y	↪
↪	FAIL			
↪	CONFIG_BOOT_BANNER	y	n	↪
↪	FAIL			
↪	CONFIG_PRINTK	y	n	↪
↪	FAIL			
↪	CONFIG_EARLY_CONSOLE	y	n	↪
↪	FAIL			
↪	CONFIG_OVERRIDE_FRAME_POINTER_DEFAULT	n	y	↪
↪	FAIL

↪	FAIL			
↪	CONFIG_STACK_SENTINEL	n	y	↪
↪	FAIL			

## 9.6 Vulnerabilities

This page collects all of the vulnerabilities that are discovered and fixed in each release. It will also often have more details than is available in the releases. Some vulnerabilities are deemed to be sensitive, and will not be publicly discussed until there is sufficient time to fix them. Because the release notes are locked to a version, the information here can be updated after the embargo is lifted.

### 9.6.1 CVE-2017

#### CVE-2017-14199

Buffer overflow in `getaddrinfo()`.

- [CVE-2017-14199](#)
- [Zephyr project bug tracker ZEPSEC-12](#)
- [PR6158 fix for 1.11.0](#)

#### CVE-2017-14201

The shell DNS command can cause unpredictable results due to misuse of stack variables.

Use After Free vulnerability in the Zephyr shell allows a serial or telnet connected user to cause denial of service, and possibly remote code execution.

This has been fixed in release v1.14.0.

- [CVE-2017-14201](#)
- [Zephyr project bug tracker ZEPSEC-17](#)
- [PR13260 fix for v1.14.0](#)

### CVE-2017-14202

The shell implementation does not protect against buffer overruns resulting in unpredictable behavior.

Improper Restriction of Operations within the Bounds of a Memory Buffer vulnerability in the shell component of Zephyr allows a serial or telnet connected user to cause a crash, possibly with arbitrary code execution.

This has been fixed in release v1.14.0.

- [CVE-2017-14202](#)
- [Zephyr project bug tracker ZEPSEC-18](#)
- [PR13048 fix for v1.14.0](#)

## 9.6.2 CVE-2019

### CVE-2019-9506

The Bluetooth BR/EDR specification up to and including version 5.1 permits sufficiently low encryption key length and does not prevent an attacker from influencing the key length negotiation. This allows practical brute-force attacks (aka “KNOB”) that can decrypt traffic and inject arbitrary ciphertext without the victim noticing.

#### CVE-2020-10022

##### UpdateHub Module Copies a Variable-Size Hash String Into a Fixed-Size Array

A malformed JSON payload that is received from an UpdateHub server may trigger memory corruption in the Zephyr OS. This could result in a denial of service in the best case, or code execution in the worst case.

See NCC-ZEP-016

This has been fixed in the below pull requests for main, branch from v2.1.0, and branch from v2.2.0.

- [CVE-2020-10022](#)
- [Zephyr project bug tracker ZEPSEC-28](#)

- [PR23737](#) fix for branch from v2.1.0
- [PR23308](#) fix for v2.2.0 (gpio patch)

#### CVE-2020-10058

##### Multiple Syscalls In kscan Subsystem Performs No Argument Validation

Multiple syscalls in the Kscan subsystem perform insufficient argument validation, allowing code executing in userspace to potentially gain elevated privileges.

See NCC-ZEP-006

This has been fixed in a branch from v2.1.0, and release v2.2.0.

- [CVE-2020-10058](#)
- [Zephyr project bug tracker ZEPSEC-34](#)
- [PR23748](#) fix for branch from v2.1.0
- [PR23308](#) fix for v2.2.0 (kscan patch)

## CVE-2020-10059

### UpdateHub Module Explicitly Disables TLS Verification

The UpdateHub module disables DTLS peer checking, which allows for a man in the middle attack. This is mitigated by firmware images requiring valid signatures. However, there is no benefit to using DTLS without the peer checking.

See NCC-ZEP-018

This has been fixed in a PR against Zephyr main.

- [CVE-2020-10059](#)
- [Zephyr project bug tracker ZEPSEC-36](#)
- [PR24954 fix on main \(to be fixed in v2.3.0\)](#)
- [PR24954 fix v2.1.0](#)
- [PR24954 fix v2.2.0](#)

## CVE-2020-10060

### UpdateHub Might Dereference An Uninitialized Pointer

In `updatehub_probe`, right after JSON parsing is complete, `objects[1]` is accessed from the output structure in two different places. If the JSON contained less than two elements, this access would reference uninitialized stack memory. This could result in a crash, denial of service, or possibly an information leak.

Recommend disabling updatehub until such a time as a fix can be made available.

See NCC-ZEP-030

This has been fixed in a PR against Zephyr main.

### CVE-2020-10062

Packet length decoding error in MQTT

CVE: An off-by-one error in the Zephyr project MQTT packet length decoder can result in memory corruption and possible remote code execution. NCC-ZEP-031

The MQTT packet header length can be 1 to 4 bytes. An off-by-one error in the code can result in this being interpreted as 5 bytes, which can cause an integer overflow, resulting in memory corruption.

This has been fixed in main for v2.3.

- [CVE-2020-10062](#)

### CVE-2020-10065

OOB Write after not validating user-supplied length ( $\leq 0xffff$ ) and copying to fixed-size buffer (default: 77 bytes) for HCI\_ACL packets in bluetooth HCI over SPI driver.

- [CVE-2020-10065](#)
- [Zephyr project bug tracker ZEPSEC-66](#)
- This issue has not been fixed.

## CVE-2020-10066

Incorrect Error Handling in Bluetooth HCI core

In `hci_cmd_done`, the `buf` argument being passed as null causes nullpointer dereference.

- [CVE-2020-10066](#)
- [Zephyr project bug tracker ZEPSEC-67](#)
- [PR24902 fix for v2.4](#)
- [PR25089 fix for v1.4](#)

## CVE-2020-10067

Integer Overflow In `is_in_region` Allows User Thread To Access Kernel Memory

A malicious userspace application can cause a integer overflow and bypass security checks performed by system call handlers. The impact would depend on the underlying system call and can range from denial of service to information leak to memory corruption resulting in code execution within the kernel.

See NCC-ZEP-005

This has been fixed in releases v1.14.2, and v2.2.0.

- [CVE-2020-10067](#)
- [Zephyr project bug tracker ZEPSEC-27](#)

- [PR23963 fix for branch from v2.2.0](#)

#### **CVE-2020-10070**

MQTT buffer overflow on receive buffer

In the Zephyr Project MQTT code, improper bounds checking can result in memory corruption and possibly remote code execution. NCC-ZEP-031

When calculating the packet length, arithmetic overflow can result in accepting a receive buffer larger than the available buffer space, resulting in user data being written beyond this buffer.

This has been fixed in main for v2.3.

- [CVE-2020-10070](#)
- [Zephyr project bug tracker ZEPSEC-85](#)
- [commit 0b39cbf3 for v2.3](#)
- [NCC-ZEP report \(NCC-ZEP-031\)](#)

#### **CVE-2020-10071**

Insufficient publish message length validation in MQTT

The Zephyr MQTT parsing code performs insufficient checking of the length field on publish messages, allowing a buffer overflow and potentially remote code execution. NCC-ZEP-031

This has been fixed in main for v2.3.

- [CVE-2020-10071](#)
- [Zephyr project bug tracker ZEPSEC-86](#)
- [commit 989c4713 fix for v2.3](#)
- [NCC-ZEP report \(NCC-ZEP-031\)](#)

#### **CVE-2020-10072**

All threads can access all socket file descriptors

There is no management of permissions to network socket API file descriptors. Any thread running on the system may read/write a socket file descriptor knowing only the numerical value of the file descriptor.

- [CVE-2020-10072](#)

- [PR27774 fix for v2.4](#)
- [PR30503 fix for v1.4](#)

### CVE-2020-13602

Remote Denial of Service in LwM2M do\_write\_op\_tlv

In the Zephyr LwM2M implementation, malformed input can result in an infinite loop, resulting in a denial of service attack.

- [CVE-2020-13602](#)
- [Zephyr project bug tracker ZEPSEC-56](#)
- [PR26571 fix for v2.4](#)
- [PR33578 fix for v1.4](#)

### CVE-2020-13603

Possible overflow in mempool

- Zephyr offers pre-built 'malloc' wrapper function instead.
- The 'malloc' function is wrapper for the 'sys\_mem\_pool\_alloc' function
- sys\_mem\_pool\_alloc allocates 'size + WB\_UP(sizeof(struct sys\_mem\_pool\_block))' in an unsafe manner.
- Asking for very large size values leads to internal integer wrap-around.
- Integer wrap-around leads to successful allocation of very small memory.
- For example: calling malloc(0xffffffff) leads to successful allocation of 7 bytes.
- That leads to heap overflow.
- [CVE-2020-13603](#)
- [Zephyr project bug tracker ZEPSEC-111](#)
- [PR31796 fix for v2.4](#)
- [PR32808 fix for v1.4](#)

## 9.6.4 CVE-2021

### CVE-2021-3320

Mismatch between validation and handling of 802154 ACK frames, where ACK frames are considered during validation, but not during actual processing, leading to a type confusion.

- [CVE-2020-3320](#)
- [PR31908 fix for main](#)

### CVE-2021-3321

Incomplete check of minimum IEEE 802154 fragment size leading to an integer underflow.

- [CVE-2020-3321](#)
- [Zephyr project bug tracker ZEPSEC-114](#)

#### CVE-2021-3581

Under embargo until 2021/09/04

# Bibliography

- [th-imboot] Must boot with an immutable bootloader.
- [th-authrepl] Application image shall only be replaced with an authorized image.
- [th-timely-update] Application updates shall be done in a timely manner.
- [th-atomic-update] Application updates shall be atomic.
- [th-root-certs] TLS must have a list of trusted root certificates.
- [th-root-check] TLS must verify root certificate from server is valid.
- [th-secret-storage] There must be a mechanism to securely store client secrets. The least amount of code necessary shall have access to these secrets.
- [th-time] System must have moderately accurate notion of the current date/time.
- [th-conf] The system must receive, and keep configuration data.
- [th-logs] The system must log security-related events, and either store them locally, or send to a service.
- [th-all-tls] All communications with the cloud service shall use TLS.
- [th-tls-ciphers] TLS shall be configured to allow only generally agreed cipher suites (including forward secrecy).
- [th-tls-client-auth] The device shall authenticate itself with the cloud provider using one of the methods described.
- [th-entropy] The TLS layer shall use a modern, accepted cryptographic random-bit generator seeded by an entropy source within the SoC.
- [th-initial-provision] The device shall have a per-device secret loaded before deployment.
- [th-initial-secret] The initial secret shall be securely maintained, and destroyed in any external location as soon as the device is provisioned.
- [th-reprovision] Reprovisioning a device shall be done securely.
- [th-destruction] Upon decommissioning, the device secret shall be rendered ineffective.
